College of Virginia, Richmond; radiologist at St. Luke's Hospital, where he died Sept. 13, aged 65, of a brain tumor.

Kochmann, Alfred Ⓜ New York City; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, 1913; specialist certified by the American Board of Otolaryngology; on the staffs of the Mount Vernon (N. Y.) Hospital and the Lincoln Hospital; drowned in Acapulco, Mexico, Sept. 25, aged 69.

Leiter, H. Evans Ⓜ New York City; University and Bellevue Hospital Medical College, New York City, 1930; specialist certified by the American Board of Urology; member of the American Urological Association; fellow of the American College of Surgeons; associated with Mount Sinai and Beth Israel hospitals, and the Hospital for Joint Diseases; consultant in urology to the Veterans Administration; died Sept. 12, aged 51.

Levin, Charles Alec, Hartford, Conn.; Johns Hopkins University School of Medicine, Baltimore, 1920; a member of the courtesy staff of Hartford Hospital, where he died Sept. 26, aged 64.

Lineberry, E. Dice Ⓜ Birmington, Ala.; born in Cliffview, Va., Oct. 5, 1901; University of Virginia Department of Medicine, Charlottesville, 1926; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians and for 9 years governor of the state chapter; served on the faculty of the Medical College of Alabama; past-president of the Jefferson County Medical Society; member of the House of Delegates of the American Medical Association from 1946 to 1948; on the staff of the Carraway Methodist Hospital; died Sept. 6, aged 56, of coronary occlusion and infarction and cancer of the rectum with metastasis to lungs and larynx.

Lockwood, Howard De Forest Ⓜ Meriden, Conn.; Yale University School of Medicine, New Haven, 1901; served as president and secretary of the Meriden Medical Society; for 30 years city medical examiner; formally city health officer; served on the staff of the Undercliff Sanatorium; served as president of the medical board and chairman of the board of directors of the Meriden Hospital; veteran of World War I; member and past-president of the Meriden Rotary Club; died Sept. 25, aged 81.

Loder, Horace Bolton, Bridgeton, N. J.; Johns Hopkins University School of Medicine, Baltimore, 1928; member of the Medical Society of New Jersey; veteran of World War II; on the staff of the Bridgeton Hospital, where he died Sept. 14, aged 55.

Long, William Hunt Ⓜ Indianapolis; Indiana University School of Medicine, Indianapolis, 1908; at one time member of the city board of health; veteran of World War I; died Sept. 4, aged 76.

Loper, John C., Bridgeton, N. J.; Jefferson Medical College of Philadelphia, 1903; physician to the city schools; on the staff of the Bridgeton Hospital; died Sept. 1, aged 76, of coronary occlusion.

McHugh, William James Jr. Ⓜ Jeannette, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1943; member of the American Academy of General Practice; school physician in Jeannette; veteran of World War II; on the staff of the Westmoreland Hospital in Greensburg; an active member of the Jeannette Memorial Hospital Association; editor of the *Bulletin of the Westmoreland County Medical Society;* a director of the Jeannette Federal Savings and Loan Association; died Sept. 17, aged 44, of coronary thrombosis.

McRae, Donald Hugh Ⓜ Detroit; Michigan College of Medicine and Surgery, Detroit, 1905; veteran of World War I; on the staff of the Lincoln Hospital, where he died Sept. 11, aged 75, of cerebral thrombosis.

MacGregor, Archibald E. Ⓜ Battle Creek, Mich.; Detroit College of Medicine, 1901; fellow of the American College of Surgeons; past-president of the Calhoun County Medical Society; served on the staff of the Leila Y. Post Montgomery Hospital, where he died Sept. 17, aged 83, of cerebral thrombosis and arteriosclerosis.

Maccani, William Louis, Ironwood, Mich.; University of Illinois College of Medicine, Chicago, 1914; served as school physician and township health officer in Watersmeet for many years, and also in the same capacity for Ironwood township; served during World War I and later with the Army of Occupation; on the staff of the Grand View Hospital, where he died Sept. 10, aged 69, of cardiorenal disease.

Maldonado, Miguel Angel Ⓜ Warren Air Force Base, Wyo.; University of Puerto Rico School of Medicine, San Juan, P. R., 1955; service member of the American Medical Association; captain, medical corps, U. S. Air Force Reserve; died Aug. 26, aged 28, of a self-inflicted gunshot wound in the head.

Marasin, Theodore Louis Ⓜ Cutchogue, N. Y.; University of St. Andrews Conjoint Medical School, St. Andrews and Dundee, Scotland, 1935; veteran of World War II; on the staff of the Eastern Long Island Hospital in Greenport, where he died Sept. 22, aged 52, of cancer of the sigmoid with metastases to the liver.

Meeker, D. Olan Ⓜ Riverside, Conn.; University of Rochester School of Medicine and Dentistry, Rochester, N. Y., 1929; specialist certified by the National Board of Medical Examiners; a member of the American Medical Association Committee on Legislation representing the New England States and was in charge of the Committee on Healing Arts for New England; served as medical director of the National Drug Company in Philadelphia and resigned to become medical consultant of the Ethical Products Division of the Ferry-Hanly Company, New York advertising agency; assistant attending surgeon at Greenwich Hospital and consultant in proctology at the Nathaniel Witherell Hospital in Greenwich, Conn.; member of the Greenwich Chamber of Commerce and Civil Council, which he served as a director and chairman of the service division; a director of the Greenwich Rotary Club and past chairman of the committee on public welfare of the Greenwich Legislative Council; died in Pleasantville, N. Y., Sept. 13, aged 57, of coronary disease.

Mills, Harry Lee, Wichita, Kan.; Central Medical College of St. Joseph, Mo.; 1904; died in the Wesley Hospital Sept. 27, aged 77, of cerebral thrombosis.

Minchew, Benjamin Harvey Ⓜ Waycross, Ga.; born in Davis in 1882; Atlanta College of Physicians and Surgeons, 1909; past-president of the Medical Association of Georgia, Ware County Medical Society, Georgia Eye, Ear, Nose and Throat Association, Atlantic Coast Line Surgeons, and the Eighth District Medical Society; served as vice-president of the Georgia Department of Public Health; fellow of the American College of Surgeons; member of the House of Delegates of the American Medical Association from 1945 to 1951; veteran of World War I; on the staffs of the Memorial and Atlantic Coast Line hospitals; for many years physician for the Atlantic Coast Line Railroad; died in Thomasville Sept. 14, aged 76.

Minkoff, Max, Brooklyn; Eclectic Medical College of the City of New York, 1911; died Sept. 25, aged 74, of mediastinal lymphosarcoma.

Moffitt, John Alfred Ⓜ San Marino, Calif.; University of Louisville (Ky.) School of Medicine, 1921; member of the American Society of Anesthesiologists; formerly on the faculty of the University of Oklahoma School of Medicine in Oklahoma City; specialist certified by the American Board of Anesthesiology; on the staffs of the Hospital of the Good Samaritan, St. Vincent's, and California hospitals, Los Angeles, and the Methodist Hospital, in Arcadia, where he died Sept. 24, aged 62, of cancer of the pancreas.

Moore, William Bain, Louisville, Ky.; University of Nashville (Tenn.) Medical Department, 1899; an associate member of the American Medical Association; died Sept. 20, aged 81, of myocarditis and uremia.

Morsman, Charles Frank Ⓜ Hot Springs, S. D.; born in Galesburg, Ill., Jan. 4, 1880; University of Nebraska College of Medicine, Omaha, 1902; fellow of the American College of Physicians, of which he was governor in 1949; member of the Endocrine Society, Radiological Society of North America, and the American Radium Society; specialist certified by the American Board of Internal Medicine; founder of the Dr. Charles Frank Morsman Foundation at the University of Nebraska College of Medicine, Omaha, which foundation was set up by him to further the knowledge of endocrinology; served as president of the local Chamber of Commerce; for many years attending physician, State Soldiers' Home Hospital; attending internist, Lutheran Hospital, where he died Sept. 25, aged 78.

Palen, Gilbert Joseph, Roxbury, N. Y.; Hahnemann Medical College and Hospital of Philadelphia, 1895; professor emeritus of otology at his alma mater; fellow of the American College of Surgeons; served on the staff of the Hahnemann Hospital; formerly superintendent of the Margaretville (N. Y.) Hospital; past-president of the Philadelphia Rotary Club; died Sept. 6, aged 88, of arteriosclerosis.

Pomainville, Frank Xavier Ⓜ Wisconsin Rapids, Wis.; Rush Medical College, Chicago, 1899; served as city health officer, mayor, and on the board of education, of which he was for one year president; veteran of World War I; local surgeon for the Chicago and Northwestern Railroad; on the staff of the Riverview Hospital, where he died Sept. 1, aged 87, of complications following an operation.

Shapiro, David, New York City; Fordham University School of Medicine, New York City, 1915; member of the Medical Society of the State of New York; served on the staff of the New York Hospital; formerly medical director of the Lumbermen's Mutual Casualty Company of New York; died Sept. 10, aged 67.

Standard, Alphonso Perry Ⓜ Macomb, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906; past-president of the McDonough County Medical Society and of the McDonough County Fair Association; served on the school board; formerly on the staff of Graham Hospital in Canton; served on the staff of the St. Francis Hospital and as chief of staff, McDonough District Hospital; charter member and past-president of the Macomb Rotary Club; died Sept. 11, aged 77, of cerebral vascular hemorrhage and embolism.

Turner, John Patrick, Philadelphia; Leonard Medical School, Raleigh, 1906; an associate member of the American Medical Association; member of the board of education; for many years police surgeon; served as trustee and in 1951 received the Distinguished Service Award of Shaw University, Raleigh, N. C.; died Sept. 14, aged 72, of coronary thrombosis.

AUSTRIA

Cystic Fibrosis.—At the meeting of the society of physicians in Vienna on Oct. 3, Dr. O. Stur reported on his experience with the plate test performed according to Shwachmann's technique and the iodized oil test performed according to Silverman's technique. The plate test, by which the increase of sodium chloride in the skin can be proved with the aid of an agar silver nitrate potassium bichromate plate, was useful in the differentiation between celiaca and cystic fibrosis of the pancreas. Differentiation could also be achieved by controlling the fat absorption with the aid of the iodized oil test before and after ingestion of a wheat-free diet and the administration of pancreatic enzymes.

Differential Diagnosis of Metastases to the Liver.—At the same meeting Dr. St. Wuketich stated that besides the known differentiation between carcinomatous and sarcomatous metastases, certain well-defined types of carcinomatous metastases can be recognized. The three main types are (1) undifferentiated (parvicellular-solid) bronchial carcinoma which is soft, homogenous, white and red-grey, interspersed, often having projecting nodules, and having hemorrhages with flat spherical segments without central indentation or with only an apparent cancerous umbilication, predominantly parvinodular, (2) the metastatic type of carcinoma of the colon with great prominence and plateau-like flattening of the nodules, macrogranulolobular structure, yellow-white due to extensive fatty infiltration and coagulation necrosis, and slight nodular confluence, mostly macronodular, and (3) the metastatic type of carcinoma of the breast, usually with only slight or no prominence of dense nodules, deep crater-like central indentation, decided confluence of the usually small individual nodules to large nodular conglomerations, generally white without extensive necrosis, and not always sharply defined. Easily recognizable are also the pigmented melanoblastomatous metastases, the hemorrhagic necrotic deposits of chorionepithelioma, and the peculiar yellow-pink metastases of hypernephroma which are often interspersed with hemorrhages. A metastatic type of endocrine carcinomas, particularly malignant carcinoids, can also be differentiated, but because only few cases have so far been observed, this is not often done.

FRANCE

Renal Biopsy.—Jean Hamburger (*Presse méd.* 66:146, 1958) questioned the innocuousness of performance of both the transcutaneous aspiration biopsy and the classic surgical biopsy of the kidney. He cited a number of accidents, particularly massive hemorrhage, from the literature. He therefore devised a mixed technique comprising in a first step the surgical approach to the outer edge of the kidney and in a second step the performance of the needle biopsy under visual control. Even though a little more complicated than the transcutaneous puncture, this technique has the advantages of direct vision, safety, and ease of performance. There was generally no hematuria, even microscopically, on the day after the operation. In the 110 biopsies so far performed in this way no accident has been noted, but the method is contraindicated when there is a hemorrhagic state or a marked renal insufficiency.

Hyperfibrinemia.—P. Croizat (*Presse méd.* 66:1471, 1958) stated that from a statistical record of 100 patients with malignant granulomatosis, lymphosarcoma, or reticulosarcoma, studied with respect to fibrinemia, it appeared that 75% of those subjects who were affected by malignant granulomatosis presented high levels of fibrinogen (5 to 11 Gm. per 100 cc.). Such values are observed in the evolutive stage of the disease, as the post-therapeutic improvements always cause the fibrin level to return to normal. Hyperfibrinemia was less severe and less frequent in reticulosarcoma and malignant histiocytic reticulosis and a little higher in lymphosarcoma.

INDIA

Kidney Function Test in Leprosy.—Gokhale and Kurkure (*Indian J. M. Sc.* 12:5 [May] 1958) stated that during the phenomenon of the reaction in the course of leprosy, exacerbations of signs and symptoms occurs which may include swelling of lesions on the hands and feet, edema of the eyelids, and such generalized symptoms as fever and malaise. The authors tested renal function by using phenol red during the reaction phase and comparing the results with those obtained during the quiescent stage of the disease. Eight patients with lepromatous and 19 with tuberculoid leprosy were thus studied. Three normal persons were included as controls. Other estimations such as the blood urea,

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

serum sodium, and serum potassium level determinations were made on a few patients. Values of phenol red excretion below 28% in the first 15 minutes were taken as abnormal. They were found to be low in 14 of the 18 patients studied during the reaction phase, but the other four gave normal values. In five patients, the excretion rate increased during the quiescent phase. In seven of those studied during the reaction, the values in the first 15 minutes did not differ materially from those obtained in the second 15 minutes. The values obtained in the patients studied in the quiescent stage were definitely higher than those obtained during the reaction. Thus some impairment of kidney function is indicated during the reaction phase. The urea, sodium, and potassium values were found to be normal or slightly elevated. The degree of albuminuria had no relation to the degree of impairment in phenol red excretion, and the blood pressure was within the normal range in all patients. The edema that appears in some patients in the reaction may thus be due to impaired renal function.

Prolonged Administration of Anticonvulsant Drugs.—S. S. Gupta (*Indian J. M. Sc.* 12:5 [May] 1958) stated that the anticonvulsant drugs must usually be used for a long time and sometimes even lifelong for control of seizures in patients with epilepsy. Diphenylhydantoin sodium and phethenylate have been found to retard growth in young rats. The authors investigated the antigrowth effect, if any, of similar antiepileptic drugs on rats fed on natural stock and a high protein synthetic diet supplemented with vitamins. The effects were studied on young and adult male albino rats fed on the two types of diet. The drugs studied were diphenylhydantoin, phethenylate, phenantoin, and methadione which were given along with the diet to different batches of rats. One batch was given no drugs and served as a control. The individual body weight was recorded every week and the average change in weight in different batches calculated.

All the anticonvulsant drugs studied retarded the growth of young rats in both groups, although the result was more marked in rats fed on a low-protein stock diet. The intake was, however, not diminished in any group. Trimethadione and diphenylhydantoin caused greater reduction in growth as compared to phenantoin and phethenylate, and this difference was less marked in rats receiving a high-protein diet. These drugs were given orally for three months. During this time, the weight of the control group remained almost constant. These drugs might cause this effect by interfering with the protein metabolism by affecting phosphorylation or they might compete with certain essential metabolites. Marked hepatotoxic effects of these drugs have also been observed in experimental study, and these may also be responsible for the reduction in weight in rats fed on these drugs. Thus they interfere with cell nutrition and metabolism affecting growth and body weight, but this effect could not be minimized in a high-protein diet supplemented with vitamins is given to the children receiving these anticonvulsant drugs.

Neonatal Thrombocytopenia.—J. B. Chatterjea and co-workers reported three cases of neonatal thrombocytopenia (*Bull. Calcutta School Trop. Med.* 6:2 [April] 1958). They had followed three women with idiopathic thrombocytopenic purpura aged 34, 26, and 19 years, respectively, during pregnancy; 2 were primiparas and one was pregnant for the third time. They came to hospital because of bleeding from the gums and purpuric spots on the body in the sixth to ninth month of pregnancy. The multipara gave a history of purpuric manifestations during her previous pregnancies but had not been treated for this condition. Chronic idiopathic thrombocytopenic purpura was diagnosed in these women on the basis of symptoms and bone marrow and blood findings. The spleen was not palpable in any of the patients. All the three babies of these mothers showed severe thrombocytopenia and petechial hemorrhages on birth. This thrombocytopenia disappeared within two weeks of birth. The petechial manifestations were mild and required no treatment. This self-limited neonatal thrombocytopenia in the babies of thrombocytopenic mothers may be due to the transmission of an antiplatelet antibody from the mother to the child.

Chronic Filariasis.—Arora and co-workers (*Bull. Calcutta School Trop. M.* 6:2 [April] 1958) studied the changes in plasma proteins and lymph proteins in 15 patients between 19 and 60 years of age who had had chronic filarial lymphedema for six months to eight years. The lymph was collected from the subcutaneous lymphatics. All patients gave a history of repeated attacks of fever with lymphangitis and swelling of the part involved. In six the edema was soft and in the others hard. The leg was affected in eight, scrotum in five, and forearm in two. The total protein, albumin, and globulin levels of the collected lymph and serum were estimated. The average total protein content of the lymph from these patients was five times higher than that of lymph from subcutaneous lymphatics in normal persons. The average albumin:globulin ratio was changed from the normal 2:1 to 1.5:1. The values for plasma protein levels were within normal range. The values indicate an increased degree of stasis in patients with chronic filarial lymphedema.

Splenectomy for Leishmaniasis.—Sen Gupta and Chatterjea (*Bull Calcutta School Trop. Med.* 6:2 [April] 1958) reported on four patients with visceral leishmaniasis who were resistant to specific therapy and were subjected to splenectomy and another patient on whom splenectomy had been performed previously but who had a relapse. The ages of these patients varied between 13 and 29 years. The duration of the disease was four to five years, and the enlargement of the spleen below the costal margin measured 5 to 9 in. All of the patients showed Leishman-Donovan bodies in the bone marrow and/or spleen puncture smear. One patient died of the operation, but the other three and the man whose spleen had been removed were again given specific treatment. All were discharged as clinically cured at the end of the specific therapy. They gained weight and their hemoglobin and leukocyte count returned to normal. A follow-up after six months or more showed that the improvement was maintained and there was no relapse. The authors believe that removal of the spleen was responsible for the prompt improvement in the blood findings and general condition, but prolonged specific treatment of the underlying disease is necessary after the operation to prevent further relapse.

Carbohydrate Metabolism and Injury.—K. B. Sehra (*Indian J. M. Sc.* 12:5 [May] 1958) stated that severe trauma may cause hyperglycemia. They studied two groups of patients—one composed of those who had met serious accidents and one of those who had undergone surgical operations. Both groups were further classified as having received severe or moderate injuries. The investigations included an intravenous glucose tolerance test, determination of the glucose assimilation coefficient, insulin tolerance test, and effect of insulin on patients whose healing was delayed. Insulin was given to such patients to control the hyperglycemia, its dose depending on the response of the subject. In all severely injured persons, the glucose tolerance was found to be diminished, and it was materially altered in those with moderate injury. The more severe the injury, the higher the blood sugar level at the peak. With moderate injury, the peak of blood sugar level was slightly elevated but restoration to the fasting level was much slower than normal. In patients with severe injury, the hyperglycemic phase was prolonged. Although the responses of patients suffering from severe accidental injury and those subjected to major operations were similar, the degree and duration of hyperglycemia were greater in the first group. The glucose assimilation coefficient was markedly lowered in all but two. Further glucose tolerance tests were made on five patients on three consecutive days to find out the duration of hyperglycemia. A quick restoration of the carbohydrate level to normal was seen in all but one. A diminution in the sensitivity to insulin as compared to normal was seen in all patients. Five who had stayed in the hospital for over a month were selected for insulin treatment and the results compared with those of another group of five patients who had undergone similar injury and whose condition had become chronic. The requirements of insulin varied with each patient. After the first week, progressively smaller quantities of insulin were required to keep the patients normoglycemic. After 30 days, all of them showed a return to normal of the carbohydrate level and insulin therapy was stopped. Along with the restoration of carbohydrate tolerance, there was also a marked clinical and roentgenologic improvement at the end of one month, and a quick and uneventful recovery occurred in all patients. Those who did not receive insulin showed variable results. There was marked improvement in one, noticeable improvement in two, and no improvement in the remaining two.

New Long-acting Sulfonamide—Sulfamethoxypyridazine.—J. G. Parekh and co-workers (*Indian J. M. Sc.* 12:6 [June] 1958) stated that absorption and excretion studies with the new sulfonamide, sulfamethoxypyridazine, in human beings have shown that the drug is readily absorbed and satisfactory antibacterial concentrations are reached within the first six hours of administration and are maintained for 24 hours. As excretion is slow, the drug has to be given at long intervals. The authors used this drug in 53 patients with fever who were suffering from upper respiratory tract infection, bronchitis, pneumonia, acute bacillary dysentery, acute otitis media, and pyelitis. Besides routine clinical examination and examination of blood, sputum, urine, and stools, blood concentrations of the drug were determined in most of the patients at frequent intervals to determine whether satisfactory antibacterial levels were reached and maintained. In severe infections, an initial dose of 2 Gm. was given followed by 1 Gm. every 24 hours. In milder cases, half this dose was given. Use of the drug was continued for 24 hours after the temperature came down to normal and in patients with dysentery, after the stools became normal. Forty-seven patients responded well to this treatment. Four of those with pneumonia who did not respond to the new drug were later controlled with penicillin. On the whole the results were gratifying, and as the dosage is small and the drug has to be given only once in 24 hours, it has definite advantages over other sulfonamides. Untoward reactions occurring in four patients consisted of skin rashes, hematuria, and psychosis.

Hypotensive Sedative from Vinca Rosea.—U. K. Sheth and co-workers (*Indian J. M. Sc.* 12:7, [July] 1958) stated that the presence of a hypotensive alkaloidal fraction in Vinca rosea has been reported by various authors. This perennial plant grows abundantly all over India. The authors extracted the sundried plant with alcohol and isolated the most active fraction, which has been named V-22. It was injected intravenously in dogs, cats, monkeys, and mice. The effect of the injection was evident in dogs in 5 to 10 minutes. Urticaria and itching appeared first, followed by rapid respiration and shivering. Within 10 to 15 minutes, they became quiet, lost active interest in the surroundings, and, if left alone, went to sleep. This sedative effect lasted for four or five hours, and within 24 hours they regained normal activity. Some developed a temporary diarrhea. Similar effects were observed in cats and monkeys. In mice, sedation appeared after 30 to 60 minutes and lasted for only two hours. The effect of V-22 was studied on isolated segments of guinea pig ileum. The alkaloid counteracted the spasm of the intestine produced by acetylcholine and histamine but did not counteract the spasmogenic effect of barium chloride. It failed to have any effect on the tone and movements of the uterus in rats.

The effect on blood pressure was studied on 20 anesthetized mongrel dogs. With intravenous injection of the alkaloid, a gradual fall in blood pressure occurred, preceded by a slight rise, the fall appearing after a latent period of 30 seconds, the blood pressure reaching about 53% of the original level. The reading then returned to 68% of the preinjection level in two hours and 75 to 80% at the end of four hours. Bradycardia was observed in nonatropinized dogs. The fall in heart rate was 35% immediately after the injection and returned to the original level at the end of two hours. Bradycardia was abolished by injection of atropine or bilateral vagotomy, but the fall in blood pressure was still produced. The bilateral carotid occlusion reflex disappeared completely after injection of V-22 and returned partially at the end of two to four hours. The response to an injection of epinephrine was not altered by the injection of V-22, the blood pressure was unaffected in the case of spinal cats (cats in whom the cord has been transected). In the spinal cat receiving levarterenol by drip injection, giving V-22 caused a small fall in blood pressure which returned to the original level almost immediately. No ganglion blocking effects were noticed when the alkaloid was used on the nictitating membrane of dog. Its effect on isolated frog's heart was studied. At a concentration of 1:150,000, the amplitude of contraction gradually diminished in three minutes. With concentrations of 1:100,000 and 1:50,000, marked inhibition of the heart followed by stoppage was observed. Similar effects were noticed on isolated Langendorff leporine and feline heart preparations. V-22 probably is a mixture of alkaloids.

Action of Acetazolamide on Blood Vessels.—C. L. Pathak (*Indian J. M. Sc.* 12:7 [July] 1958) stated that the diuretic action of acetazolamide is believed to be due to electrolyte washout as a result of inhibition of carbonic anhydrase in the renal tubules. While studying the effect of this drug on heart muscle, it was found that it had a biphasic effect, stimulating the heart muscle in lower concentrations and inhibiting it in higher concentrations. The author studied its action on the smooth muscles of blood vessels, using decapitated frogs and hindleg vessels of dogs. A significant vasodilator effect was noticed in 62.5% of the trials in frogs, while in the remaining a vasoconstrictor effect was obtained. The intensity of the effect varied with the dose. A similar result was obtained in dogs, a vasodilator effect being seen in 31 and a vasoconstrictor effect in 7 trials, but the intensity of vasodilatation was less marked in vessels of dogs than in those of frogs. This variable vascular response seemed to depend on the initial tone of the vessels. Thus, if the vessels were previously in a state of constriction, a vasodilator effect was more frequently seen, and if they were previously dilated, vasoconstriction was more common. The dilator effect was also more commonly seen with small doses and the constrictor effect with large doses. Thus the drug had a significant action both on amphibian and mammalian vessels, the effect being biphasic. Acetazolamide is a powerful carbonic anhydrase inhibitor, and the latter is present in many tissues, including muscle. The action on smooth muscle may be directly on the contractile mechanism or through the carbonic anhydrase inhibitory mechanism or both may be operative at different dose levels, giving a biphasic effect.

SWEDEN

Thoracic Surgery Team Tours South America.—A group of Swedish surgeons, headed by Prof. Clarence Crafoord, left in October for a two months demonstration tour in South America. The team consisted of eight surgeons, a secretary, an operating room nurse, and two technicians; 1,400 lb. of surgical instruments, including the heart-lung machine, developed by Professor Crafoord, Dr. Ake Senning, and their technicians, were carried. The Elema mingograph, an instrument for the direct continuous reproduction of cardiac waves on a moving tape and used for the registering heart movements and blood pressure, was also taken. The team visited Argentina, Brazil, Uruguay, and Chile.

The Linnaeus Autobiographies.—Five autobiographies were composed at different times by Sweden's great botanist, Carl von Linné, who was also a physician and all-around scientist. At the instigation of the University of Uppsala, Malmeström and Uggla collected and edited these autobiographies, which are published by Almquist and Wiksell of Stockholm. Linnaeus was only 27 when he completed his first autobiography. His second followed 13 years later. Most of his third and longest autobiography was dictated to his disciple, Peter Löfling. A reason given for his fourth autobiography was that as a newly elected member of the Academy of Sciences in Paris in 1762 he had to present it with a review of his life's work. He may, perhaps, have been possessed by vanity, as suggested by the secretary of the French Academy, but he was also driven by an urge to get to the root of whatever he studied, and his study of himself could not fail to reveal a man of gigantic talents. Elected a member of 19 academies and corresponding with hundreds of fellow scientists all over the world, his intellectual industry was prodigious, and if at times he took his hat off to himself, his fellow beings should rather follow suit than grudge him this homage to genius.

Treatment of Delirium Tremens.—*Svenska läkartidningen* for Sept. 26 contains a report on hydroxydione sodium succinate by several members of the staff of the Beckomberga Hospital, which has a special department devoted to patients with delirium tremens. Here, various steroids have been tested since 1952, but the death rate was high (2 of 8 patients so treated in one six-month period and 4 of 14 in another died). With the introduction of hydroxydione, a synthetic steroid with a strong sedative and anesthetic action, there were no deaths among 15 patients. The present report concerns seven particularly severe cases treated successfully. The drug was given as a 0.1 to 0.4% solution with 5% glucose in Ringer's solution as a slow intravenous drip under continuous supervision by a physician. The total amount of the drug varied from 1 to 6 Gm., and the treatment was maintained for 5 to 22 hours. In every patient profuse sweating, muscular twitching, and general tremors disappeared soon after the injection was started. Thrombophlebitis developed invariably in the recipient vein, but it passed off in a few days without special treatment. There were no other complications. Though hydroxydione is said to reduce the blood pressure, the general circulation improved in this group of patients.

Smallpox Vaccination.—According to Dr. A. Espmark (*Svenska läkartidningen*, Oct. 3, 1958) the chief hazard of smallpox vaccination is encephalitis. This risk is less in Sweden than in many other countries, but it is not negligible. In the decade 1948 to 1957, 25 cases of postvaccinal encephalitis were reported with only two deaths, whereas elsewhere this disease has shown a case fatality rate of about 40%. In Sweden, as elsewhere, those aged 6 and 7 showed a greater liability to this complication than did the younger children, but by and large the risk after primary vaccination may be put as low as 1 in 50,000 in Sweden. Espmark noted that recent comparisons of the scarification and multiple-pressure methods of vaccination have been most favorable for the latter, with 83% effective vaccinations as compared with 74% for the scarification technique. The recent introduction of plastic ampuls as containers of vaccine has helped to facilitate the dosage and technique of vaccination.

The Shortage of Physicians and Nurses.—The shortage of district health officers is so great that 9 of 30 such appointments are vacant in one county and 9 of 24 in another. As for the mental hospitals, only about 50% of their medical staff are fully qualified for the posts they hold, half being vacant or held by stopgaps. As for the shortage of nurses, it is the worst problem confronting medicine at present, with whole hospital departments closed for want of nurses. Yet in Sweden there are 27 schools of nursing which in 1957 graduated 1,450 nurses. Two services are especially handicapped by this shortage. The one deals with patients who have chronic diseases for whom the calls made on nurses are often most exacting. The other is the teaching hospital with patients whose ailments may require highly specialized nursing and frequent rounds by the physicians in charge. Two new schools of nursing, planned to serve the County of Stockholm and the town of Malmö, respectively, will, it is hoped, help to relieve the present shortage.

Treatment of Venereal Disease at Sea.—In the Swedish merchant service the care of the sick on board ship is usually allotted the second mate who is required to keep a log of his medical activities. He must have had 40 hours of medical training before taking his mate's certificate and another 40 before his captain's certificate. About 10 of these hours deal with venereal diseases. To find out how he has fared with this background, 56 mates from Swedish vessels were questioned with regard to their experiences in 1957. Their answers were analyzed by Dr. A. Björnberg and co-workers (*Svenska läkartidningen*, Oct. 3, 1958). In addition to the 365 men treated for a urethral discharge, 32 were treated for genital sores and 6 for inguinal buboes. Penicillin was given in most cases, and it was exceptional for streptomycin, chlortetracycline, and sulfonamides to be given. Only three of the patients with genital sores received more than 1,000,000 international units of penicillin, so it is probable that the dosage was usually inadequate for syphilis, but it was presumably adequate for gonorrhea. Fourteen mates had given prophylactic treatment with penicillin by injection or in tablet form as a matter of routine after shore leave, with what were presumably dubious results; 15 had neglected to advise their patients to undergo a medical check-up later; and 16 had failed to keep any record of their therapeutic activities. The questioning of these 56 mates left the general impression that stricter rules for treating venereal disease on board ship are desirable. Prophylactic tinkering should be discouraged, and when treatment is given the patient should receive an explanatory pamphlet on venereal disease and should be advised to obtain a medical check-up as soon as possible. Treatment of venereal disease by ships' mates should always be regarded as an emergency measure and should not be undertaken when treatment by a physician is available.

CORRESPONDENCE

TOXICITY OF IPRONIAZID

To the Editor:—As one of many clinicians who has had gratifying and often dramatic results with iproniazid in the treatment of depressions and melancholia, I welcomed the editorial concerning this drug in The Journal (168:50 [Sept. 6] 1958). I wish to comment on two points discussed in the editorial—dosage in relation to toxicity and the risk versus the severity of indication. Concerning the first point, the statement that "because the incidence of toxic manifestations (particularly jaundice) may be dependent on dosage" is not borne out by the evidence. From a thoroughgoing study of the reported incidence of hepatitis and fatalities from hepatonecrosis during iproniazid therapy, it is unfortunately clear that no dosage-toxicity relationship can be demonstrated at the present time. The implication that only in institutionalized patients is adequate supervision possible and a maximal initial dose of 150 mg. warranted is also not in keeping with clinical experience.

Dr. Nathan Kline and I have emphasized repeatedly that a starting dose of 150 mg. is, in fact, necessary whether the patient is treated in or out of a hospital. If an inadequate dose is given, the response to iproniazid may be delayed to the point of greatly increasing the danger of suicide, thereby defeating the very purpose of therapy. In our efforts to discover means of eradicating the factors that may induce hepatitis, we have found that by adjusting the dosage downward soon after treatment is started, it is reasonable to expect the prevention of adverse side-effects; yet it may not be possible to prevent these in the rare supersensitive patient.

Weighing the risk against the severity of the indication is another case in point. It is worthy of mention that, on the basis of the reported suicidal deaths in the United States (an incidence of 10 per 100,000 in 1956), deaths erroneously reported as accidental, and unknown cases which escape diagnosis, it is estimated that more than 20,000 will destroy themselves this year. It is well known that many suicides occur among people with frank mental illness, notably depressions. In a recent British study depression was diagnosed in 72.5% of men and 73.8% of women attempting suicide in two hospitals in Oxford, England. In an American study an analysis of case histories covering neurotic, psychotic, organic, and miscellaneously classified subjects, a diagnosis of reactive depression or of paranoid schizophrenia distinguished all suicidal patients.

In an editorial in The Journal (150:696-697 [Oct. 8] 1952), calling attention to suicide as a leading cause of death, deep moods of depression, active conflict, anxiety, and withdrawn resignation are emphasized as especially significant in persons with suicidal inclinations. If we make the conservative assumption that only a third of the 20,000 estimated suicidal patients for 1958 are suffering with some degree of depression we can speculate on what might happen if these 6,000 patients were placed on therapy with iproniazid. According to the present estimated morbidity and mortality figures associated with iproniazid therapy, a maximum of two of these 6,000 patients might be expected to develop jaundice. These two patients then have a 75% chance of surviving hepatitis without serious consequences. Let us assume for the moment a 10% efficacy of iproniazid treatment in depressed patients (and some have claimed better than 80% effectiveness of the drug). In that case of 6,000 patients, roughly 600 would have a chance to survive 1958 without committing suicide, if they were treated with iproniazid. Actually, we may expect that many more than the 600 might remain alive if iproniazid were administered to all who were depressed.

A comparison with another mode of treatment of depressions, i. e., electroshock therapy (EST), will disclose that the "calculated risk" of mortality is markedly less with iproniazid than with EST which, as demonstrated by Impastato, is 1 per 1,000 patients treated with EST. From the most reliable statistics available, Jolly estimated that the mortality with iproniazid is 1 in 16,000 to 25,000 patients under treatment. Thus, according to our present knowledge, iproniazid is at least 16 times safer than the only other acknowledged treatment for preventing suicide in melancholia. Quite apart from mortality is the fact that during EST the necessary loss of time from employment (5 or 6 weeks) may militate against the patient's retaining his job, a factor crucial to eliminating the melancholia and to preserving his life. Furthermore, one can hardly ignore the economic factor involved, both in the loss of time from work and the three times higher cost of EST, as compared with that of iproniazid therapy.

Pursuing the argument of extent of risk, it is enlightening to examine the case for tonsillectomy, the most common of surgical procedures. Based on several studies, the death rate is reported to be from 1 in 2,000 to 1 in 10,000. Yet, tonsillectomy is considered a safe procedure. In various other frequently used medical and surgical procedures, mortality is a calculated risk of even a higher order.

SOCIAL SECURITY—BARGAIN OR BUST

To the Editor:—The activities of the 85th Congress have been fateful ones for the medical profession. We have witnessed a budget battle, an economic recession, a lifted debt ceiling, plus the menace of inflation and a further devaluation of the dollar—an atmosphere ideal for perpetuation and expansion of the welfare state and the further invasion and partition of American medicine by the federal government. The disposition of the Forand Bill in no way mitigated the danger, for one can be sure that similar bills will be introduced in the near future.

There are only two ways to expand any welfare program: one, by larger cash benefits and, two, by providing greater service. The only social security field not yet exploited is that of medicine, nursing, and hospital care. Even here the door is not securely closed, for Medicare is constantly expanding, and fixed fees for services are the pattern of health insurance companies. In the 85th Congress more than 600 such bills were introduced bearing directly or indirectly on the profession. Over half dealt with amendments to the social security act and deferments or exemptions for health and welfare pensions.

If social security is such cheap insurance, why would any individual or group oppose it. To illustrate, let's take a young physician under 30 years of age. He selects a life insurance policy which meets his personal needs and, before signing, knows the annual premium and exact benefits and has a waiver of premium which will continue coverage without further cost should he be incapacitated for a prolonged time. To prevent any misunderstanding, he has a written contract backed by the strongest laws in the country. Further, his policy may be dropped or added to at his own discretion, has a definite cash value, and represents a nationally acceptable form of collateral.

By contrast, should compulsory social security for physicians become a reality, the same young man would become part of a system with an accrued liability of over 300 billion dollars. He would have no contract and would be subject, without recourse, to changes in both the tax rate and tax base. He would be forced to continue contributions unless the law was repealed or the system collapsed. His so-called insurance would have no cash or collateral value, and he could not, as he saw fit, indicate the beneficiary if, in fact, there be any at all. Being self-employed he would not have the advantage of taxes paid on his behalf by an employer. He would, in fact, be required to pay the full employee tax plus one-half of what an employer would pay. Should he be married and die, his widow will receive $225 for burial and nothing more until age 62, unless she has children under 18. Should it be necessary for her to work, her earning capacity is limited to a set sum if she is to receive benefits.

The doctor may well ask how all this came about and how social security, which was originally intended to provide "a floor of protection" for a small group, is now a giant threat to personal saving and likely to eventually turn the entire population into government wards in any medical emergency and in old age. A clue to the answer may be found in the following statement: "Twenty years ago social security was thought of as just a guarantee of bread. Today most Americans depend on it as the foundation of their retirement plans." Dr. Burrill B. Crohn feels that if the constant demand on physicians to certify people over 50 years of age as completely disabled in order to collect social security continues, we'll make fools of ourselves and further bankrupt the social security system.

INTERNSHIP

To the Editor:—Recently (*J. A. M. A.* 168:693-694 [Oct. 4] 1958), there appeared another article on the problem of internships. This problem has been stated by all parties concerned except the one most important and most inarticulate—the intern. From his standpoint, the shortage is fictitious. Hospitals which consider him a service will always have trouble filling, and nothing can or should be done to ease their plight. Actually, they should be removed from the approved list.

The only really justifiable purpose of the internship (other than the iatrogenic one of fulfilling the law of the state in which one desires to practice) is to provide a continuation of practical education. This is well worded by Jeghers (*New England J. Med.* 259:718-720 [Oct. 9] 1958): "Didactic knowledge and work experience gained in student days in medical school have no permanent value until the physician intern assumes the responsibility for their application, and is permitted to make independent decisions, subject to careful scrutiny by those who guide and supervise him." Hospitals which provide this opportunity have no difficulty in "filling" their quota of interns. Indeed, "spots" on the house staffs of such hospitals are eagerly, competitively sought after.

There are, however, only two kinds of internships. One kind is the "teaching" internship—so much teaching that the intern has no time to learn—lots of conferences, journal clubs, and lectures. The other is the "doing" type. In this type he has almost unlimited responsibility, is "turned loose," and learns from his errors or stumbles along constantly in error—overloaded with work. In their extremes, both serve their purpose and usually "fill," each with the types of personalities which uniquely fit into such situations. Then there are the internships which combine the undesirable features of each. They provide little or no teaching and little chance for actual practice. The word quickly gets passed around, and soon these hospitals are experiencing the much publicized "intern shortage."

The ideal internship would combine the desirable features of each. It would be rich in clinical material, afford opportunity to assume responsibility, and have an enthusiastic teaching staff for guidance. This internship would fill easily. There are too few of these. In fact, I have not found one!

MISCELLANY

NOAH WEBSTER—EPIDEMIOLOGIST

Herbert Thoms, M.D., New Haven, Conn.

Philatelists who collect stamps bearing a relation to medical history should interest themselves in the 4 cent Noah Webster bicentennial stamp in the "Famous American" series placed on sale Oct. 16, 1958, in West Hartford, Conn., Webster's birthplace. Noah Webster's great contribution to medicine was his study of epidemiology, particularly that of yellow fever. It was the terrible epidemic of this disease in 1793 in Philadelphia that chiefly stimulated his interest in the problem. He had observed epidemics in New England before this, influenza in 1789 and in 1790 and scarlet fever in 1793. Webster collected a large part of his data by means of circular letters sent to physicians in all parts of the United States and by extensive correspondence with leading teachers of medicine. By January, 1798, he had collected the literature on epidemics throughout the world by visiting libraries in New York and Philadelphia and at Harvard and Yale. On April 10th of that year he wrote in his diary, "Begin to write up my History of Epidemic diseases from material which I have been three months collecting."

The next year, in December, 1799, the "History of Epidemic and Pestilential Diseases" was published at Hartford. It had no great popular success and the author himself two years later estimated that he was out of pocket some $800 on its account. Nevertheless, according to the late C. E. A. Winslow,[1] these two volumes represent the best general summary of epidemiologic opinion at the beginning of the 19th century. According to this authority, "The first step in any science must, however, be the stage of observation. Noah Webster labored at this stage of epidemiology. He was dominated by theories which were inadequate and his methods of analysis were essentially unsound. In both of these respects he represented the age in which he lived. He understood, however, the vital importance of factual data." The essence of Webster's contribution to epidemiology is found in his own words, "As facts are the basis of human knowledge, it is of great importance to collect them. There are probably in every profession, facts enough which occur every year, in our extensive country, to constitute a mass of information, if collected, equal to what a long life of experience would be necessary to acquire for any one man. If not collected these useful facts are lost to all the profession, except to few individuals; if collected, they condense the knowledge of a whole life into the compass of a few hours reading. This might be done every year, and what could be more useful?"

Noah Webster was a man of highest vision during the years of this country's greatest expansion. He was truly representative of what Edward Weeks calls the "bigness of one" at a time when for America everything seemed to be on the move—in education, letters, science, medicine, exploration, and political life. This has been called our golden era, times that produced great men and vice versa, but no one outshone Noah Webster in his ability to bring his advanced thinking into practical application. He believed in a glorious future for his country and spent his life doing something about it.

Webster's studies in epidemiology were made when he was in so-called retirement but never was a word so misused. In 1798 he had given up

---

Emeritus Professor of Obstetrics and Gynecology, Yale University, and Curator, Yale Medical Memorabilia, Yale Medical Library.

his editorship of *The American Minerva* (later *The Commercial Advertizer*) which had kept him in New York for the previous five years. He had come to New Haven to devote himself to what he called literary pursuits. To be listed among these activities was serving in the General Assembly for nine sessions (1800-1807), as Councilman of New Haven (1799-1804), as Alderman (1806-1809), and as Judge of the County Court from 1806 to 1810. In 1812 he removed to Amherst, Mass., and it was not long before he was serving as a member of that commonwealth's General Court (1814, 1815, and 1817).

By 1822 Noah Webster was back in New Haven, and here until his death in 1843 he made his home. His house, formerly on Temple Street, is now one of the buildings reassembled at Greenfield Village, Dearborn, Mich.

Robert French[2] gives us this picture of his final years:

> It was a full life on the whole, which this homespun scholar made for himself, with the gay serenity of Becca (his wife) smoothing the sharp edges of his individualism. He was sixty-six when he finished his dictionary, and he gave the rest of his life to the labor of revision, getting out one further edition before his death. He died while still at work upon his great book, on the eighth of May, in 1843, at the age of eighty-four. As we look back upon the labor he performed, his slight figure, in the sober black, he seems to grow larger and to take on richer colors. This little man, too, was one of the giants of our early history. By his sole strength he wrought great things, in the face of many difficulties, and built his personality into the foundations of our country.

It is interesting that the town of West Hartford has given birth to two distinguished epidemiologists, neither of whom practiced medicine nor had a degree of doctor of medicine, Noah Webster and William Thompson Sedgwick. Both were Yale graduates, Webster in 1778 and Sedgwick almost a century later in 1877.[3]

As an epidemiologist Webster has specific interest for those of us in medicine, but be is known world-wide as our greatest lexicographer. At various times in his career he was soldier, schoolmaster, lawyer, lecturer, journalist, editor, legislator, and statistician.

Fortunately for Noah Webster, in his "retirement" he was financially secure due to the publication of his famous spelling book. Some idea of this best seller can be gained from the fact that by 1865 its sales had reached 42 million dollars. Nothing very spectacular about Webster's college career has been recorded except the day when Washington visited New Haven on his way to take command of the American Army before Boston, on which occasion Webster played a fife for a company of students that escorted him to the edge of town. At another time, a year before his graduation in 1778, he marched as a volunteer in his father's militia company against Burgoyne, being met on the way by news of his surrender.

On leaving college Webster taught school in Hartford, at the same time reading law, and was admitted to the bar in 1781. As no openings in that profession seemed to appear, in May, 1782, he opened up a select school at Sharon, Conn., and later taught at Goshen, N. Y. It was in the latter place that he began the compilation of elementary textbooks for teaching the English language, the spelling book, grammar, and reading book, which were to make his name a household word. In 1783 he was back in Hartford arranging for the publication of these works. His teaching days were not over, for he spent the year of 1787 at Philadelphia at an Episcopal academy. Two years later he was back in Hartford, this time as a lawyer, and in 1789 he married Rebecca Greenleaf of Boston. In 1793 he removed to New York to the editorship which has been mentioned.

In the revision of his most famous work, the dictionary, he had assistance from many quarters. For us it is interesting that two of his more important collaborators were Dr. Thomas Miner of Middletown, "perhaps the most learned physician in New England," and Dr. James Gates Percival of New Haven, the astonishing linguist, physician, geologist, and poet. The former was co-author with William Tully of the widely read "Essays on Fevers." The latter devoted some years to the reading of proof sheets of Webster's dictionary and, according to his own testimony, took more pleasure in the work than anything else that he did in his extraordinary and complicated life.

The Webster likeness on the new stamp is a reproduction of a lithographed print of a painting by James Herring (1794-1867), a London-born American artist who did a number of canvases of Webster. It was engraved by George Parker of the Bureau of Engraving and Printing.

BUSINESS PRACTICE

This is the seventh in a series of excerpts from the brochure on the Business Side of Medical Practice, prepared by the American Medical Association in cooperation with the Sears-Roebuck Foundation.

PROVIDING GOOD MEDICAL SERVICE

When a doctor has equipped his new office, he must set up the kind of operation that will enable him to provide the best medical service including systems to assure telephone accessibility; receive patients and make appointments; record medical information; and provide laboratory and diagnostic services.

Telephone Accessibility

The telephone has become the lifeline to a physician's practice. Unless patients can get in touch with their doctor quickly, valuable minutes can be lost with tragic consequences and the kind of rapport a physician seeks to develop with his patients destroyed. In the early days of his practice, the sound of the telephone is a happy one to a doctor—eventually he may come to regard its ringing less joyfully. But he is bound to it by his profession; it is an ear-oriented radar on which his comings and goings are traced by his patients, the hospital, and his family.

Like the installation of any other piece of office equipment, the physician will want to give thought to placing telephones where they are most easily accessible. Even though he may not employ a receptionist to take incoming calls during the early days of his practice, he will want to provide for the day when he does. Placement should assure a maximum of privacy for all conversations. The telephone company can offer good suggestions regarding installation and placement. There is also some special new equipment—devices to cut down conversational carry-overs and receiverless phones which the physician may also wish to investigate.

To cover his practice around the clock, the physician probably will want to subscribe to some form of telephone answering service. Such services answer all calls phoned to the doctor's office after office hours via a special outside switchboard. When the doctor leaves his office, he telephones the answering service and asks them to take over his calls, notifying the switchboard about where he can be reached in an emergency. The answering service records information on all calls and relays messages to the M.D.

There are various kinds of telephone answering systems, some commercially operated, others run by medical societies. The reliability of an answering service should be checked before subscribing to it.

Special equipment is also available in areas where no answering services exist. A recording device can be secured and attached to the office telephone which automatically answers the phone and notifies the caller that the doctor is out. A recorded voice invites callers to leave a message, or the doctor himself, may record a message which he dictates into the machine before he leaves and which is relayed mechanically to all callers. Some physicians in isolated sections even are installing radio equipment or mobile telephone systems in their cars so that messages can be transmitted to them while they are in transit. In a few large cities, a service "pages" a physician with a tone signal from a small pocket receiver he carries with him. The signal sounds to notify him to call his home or office for messages. All these plans are part of an effort by the medical profession to make sure a patient can reach his own doctor or secure substitute medical service in an emergency.

Formal medical society emergency programs, utilizing various telephone answering system arrangements, are being conducted in many parts of the United States. Via these programs, the medical society either locates the patient's own doctor or puts the caller in touch with another physician who will accept an emergency summons. Usually all members of a medical society, regardless of specialty, are asked to serve on the society's emergency call panel for a night, a 24-hour period, or other short intervals; that is, they are asked to stand by during these times to take emergency calls from persons who cannot reach their own doctors or who have no physician of their own. Many medical societies rely on new physicians to help operate such emergency call programs since younger men have more time available. The acceptance of emergency calls from persons without doctors may also help to build the practices of younger men.

Phone Book Listings.—The county medical society can inform a physician of the custom locally in regard to listings in the telephone directory. In some places physicians are listed by name only; in others, specialty listings are customary. Many doctors list both their office and home phones, but it is possible to arrange with the telephone company to divert office calls to a physician's home when the office does not answer. This enables a physician to retain a certain degree of home privacy, yet gives him round-the-clock telephone coverage.

The importance of utilizing the telephone properly cannot be overestimated in medical practice. The telephone should never be left unattended. A pad and pencil should always be placed beside it so that all messages can be jotted down. Courtesy should be a telephone by-word in the medical office and techniques for handling all calls worked out in the best public relations manner. Additional tips for telephone technique can be secured from the A. M. A.'s Department of Public Relations and from its publications, such as "Rx Public Relations" and "Winning Ways with Patients," available on request.

Receiving Patients and Scheduling Appointments

Even though a new physician cannot always arrange for a full-time receptionist to greet all callers to his office, he should work out some means of welcome. He himself may be busy with other patients in the inner office and be unaware that someone has entered the reception room. Patients who enter a deserted waiting room are uncertain of how to signal the doctor that they have arrived. A register in the reception room with a sign saying, "Please sign the register when you arrive. Doctor will see you shortly," or, "Please ring the bell for the receptionist and be seated. The doctor will see you in a few minutes," is reassuring and the next best thing to a personal welcome.

The doctor who employs a receptionist should train her in the art of welcoming patients. Her desk should be placed so that she can see all newcomers yet converse with patients with some degree of privacy.

Seeing Patients on Schedule.—Although some physicians in rural areas still prefer to hold "general office hours," more and more medical men today work by appointment system. Even though emergencies make it difficult to conform to a rigid appointment schedule, a flexible system is more widely accepted today for several reasons: 1. The doctor can make more efficient use of his own time when he works according to a prearranged schedule. 2. He can see more patients with less strain. 3. He can work with a smaller, less costly reception room when he does not have to accommodate all the patients who arrive under a "general office hours" system. 4. He saves the patients considerable waiting time and thus eliminates one of the biggest complaints about the medical profession.

Good management calls for making the best use of your time. Efficient scheduling of appointments reduces the strain on the doctor and increases his ability to give his patients the best medical service. A professional management official reports that a physician who switched to the appointment system saw one-third more patients in a month's time than previously, but he was not aware of it because he did not feel pushed.

Here are some tips for scheduling appointments efficiently: 1. Arrange office hours to fit community needs. Some doctors hold evening office hours two or three times a week for the convenience of working patients. 2. Schedule all appointments tactfully, considering the patient's desires. 3. Use an appointment book marked off in given time intervals. Adjust the schedule to fit the practice, allowing ample time for various types of visits, such as first visits, check-ups, specified procedures. 4. Don't make conflicting appointments. 5. Don't overcrowd the schedule. Allow two or three "breathers" during the day for catching up or resting. 6. Schedule house calls realistically at hours not conflicting with office hours. 7. Fit referred patients and patients without appointments into your schedule as best you can. 8. When it is necessary to refuse an appointment, always explain why. 9. When an emergency takes the doctor out of the office, explain the situation to waiting patients; give them the choice of waiting or returning at another time. 10. If it is necessary to cancel an appointment, notify the patient and make a new appointment. 11. Give the patients written or oral reminders of appointments.

Every physician wants his patients to feel that, when they really need him, he is available. But he must impress on his patients that the emergency should be a real one, not merely an excuse for not having made an appointment. Both the physician and his receptionist must learn to evaluate all so-called emergency calls properly. Some calls can wait until morning; others require immediate attention. Best advice for new physician: when in doubt, check it out!

Medical Records

To preserve all the necessary information about patients, their illnesses and treatments given or recommended, the physician must maintain accurate, detailed medical records. Good records not only protect the patient, assuring continuity to his care, but protect the physician should he have to go to court in connection with a professional liability or insurance action.

Medical records provide a continuous story of a patient's progress. To the physician's own case history are added reports of laboratory tests, x-rays, and other data completing the medical picture. All this information provides important clues to diagnosis and treatment.

Types of medical records vary, depending on the doctor's specialty. For example, the general practitioner and internist will keep more detailed records than the dermatologist or radiologist, who may see a patient only on a referral basis. Printing companies offer a variety of record forms.

In offices where detailed histories are not necessary, cards of various types can be used to record vital information. On these cards such information as the patient's name and address, chief complaint, onset and course of the condition, and findings of physical examinations and laboratory tests, as well as diagnosis and treatment, can be listed.

Space is limited on such cards, and consequently more medical offices are using letter-size forms on which more information can be recorded. Forms designed for various specialties can be obtained, though some physicians prefer to draw up their own forms and have them printed to order. Some doctors do not use a printed form but develop an outline for taking case histories. The information secured from patients is later typed on regular paper and filed.

Whatever form of medical record a physician adopts in his office, it should contain the following kinds of information:

1. General information about the patient: full name (correctly spelled), home and office address, telephone number, date of first visit, age, marital status, occupation, name of person responsible for the medical bill, and the name of the person who referred the patient.

2. Information about the patient's past medical history: illnesses, operations, physiological defects, allergies, and personal health habits.

3. Information about the patient's family: physical condition of members of his family, past illnesses or diseases of individual members, and causes of death of family members. Such information may show important heredity patterns.

4. Patient's own complaint: symptoms, nature of pains and duration, exact, brief account of onset, any self-treatment the patient gave himself, report of other medical treatment he may have secured previously for the same condition, and his opinions about possible causes for his troubles.

5. Reports of physical examinations and laboratory and x-ray findings. Special forms for recording findings on physical examinations are available, and reports of other tests, often recorded on various colored slips should be attached to personal histories. This type of information varies with specialty.

6. Diagnosis: physician's evaluation, based on all information and examination findings.

7. Treatment prescribed and results obtained: suggested treatment, instructions to patient regarding follow-up treatment within a specific period of time, information on patient's progress after each visit, any changes in therapy or medication, and patient's own report about his condition, as well as date of discharge. This information is particularly important in the event of malpractice actions.

Medical records should also carry information about advice or reports given by telephone and notations should always be made during house calls which can be transferred later to the office record.

A daily procedure for record-keeping should be established early in a doctor's practice. Experience has proved that it is best to separate medical and financial records kept on each patient. Although it may appear to be simpler to record both kinds of information on one card to save the extra handling the possibilities of losing records, and the added inconvenience when the doctor and his aide compete for it at billing time are factors against a one-card system. Furthermore, the confidential medical record should not be exposed to individuals who some day may be examining the doctor's accounts.

Medical records should be filed where they are easily accessible, with all information about each patient organized in an individual folder carrying his or her name. Some physicians microfilm medical records for easier storage. It is advisable to investigate and compare the cost of standard filing cabinets of fireproof design.

Filing space should be considered in terms of estimated practice growth over a period of approximately 10 years. It is wise to tighten up the filing system periodically by weeding out "dead" material and storing it elsewhere.

Files should be placed out of the reach of patients' eyes. Lack of privacy is one disadvantage to low-cost, space-saving, open shelf filing in which envelopes of case histories are stacked upright or flat on cabinet tiers. Some office equipment manufacturers, however, offer such cabinets with shields for security. Sometimes it is desirable to use a numerical system with patients' names coded to assure files remain confidential. This is especially important when files must be located in the reception room.

Medical records belong to the physician, not the patient. They are his own notes. Such information or laboratory reports should be transferred only to doctors to whom patients are referred. Some physicians, however, give patients copies of certain records so that they can maintain a personal health record. This is done to encourage continuous attention to good health. The A. M. A. now provides a family health record booklet and a health identification card free of charge in quantity to physicians for their patients.

Laboratory and Other Diagnostic Services

Early in his practice, the new physician will want to establish contact with a reputable laboratory and with other agencies which provide necessary allied medical services needed by his patients. He also should find out as much as possible about the various medical facilities offered in his community, since these services, along with laboratory services, are an integral part of providing good medical service today. Once again, the county medical society can guide him in making the selection of proper, recognized facilities and securing information about services available locally.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

A Study of the Effects of Type A (Asian Strain) Influenza on the Cardiovascular System of Man. J. Walsh, G. E. Burch, A. White and others. Ann. Int. Med. 49:502-528 (Sept.) 1958 [Lancaster, Pa.].

The authors report on 12 male and 22 female patients, between the ages of 12 and 70 years, who were admitted to the Charity Hospital of Louisiana, in New Orleans, during the height of the epidemic of Asian influenza in July and August, 1957, and in whom the diagnosis of Asian influenza was readily established on the basis of clinical data alone. Laboratory confirmation was also obtained in 30 of the 34 patients. The 34 patients were divided into 2 groups. The first group consisted of 30 patients with typical influenza uncomplicated by clinically evident cardiovascular disturbances. The second group consisted of 4 patients with influenza complicated by clinically significant cardiovascular disturbances.

In 26 of the 30 patients without clinically significant cardiovascular complications, specific diagnostic tests, such as roentgenologic examination, hematological studies, bacterial agglutination tests, hepatic and renal function tests, lumbar puncture, determinations of serum enzymes, fluid and electrolyte studies on urine specimens, and bronchoscopic examination, substantiated the diagnosis, with the usual reservations concerning the diagnosis of viral diseases. At the height of the illness 23 (about 75%) of the 30 patients had digital vasoconstriction as well as abnormalities of the T wave in the standard electrocardiogram and of the QRSsÊ-loop in the spatial vectorcardiogram. These changes usually disappeared with convalescence.

Of the 4 patients with clinically significant cardiovascular complications of Asian influenza, 2 had rheumatic mitral stenosis. Severe infection in a patient with mitral stenosis and sufficient impairment of cardiac reserve or a critically reduced mitral orifice can produce cardiac insufficiency, and that was probably true in one of these patients. Dyspnea and orthopnea which occurred in the second patient suggested congestive heart failure, but they subsided with bed rest, restricted intake of salt, and administration of mercurial diuretics. The third patient, a pregnant woman, almost died within 24 hours of the appearance of the first symptoms of influenza. At the height of her illness she appeared to have acute pulmonary edema. Energetic therapy was effective, and no residual damage was observed. The fourth patient had a severe attack of acute rheumatic pancarditis, complicated by congestive heart failure. This attack may have represented reactivation of rheumatic fever by an unconfirmed streptococcic infection complicating influenza, or smoldering rheumatic activity that manifested itself as a result of the influenzal infection. The influenzal infection seemed to be of considerable importance in producing the cardiac manifestations.

The Syndrome of the Suspended Heart. B. A. Bradlow and M. M. Zion. Lancet 2:501-503 (Sept. 6) 1958 [London].

The occasional finding of abnormal electrocardiograms in patients without manifest cardiac disease may cause much difficulty, since without autopsy evidence of a strictly normal myocardium one cannot state that the electrocardiographic disturbance is not associated with heart disease. In 1957 Evans and Lloyd-Thomas, under the title of "the syndrome of the suspended heart," presented evidence of the association of certain specific electrocardiographic "abnormalities" with a particular radiologic configuration of the heart. The authors present 3 further cases of the "syndrome of the suspended heart." One patient was a 12-year-old girl; the second was a 24-year-old woman; and the third was a 41-year-old man.

The electrocardiograms of these patients showed abnormal S-T segments and T waves, suggesting infarction of the lateral and posteroinferior portions of the left ventricle, or of left ventricular strain without abnormal voltages. Roentgenologic examination showed a heart that, during deep inspiration, appeared to be suspended between the vascular pedicle above and the inferior vena cava below. If the electrocardiograms discussed by Evans and Lloyd-Thomas were normal and associated with a peculiar stance of the heart within the thorax, it might be expected that the changes might be found even in children, as was the case in 1 of the 3

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1949 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

patients presented. The true incidence of this syndrome in a population cannot be known without mass surveys, but recognition of the benign nature of the electrocardiographic findings is important for the sake of reassurance of the patient and for the question of insurance. Case 2 indicates that the degree of electrocardiographic "abnormality" may be considerable.

Brucellosis and Heart Disease: III. Chronic Valvular Heart Disease Following Nonfatal Brucellosis. T. M. Peery and J. M. Evans. Ann. Int. Med. 49:568-579 (Sept.) 1958 [Lancaster, Pa.]

Having noted the frequency and chronic nature of endocarditis of the aortic valve in patients with fatal brucellosis, the authors searched for evidence that similar lesions may occur in patients who survive their infection. They report on 5 men and 5 women in whom a clinical diagnosis of brucellosis was made at the average age of 40.7 years and a diagnosis of heart disease was established at the average age of 51.5 years. In some of the 10 patients the diagnosis of brucellosis was based on serologic data; in others the evidence was circumstantial; in none was there a record of positive culture of Brucella organisms. By investigating those presenting with evidence of calcific aortic stenosis, 4 of the 10 patients were detected in whom an infection diagnosed as brucellosis preceded the recognition of valvular heart disease. Conversely, by studying those in whom a diagnosis of brucellosis had been made previously, chronic valvular heart disease was uncovered in the remaining 6 patients. The aortic valve was affected in 9 of these 10 patients. Six patients died at the average age of 59.5 years, and the remaining 4 are believed to be alive. The cases of these patients show that endocarditis due to brucellosis is not necessarily fatal during the phase of active infection, but has a natural tendency to heal. They provide the missing link in the chain of evidence which connects brucellar endocarditis with calcific aortic stenosis.

Treatment of Tuberculosis of Cervical Lymph Nodes. P. C. Schmid. München. med. Wchnschr. 100:1279-1285 (Aug. 29) 1958 (In German) [Munich].

Selection of the proper treatment in patients with tuberculosis of the cervical lymph nodes depends on differentiation between the primary lymphogenous and the secondary hematogenous form of the disease. Treatment by the conservative method may be effective only in the early stage of the disease in the absence of caseation, or with slight caseation. Fistulas will form sooner or later in nodes with lymphomas, a size larger than a cherry, in which caseous necrosis has occurred. Lymph nodes, in which the tuberculous process may have reached a quiescent stage as the result of copious calcium deposits, may again become active and progressive, even after many years. In patients with this type of lesions, the radical removal of the infected lymph nodes, combined with prophylactic administration of antibiotics, preoperative treatment with antiphlogistic and antibacterial agents, and postoperative treatment with tuberculostatic drugs, is the method of choice. The treatment of patients with secondary hematogenous tuberculosis of the cervical lymph nodes depends on the underlying disease, which is usually localized in the lung, and therapy generally consists of the administration of chemobiotic agents. Tonsillectomy is indicated only in patients in whom the tonsils have been altered by chronic inflammation. Tonsillectomy should be carried out before the removal of the lymph nodes in patients with simple lymphomas, and it should be performed after the removal in patients with lymph nodes which are no longer firm and in which abscess formation has occurred. Roentgenotherapy should be considered merely as a complementary measure to reduce perifocal inflammation in small and simple lymphomas, and to prepare the patient for surgical treatment. Many workers believe that roentgenotherapy has become unnecessary since the advent of chemobiotic therapy.

Emphysema and the Lungs of the Aged: A Clinical Study: Preliminary Report. E. Mayer, C. Blazsik and I. Rappaport. Dis. Chest 34:247-256 (Sept.) 1958 [Chicago].

This study is an analysis of the prevalence and the distinguishing features of emphysema in the aged. It is in progress at the Frances Schervier Home and Hospital in New York. Of 420 men and women residents, the majority (88%) are admitted to the home in so-called normal health for their age. A minority (12%) are admitted as patients to the hospital division. Eighteen patients with pulmonary emphysema were found, of whom all but 3 were men, emphysema being predominantly a disease of men regardless of age. In contrast to this, women showed a tendency toward changes in the lungs and chest due to aging, namely, "senile lung," which, however, is not a clinical entity. Older persons with so-called senile lungs have practically no symptoms or signs of pulmonary disease. Their lungs are quite efficient within the increasingly restricted range of activity which naturally goes with progressive aging. In the series studied the diagnosis of senile lung was made only in the absence of symptoms and signs pertaining to obstructed breathing and hyperinflated lungs. Preliminary study of emphysema in the aged gave support to the validity of the concept of senile lung versus senile emphysema. Aging is associated with changes which result in the senile lung. These changes became clinically demonstrable mostly after age 80 and predominantly in women. Among older persons who had led a life of vigorous activity, especially men, senile lung changes were delayed or absent. Atrophy through disuse probably plays a role in the changes of the senile lung.

The term "senile emphysema," appears to be a misnomer. Emphysema presents the same features in the aged as in the young. In older emphysematous persons, the clinical signs and symptoms of obstructive breathing are present, and the thorax is overdistended. In the truly senile state, the chest and lungs show loss of structure and contraction in volume, but the functions appear sufficient for older persons with reduced activities. Senile lung changes may predispose to a late and rapid onset of emphysema under such pathological conditions as congestive failure or bronchopulmonary infections, which tend to increase the functional burden upon the heart and lungs.

Subacute Hepatic Necrosis and Postnecrotic Cirrhosis Due to Anicteric Infections with the Hepatitis Virus. G. Klatskin. Am. J. Med. 25:333-358 (Sept.) 1958 [New York].

The author reports on 8 women, between the ages of 42 and 66 years, and 1 34-year-old man who were selected from a group of 69 patients with subacute hepatic necrosis and/or postnecrotic cirrhosis and in whom the disease appeared to have its inception in an attack of anicteric viral hepatitis. Biopsy specimens were obtained from each of the 9 patients sufficiently early in the course of the disease to show the characteristic histological features of viral hepatitis. With one exception, all the patients were middle-aged or elderly women. Characteristically, the onset of the disease was relatively abrupt, with nonspecific constitutional and gastrointestinal complaints, but was followed within a period ranging from 2 to 18 months by the appearance of frank signs of chronic liver disease. Jaundice occurred late in 8 of the 9 patients, becoming evident within 3 to 55 months from the onset. Often it was accompanied by dark urine, light stools, pruritus, and markedly elevated serum alkaline phosphatase level, features that frequently were misinterpreted as evidence of extrahepatic biliary obstruction. In addition to the elevated serum alkaline phosphatase level, marked serum globulin concentration and high levels of thymol turbidity were helpful diagnostic clues. The disease tended to run an intermittently progressive course that was little affected by dietary measures and rest in bed and that terminated fatally in 5 of the 9 patients.

Women predominated not only among these patients but also among those with an acute or insidious onset of the disease without jaundice whose cases were reported by other workers; it shows that females at all ages are peculiarly susceptible to the anicteric form of viral hepatitis that produces subacute hepatic necrosis and postnecrotic cirrhosis. Anicteric infections by the hepatitis virus, which are readily overlooked or misinterpreted, may be responsible for many cases of otherwise unexplained cirrhosis and particularly those of the classic postnecrotic variety that occur in women.

Needle Biopsy of the Liver: Comparison of Initial Clinical and Histological Diagnoses, with a Note on Postbiopsy Mortality in Patients with Metastatic Neoplasm. C. J. Fisher and W. W. Faloon. Am. J. Med. 25:368-373 (Sept.) 1958 [New York].

The authors report on 341 patients on whom 408 needle biopsies of the liver were performed between 1950 and 1957. The results of the biopsy were of positive diagnostic significance in 226 patients, and in the remaining 115 they were either normal or revealed nonspecific changes. The initial clinical diagnosis was proved correct in 201 patients. In 26 patients, the biopsy revealed fatty metamorphosis when the clinical impression was that of cirrhosis; in these patients the clinical diagnosis cannot be considered to be in gross error. However, in the remaining 114 patients (33.4%) the clinical impression was subsequently changed by the biopsy. In 12 patients extrahepatic biliary obstruction was suspected clinically but was not confirmed on biopsy. In an additional 8 patients biopsy revealed extrahepatic obstruction which was not suspected clinically. In these patients the biopsy was of great aid in determining the need for surgery. In 30 patients metastatic carcinoma was clinically diagnosed but not found at biopsy, while in 14 patients biopsy revealed metastatic carcinoma which was not clinically suspected; thus, in 44 patients the prognosis was altered due to the fact that an unsuspected malignancy was found or that an expected malignancy was not found. In the remaining 50 patients neither the therapy nor the prognosis was greatly altered by the biopsy findings, although the histological interpretation was not the same as the clinical diagnosis. The histological diagnosis as established by needle biopsy was proved by laparotomy or autopsy to be erroneous in 8 patients. Errors in diagnosis probably occurred in 3 additional patients as revealed by the cytological study of ascitic fluid and sputum.

Biopsies were not performed on patients with a known hemorrhagic disorder or severe anemia. Despite these precautions death occurred in association with hemorrhage in 5 patients, representing a mortality rate of 1.5%. Four of these patients had metastatic carcinoma of the liver, which was found in biopsy specimens. These 4 patients belonged to a group of 33 patients with metastatic carcinoma who underwent biopsy. Thus, the mortality rate in the presence of metastatic carcinoma was 12%. These data suggest that percutaneous needle biopsy is potentially dangerous in patients with suspected malignant disease of the liver. Surgical biopsy with the aid of local anesthesia in such patients may be a preferable procedure, having the advantages of adequate visualization of the liver and thereby reducing the number of false-negative results as well as decreasing the incidence of uncontrolled hemorrhage.

Alcohol Sensitivity in Hodgkin's Disease (Report of Two Cases). D. N. Tweeddale, J. B. Whelan and F. L. Browning. Ohio M. J. 54:1165-1167 (Sept.) 1958 [Columbus].

A 50-year-old woman first noticed enlarged right cervical lymph nodes in September, 1954. These were painless and seemed at times to disappear. In August, 1955, she had an acute flare-up of inflammatory rheumatism, which subsided under treatment. After this, the enlarged cervical nodes became barely palpable. She was seen again in February, 1956, with a right-sided lobar pneumonia. At this time the cervical nodes were again enlarged, but after recovery from the pneumonia they decreased in size. Four months later, when the cervical nodes became enlarged again, biopsy revealed a proliferative, inflammatory, glandular hyperplasia. The patient began to lose weight, became short of breath on the least exertion, had dizzy spells and a very rapid pulse, and had no appetite or pep. At this time she noticed that, whenever she imbibed alcohol, there occurred pain in the back that radiated into the abdomen. It was so severe that she voluntarily abstained from alcohol. The pain commenced about 5 or 10 minutes after alcohol ingestion. It started as a dull ache in the lower part of the back and increased in intensity until it girdled the abdomen. This lasted about 1 or 2 hours and then gradually diminished. About one week before the patient was admitted to the hospital, she experienced the same reaction after a second dram dose of elixir of butabarbital (Butisol) sodium. She was rehospitalized in January, 1958, and a diagnosis of Hodgkin's paragranuloma was rendered. She was then given a course of deep x-ray therapy to cervical and retroperitoneal lymph nodes, after which all enlarged and palpable nodes practically disappeared. About 10 days after therapy she was encouraged to try a martini, which she did, with none of the aforementioned symptoms.

The second patient presented was a 27-year-old woman, who consulted her physician because of difficulty in swallowing, pain under the left shoulder blade after the ingestion of alcohol, and enlargement of the neck. Her symptoms had been present for 3 months. She stated that severe, sharp pain beneath the scapula commenced about 10 minutes after alcohol ingestion and lasted for 2 or 3 hours. Biopsy of one of the nodes revealed a typical Hodgkin's granuloma.

The authors briefly review the literature on alcohol sensitivity in Hodgkin's disease, pointing out that the commonest manifestation of alcohol-induced sensitivity in Hodgkin's disease is pain; however, generalized pruritus, cough, a sense of suffocation or oppression in the chest, increase in size of nodes and fever, and a generalized feeling of ill health have also been noted. The importance of further investigation of a patient who develops pain after alcohol consumption is stressed. The syndrome may be the earliest clinical manifestation of Hodgkin's disease. The possible value of alcohol sensitivity as a guide to therapy should be considered.

Simultaneous Occurrence of Moderate Hemophilia and Thrombopathy in One Family. S. Van Creveld, C. Everts-Coster and H. A. Veder. Nederl. tijdschr. geneesk. 102:1493-1496 (Aug. 2) 1958 (In Dutch) [Amsterdam].

The authors studied a family in which a form of moderate hemophilia occurred. With regard to the hereditary transmission, of the disease, however, this form differed from that of classical hemophilia. When a man from this family married a woman from a family in which some of the members had constitutional thrombopathy, the result was a sibship with the characteristics of both these hemorrhagic disorders.

Long-Term Use of Prednisone (Meticorten) in Generalized Cases of Lupus Erythematosus, Scleroderma and Neurodermatitis Disseminata. B. Kanee and J. Mallek. Canad. M. A. J. 79:468-472 (Sept. 15) 1958 [Toronto].

Since March, 1955, the authors had the opportunity for a close clinical and laboratory study of prednisone (Meticorten) in 3 disabling dermatomedical conditions. The purpose of their study was to determine: (1) the feasibility and efficacy of long-term therapy with prednisone in the following chronic diseases, lupus erythematosus disseminatus (systemic), generalized scleroderma (systemic), and generalized neurodermatitis disseminata (atopic eczema); and (2) the risks involved in such long-term therapy. The histories of 3 patients are presented; these patients have been on continuous maintenance therapy with prednisone, in dosages varying from 10 to 40 mg. daily, for a period of 2½ years.

It was found that long-term therapy with prednisone is feasible and justifiable in the aforementioned seriously disabling diseases. One of the major risks of long-term steroid therapy is a lowering of resistance to bacterial infections, particularly Staphylococcus pyogenes var. aureus. When acute infection supervenes, it is important to increase the dosage of corticosteroids immediately and to cover with specific antibiotics. Corticotropin (ACTH) should not be substituted during times of increased stress. One patient with systemic lupus erythematosus disseminatus on long-term prednisone therapy is showing a weight loss which may be due to a catabolic effect of the hormone. No disturbance of serum electrolytes, blood sugar, cholesterol, nonprotein nitrogen, or blood pressure has followed the long-term prednisone therapy in the dosage used.

Amyloidosis and Collagen Disease. G. Teilum. Nord. med. 60:1137-1141 (Aug. 7) 1958 (In Danish) [Stockholm].

The morphologic and clinical relationships among amyloidosis, paramyloidosis, and the collagen diseases are discussed. The diseases designated as collagen diseases are, in addition to chronic polyarthritis and rheumatic fever, 5 less frequent diseases: lupus erythematosus disseminatus, periarteritis nodosa, dermatomyositis, generalized scleroderma, and thrombotic thrombocytopenic purpura, to which paramyloidosis is now added. Common clinical-pathological features have often been found in different types of collagen disease; variants and subtypes have been described. There is no wholly clear limitation between the concept "collagen disease" and other mesenchymal diseases, as, for example, Wegener's allergic granulomatosis and allergic angiitis. Other mesenchymal diseases, mainly or exclusively localized to the reticuloendothelial system, though not usually included in the collagen disease group, will show features in common with these. Amyloid development is a direct result of a dysfunctional phase in the protein synthesis of mesenchymal cells, presumably related to disturbance in some enzyme system. Substances such as cortisone, corticotropin, and mustard gas in experimental biopsy studies on changes in the spleen, were found to promote amyloid development in the course of a few days.

SURGERY

Glioblastoma Multiforme: Review of 219 Cases with Regard to Natural History, Pathology, Diagnostic Methods, and Treatment. S. A. Frankel and W. J. German. J. Neurosurg. 15:489-503 (Sept.) 1958 [Springfield, Ill.].

The authors report on 127 male (58%) and 92 female patients (42%), between the ages of 12 and 73 years, with glioblastoma multiforme who were admitted to the New Haven (Conn.) Hospital between 1924 and 1952. An abrupt onset, simulating a vascular accident, occurred in 8 of the 219 patients; in 2 the mode of onset was unknown; and in 209 it was gradual. Headache was the leading symptom in all 3 groups; about 33% of the patients had seizures, and in half of these it was the initial complaint. The duration of symptoms before the diagnosis was made was less than 6 months in 70% of the patients, but histories longer than 1 year were elicited in 17%. The total duration of the disease was less than 1 year in 67%; 11% of the patients lived 2 to 5 years. The duration of the disease was not related to the age or sex of the patient. There was no evidence of familial incidence or of a relationship with any other disease of the nervous system.

The cerebrospinal fluid was almost always abnormal in some respect. Lumbar puncture was done for diagnostic purposes in 122 of the 219 patients; the deaths of 2 patients were directly attributable to this procedure, while the information gained was nonspecific. Routine use of lumbar puncture is not recommended. Roentgenograms of the skull revealed various abnormalities in 59% of the patients. Electroencephalographic findings were abnormal in 93% of the patients; they made possible correct localization of the lesion in 49%. Pneumoencephalograms were obtained from only 19 patients, and the procedure caused the death of 1 patient; the lesion was localized with the aid of this procedure in only 3 patients. Ventriculograms yielded a correct localization of the lesion in 104 (77%) of 135 patients. Arteriography was performed on only 21 patients, with correct localization of the lesion in 10 (48%).

Of the 219 patients, 183 underwent surgical treatment, with an operative mortality of 18.5%. Average postoperative survival time was about 3 months. The more radical surgical procedures, including "total" removal of the tumor (complete removal of all visible tumor tissue) and lobectomy, offered the best prognosis with regard to operative mortality and survival time. Of 47 patients receiving roentgenotherapy, 21 were given a course of 2,700 to 5,900 r tumor dose, which was completed within 60 days after the surgical intervention. The percentage of survivors in this group of patients was considerably higher as compared with that in the group of patients who underwent surgery alone. The effect of all present types of treatment is to prolong the patient's life by 3 to 6 months. Long-term survivals were just as common among untreated patients as among those treated. Postoperative disability tended to be great; only 40% of the patients had slight or no disability. Sixty per cent of the patients did not obtain remission of their symptoms. Only 15% of the patients went 6 months without a recurrence. There were no cures.

Pathological examination of the surgical specimens or autopsy findings revealed a mixed picture, with no single type of cell predominating in 174 patients. The fibrillary astrocyte was the predominant cell in 15 patients, the protoplasmic astrocyte in 7, the spongioblast in 6, and the astroblast in 1. In the remaining patients the predominant cell type was not recorded. Comparison of the total duration of illness in a group of 142 patients with tumors having numerous mitotic figures with that in a group of 54 patients with tumors having rare or no mitotic figures showed almost identical survival curves for both groups; thus, the number of mitotic figures seems to bear no relationship to prognosis.

Hypophysectomy in Severe Diabetes: I. Neurosurgical Aspects. M. Javid, E. S. Gordon and T. C. Erickson. J. Neurosurg. 15:504-511 (Sept.) 1958 [Springfield, Ill.].

The authors report on 11 men and 4 women, between the ages of 19 and 61 years, with severe diabetic complications of the Kimmelstiel-Wilson type who were operated on in the department of neurosurgery of the University Hospitals in Madison, Wis., between 1954 and 1957. The duration of known diabetes mellitus in these patients varied from 9 to 29 years. These patients had severe loss of vision and varying degrees of nephropathy. Neurosurgical procedures in 10 patients consisted of a complete surgical hypophysectomy and in the remaining 5, of section of the pituitary stalk. A subfrontal approach by means of a "2-in." craniotomy on the side of the blind eye was employed in all patients. The cerebrospinal fluid was drained before opening the dura mater by a T-shaped incision, the horizontal limb of the T being placed at the center of the "2-in." trephine opening with the vertical limb at the direction of the roof of the orbit. This was found satisfactory to protect the brain, which is of great importance in these diabetic patients. The hypophysectomy was performed according to Olivecrona and Ray's techniques. Section of the pituitary stalk was performed by dividing the stalk between 2 tantalum clips immediately above the diaphragma sellae, and a piece of polyethylene film was placed over the distal end. Endotracheal anesthesia was used in all the patients.

There was a consistent and marked decrease in insulin requirement postoperatively. Average blood pressure readings were all lower than preoperatively except in one patient. There was consistent improvement in the diabetic retinopathy and return of vision in some patients. Three patients died within 2 to 8 days after the surgical intervention, and 5 patients died after discharge from the hospital within 3 to 26 months after hypophysectomy. Five of the 8 deaths resulted from severe, prolonged hypoglycemia. Of the remaining 3 patients who died, severe diabetic nephropathy and cerebral edema caused the death of the first patient, severe coronary sclerosis, pulmonary edema, and hypertensive encephalopathy were responsible for the death of the second, and bronchopneumonia and purulent tracheobronchitis were the chief causes of death in the third. Autopsy performed on 2 patients who died after section of the hypophysial stalk revealed very extensive necrosis of the anterior pituitary in one patient and only a small area of necrosis in the other. These findings may account for the observation that improvement in vision and alteration in endocrine assays in the patients who underwent section of the pituitary stalk were not parallel to the improvement observed in the patients who underwent hypophysectomy. Section of the hypophysial stalk does not appear to be the physiological equivalent of total hypophysectomy, both from the standpoint of practical therapeutic results and from physiological studies.

Hypophysectomy is not indicated as a routine therapeutic method in patients with advanced juvenile diabetes mellitus, but further studies and reevaluation are indicated. Major renal insufficiency is a contraindication to surgical treatment which should not be performed on patients who will not follow instructions concerning insulin administration and diet postoperatively. Teamwork between neurosurgeon and endocrinologist as well as careful follow-up are essential. Hypophysectomy transforms a severe diabetic condition to a mild one as far as insulin requirement is concerned, but it does not reverse permanent vascular changes that have already occurred. The results obtained in some of the surviving patients, however, have been sufficiently impressive to consider hypophysectomy as having a place in the management of selected patients with severe diabetes and intercapillary glomerulosclerosis (Kimmelstiel-Wilson's disease).

Destruction of the Hypophysis with Radioactive Colloidal Chromic Phosphate in Cancer of the Prostate. P. C. Johnson, K. M. West and B. J. Rutledge. J. Neurosurg. 15:519-527 (Sept.) 1958 [Springfield, Ill.].

The authors treated 6 men, between the ages of 59 and 66 years, with biopsy-proved carcinoma of the prostate by direct injection of radiophosphorus (P^{32}) as colloidal chromic phosphate into the hypophysis. The pituitary stalks were clipped and severed before the injection of P^{32} in 3 of the 6 patients. Five patients had undergone previous orchiectomy, with symptomatic improvement resulting in 4. All the patients required administration of narcotics for relief of pain, and each patient had become refractory to estrogen therapy before destruction of the pituitary was attempted. Three of the 6 patients died within 32 hours to 5 days after the operation. The other 3 patients survived the operation for periods ranging from 10 weeks to 1 year. The 3 survivors noted relief of pain in bones. One of these 3 showed objective evidence of remission of tumor growth. Panhypopituitarism was present in 2 of the 3 patients. In one patient this persisted until his death 10 weeks after the surgical intervention. In the other patient the hypopituitarism and diabetes insipidus produced by the procedure disappeared 6 months after surgery.

Autopsies were done on 5 patients. Of the 3 in whom the pituitary stalk had not been divided before the injection of P^{32}, 2 showed minimal histological changes in the hypophysis. In the 2 patients in whom the stalk was divided, the hypophysis was completely destroyed. These findings would suggest that division of the stalk combined with irradiation may result in more complete destruction of the pituitary body than does irradiation alone. The finding of considerable amount of P^{32} in both the spinal fluid and the blood as early as the first day after the intrapituitary injection showed that the injected material disappeared rapidly from the hypophysis. Destruction of the pituitary by irradiation is yet to be proved superior to surgical hypophysectomy.

Pulmonary Cancer Without Roentgen Findings. J. L. Hansen. Ugesk. læger 120:1037-1044 (Aug. 7) 1958 (In Danish) [Copenhagen].

In a series of 343 consecutive cases of bronchial carcinoma, there were 42 in which roentgenography showed nothing pathological. In these cases the apportionment according to sex, age, and histological type agreed with that in the total material; the history was relatively long. The symptoms were most often typically bronchial. Bronchoscopy is urged in cases with suspect bronchial symptoms of more than a few weeks' duration, also when roentgen-ray examination shows normal conditions. Repeated prescription of cough medicine without careful clinical observation is not advised. The symptoms which should awaken suspicion of bronchial cancer (also in cases with normal roentgen-ray picture) are cough or change in the usual cough, expectoration, strident respiration, together with dyspnea, and pain in the thorax. Bronchoscopy gives a positive diagnosis about equally often in early and late cases of bronchial cancer and is equally indispensable in excluding and in establishing the diagnosis of bronchial cancer. Normal roentgen-ray picture in 2 planes and normal bronchoscopy will with considerable certainty exclude the possibility of bronchial cancer.

Operative Treatment of Pulmonary Metastases and of Pulmonary Processes with Suspected Metastases. J. L. Hansen. Ugesk. læger 120:1045-1052 (Aug. 7) 1958 (In Danish) [Copenhagen].

Thirty cases of pulmonary metastases in 18 men and 12 women, mostly between 50 and 69 years of age, were analyzed. In 7 cases pulmonary resection was done, with 8 operations, as one patient was operated on bilaterally. There were no postoperative complications or deaths. Six of the patients are living without signs of recurrence from 4 to 15 months after the operation. In the same period 7 other patients with suspected pulmonary metastases were operated on and were found to have other diseases. Solitary solid pulmonary processes should generally be treated operatively, even when there is history of malignant extrathoracal tumor, provided that the primary cancer has been treated radically and there is no evidence of other metastases. Roentgenologic examination of the lungs at regular intervals is proposed for patients who have been operated on, with apparent success, for extrathoracal malignant tumors.

Should We Insist on "Radical Pneumonectomy" as a Routine Procedure in the Treatment of Carcinoma of the Lung? J. Johnson, C. K. Kirby and W. S. Blakemore. J. Thoracic Surg. 36:309-315 (Sept.) 1958 [St. Louis].

The authors point out that Allison in 1950 proposed the term "radical pneumonectomy" to describe the removal of all possible mediastinal areolar tissue, containing the lymphatics, in continuity with the lung. According to Watson, whose motion picture on radical pneumonectomy has been widely circulated, the dissection starts at the apex of the mediastinum, and all areolar tissue and lymph nodes are reflected downward as the trachea, esophagus, and other important structures, as well as the contralateral bronchus, are partially "skeletonized." The pericardium is resected with the lung and mediastinal tissues after the pulmonary vessels have been divided intrapericardially. The film implied that anyone doing less than a radical pneumonectomy for cancer of the lung might not be doing everything possible to cure his patients. The authors, at the Hospital of the University of Pennsylvania, had been removing lymph nodes in the mediastinum immediately adjacent to the hilus, going over as far as the bifurcation of the trachea, but they had resected the more distant nodes only when there seemed to be involvement of those nodes, and, therefore, they found themselves on the defensive regarding the surgical treatment of pulmonary cancer.

The authors compared the 5-year survival rate they had obtained with their "standard" resection with the 5-year survival rate obtained by those who employed radical pneumonectomy. Of 764 patients with carcinoma of the lung at the Hospital of the University of Pennsylvania, 344 were seen more than 5 years ago. Of this group, 192 (56%) were explored and 116 (34%) were subjected to pulmonary resection. The operative mortality was 7.7%. Thirty-one patients (26.7% of those subjected to resection or 9% of the total number of patients) survived 5 years or more. Radical pneumonectomy was not employed in this series. The 5-year survival so far reported after radical pneumonectomy is not significantly higher than the authors obtained with the standard-type resection. They suggest that until it can be shown that radical pneumonectomy produces superior results, the thoracic surgeon is not obligated to perform the radical operation. However, they do not wish to discourage the resection of all grossly involved tumor tissue and feel that the surgeon should make a real effort to get around the locally invasive tumor whenever possible.

Studies to date indicate that blood vessel invasion as found in the surgical specimen is of greater prognostic significance than lymph node invasion. Whereas there was only a 6% 5-year survival among those patients showing blood vessel invasion in the tumor, there was a 75% 5-year survival when blood vessel invasion was not present. This may in part account for the fact that radical pneumonectomy to date has not produced the great improvement in the 5-year survival rate which was anticipated.

Further Studies in the Surgical Management of Carcinoma of the Lung: A Further Study of the Cases Treated at the Massachusetts General Hospital from 1950 to 1957. E. D. Churchill, R. H. Sweet, J. G. Scannell and E. W. Wilkins Jr. J. Thoracic Surg. 36:301-308 (Sept.) 1958 [St. Louis].

The previous report on the surgical management of primary carcinoma of the lung at the Massachusetts General Hospital in Boston included all patients seen in the years from 1930 to 1950, with follow-up data on all resections carried out prior to January, 1948. The present study brings up to date the results of surgical management of cancer of the lung at the same hospital by adding the cases of all patients seen in the period from January, 1950, to January, 1957, with follow-up information on all resections performed before January, 1956. Complete follow-up data are available on 341 resected cases. These data show that in the recent 7-year period a greater percentage of patients with proved carcinoma of the lung have come to operation than in the earlier series (55% compared with 43%). The resectability rate has also increased (35% of proved cases compared with 25%). The 5-year cumulative survival rate for all patients undergoing resection for cancer of the lung remains approximately 28%. The 10-year cumulative survival rate for such patients is 18%.

Results in the Treatment of Bronchogenic Carcinoma: An Analysis of 1,008 Cases. T. H. Burford, S. Center, T. B. Ferguson and H. J. Spjut. J. Thoracic Surg. 36:316-328 (Sept.) 1958 [St. Louis].

The senior author and his associates at the Barnes Hospital in St. Louis observed 1,008 patients with primary bronchogenic carcinoma of the lung between 1948 and 1955, inclusive. The diagnosis was verified in 100% of the cases by microscopic section, the material being obtained by bronchoscopic biopsy, cytological study of the sputum, biopsy of metastatic implants, needle biopsy, frozen-section biopsy at the time of thoracotomy, and examination of the resected specimens. The minimum follow-up period was 1½ years and the maximum, 9½ years. The distribution as to sex, age, cell type, and site of origin did not differ significantly from that of other reported series. Surgical exploration was carried out in 60% of the patients; resection was possible in 35%. Pneumonectomy comprised 80% of the resections; lobectomy, 20%. The percentage of lobectomy cases increased from 3% in 1948 to 30% in 1955. The over-all operative mortality was 11%.

The 5-year survival rate for all patients who were followed an adequate length of time was 9%. In the selected group in whom surgical resection was possible, the 5-year survival rate was 22%. Study of the resected specimens from the 5-year survivors revealed epidermoid carcinoma to be the most prevalent cell type (77.5%), but a surprisingly high number of undifferentiated tumors (12.5%) were present. Almost half (45%) of the specimens showed lymph node involvement, and 8% had blood vessel invasion. Surgical resection could be done in only 1 of each 3 cases diagnosed. This ratio remained unchanged throughout the 8-year span. Significant increase in 5-year survivals will be possible only through an increase in the percentage of resections performed.

Clinical and Experimental Observations on 1627 Cases of Cancer of the Breast (Continuation and Conclusion). J. Lavigne. Acta chir. belg. 57:215-231 (March) 1958 (In French) [Brussels].

This concluding chapter in a study of 1,627 cases of breast cancer, with a follow-up of at least 5 years, is devoted to the problem of recurrences, with special reference to their possible causes. A 10-year follow-up period was considered appropriate for this part of the work, because, while recurrences have been reported after periods of more than 10 years—even 15 or 20 in some cases—it is quite possible that these very late recurrences really represent either second cancers or the reactivation of an overlooked islet of the original tumor. Patients followed for less than 10 years were therefore excluded from consideration, as were 89 others —30, because they did not receive standard treatment, i. e., a radical operation, either alone or followed by roentgenotherapy; 4, because they were lost sight of before the end of the 10th year; and 55, because they died of intercurrent diseases. Almost four-fifths of the remaining 859 patients (682, or 79.3%) had one or more recurrences during the 10 years they were under observation, while the other one-fifth (177) were still living at the end of 10 years without ever having had a recurrence.

Statistical analysis of the findings in the 682 patients with recurrences showed that there was no connection between the age of the patients and the appearance of the recurrent lesions. This fact, which is in harmony with the findings obtained in the earlier part of this study, warrants the conclusion that the primary tumor and its possible recurrences behave in exactly the same way. Most (85%) of the recurrences appeared in the first 5 years, and after the 8th year the percentage of recurrences became negligible. Correlation of the number of recurrences with the stage of the cancer at the start showed that 86% of the stage 3 and stage 4 tumors recurred during the first year, as against only 49% of the stage 1 tumors. The findings in these patients failed to show any relation between the average survival periods and the time at which the first recurrence became clinically apparent. It must be remembered, however, that the number of patients in certain categories, e. g., those with recurrences in later years, was small and that the exact time of appearance of a recurrence cannot always be precisely determined.

Recurrences were less frequent in patients treated with combined surgery and x-ray therapy than in patients treated with surgery alone. The type of treatment given, whether surgery alone or surgery combined with x-rays, on the other hand, had no effect on the date and rate of appearance of recurrences, the frequency of metastases and generalization, or the length of the survival period.

A separate study of 24 patients in whom recurrences took place more than 10 years after the initial treatment of the original tumor was noteworthy, first, for the small number of patients so affected, and, second, for the much greater length of the average survival period, which was 42 months in these patients, as compared with 18 to 21 months in those in whom recurrences appeared earlier. Various modern studies on the latency of cancer cells seem to show that these late recurrences are due to the effect of some unknown factor—either a direct chemical agent or a vascular modifier—which gives latent cancer cells increased mitotic power.

PEDIATRICS

Congenital Hernia of the Diaphragm in Newborn Infants. R. Neimeier. Ann. paediat. 191:87-94 (Aug.) 1958 (In German) [Basel, Switzerland].

In the course of 5 months, 4 newborn infants with congenital diaphragmatic hernia were observed in the Woman's Clinic of the University of Basel. The author believes that this high incidence was accidental, as only 28 infants with fatal congenital diaphragmatic hernia had been observed over a period of 50 years among 103,786 births. The course was similar in all 4 infants. They appeared viable and emitted 1 or 2 weak cries. After the cutting of the cord, however, increasing dyspnea rapidly led to cyanosis. The action of the auxiliary respiratory musculature increased again, as did also the pulse and respiratory frequencies, but the respiratory excursions of the involved side of the thorax were diminished, and auscultation revealed no respiratory sounds on this side. The latter sounds may eventually be displaced by intestinal peristaltic sounds.

Circulatory stimulants were ineffective in these cases. The administration of oxygen produced only temporary improvement and was incapable of preventing the increasing dyspnea and death, which in the 4 infants occurred within 40 to 125 minutes. In 3 of the infants mediastinal displacement had the effect that the heart beat was audible on the right side of the thorax. A roentgenologic survey examination, which in 2 of the infants was done only after death, corroborated the diagnosis. It revealed gas-filled intestinal loops in the involved side of the thorax and displacement of the mediastinum and trachea; in some cases, shadows of abdominal organs (liver) protruded into the thorax. In 3 cases the diagnosis was further corroborated by roentgenography with the aid of barium as contrast medium. The congenital hernia of the diaphragm was associated with other congenital defects in 3 of the 4 infants. Operative repair of the diaphragmatic hernia would become possible only if the condition were recognized early.

Postpneumonic Pseudo Air Cysts in Children. K. Schlager. Fortschr. Geb. Röntgenstrahlen. 89: 136-146 (Aug.) 1958 (In German) [Stuttgart, Germany].

The formation of cyst-like hollow spaces in the course of or after pneumonia in children seems to have increased in incidence since the introduction of modern chemotherapeutic treatment, and particularly antibiotic therapy. The terminology of the condition is somewhat confused, since it has been reported under such diverse terms as tension vesicles, valvular cyst, localized or bullous emphysema, metapneumonic emphysema, pneumotoceles, pseudocavities, ring shadows due to resorption, acquired cysts, and obstructive emphysema. The author prefers the term "postpneumonic pseudocyst," because it not only differentiates the condition from congenital pulmonary cysts but also suggests the etiology and gives the impression of a thin-walled, aerated hollow space. These postpneumonic pseudocysts develop in the pulmonary parenchyma, chiefly in infants and young children, and are characterized by considerable variation in size and by the fact that they produce no symptoms and that they generally regress spontaneously without treatment.

There is as yet no complete agreement on the pathogenesis, but the majority of investigators are of the opinion that a hollow space develops in the peripheral lung tissue as the result of a valvular stenosis in a small bronchus or bronchiolus. Presumably the increase in pressure beyond the valve-like bronchostenosis causes dilatation of the alveoli or lobuli in the form of a functional emphysema, and the inflammatory changes in the surrounding parenchyma promote the tendency to expansion. On the other hand, it is possible that hollow spaces are formed as the result of poststenotic inflation of foci of gangrenous or suppurating breakdown. There is as yet no agreement as to whether the air inflation of the pseudocyst occurs during inspiration or expiration, the more so since exploratory puncture is inadvisable because of the danger of possible complications, such as tension pneumothorax, collapse, or infection. The author regards it as most likely that air enters the poststenotic part of the lung chiefly during forced expiration, that is, during coughing.

The following factors are characteristic for postpneumonic pseudocyst: roentgenologic or anamnestic evidence of pneumonia; circular or (when large) long oval shape of the outline; a thin wall; fluctuation in size, and well-being during enlargement; and regression without treatment. The differential diagnosis is difficult and must rule out pneumonia with abscess formation, partial and tension pneumothorax, bronchiectasis, congenital pulmonary cysts, diaphragmatic hernia, tuberculous cavities, and various other lesions that may cause ring-shaped shadows. Illustrating case histories are presented of 4 children who had postpneumonic pseudocysts. They ranged in age from 5 months to 3½ years.

Congenital Deaf-Mutism, Prolonged QT Interval, Syncopal Attacks and Sudden Death. S. A. Levine and C. R. Woodworth. New England J. Med. **259:** 412-417 (Aug. 28) 1958 [Boston].

The authors report a new and a very distinct clinical entity—congenital deaf-mutism associated with functional heart disease. A young boy showed the essential peculiarities that identify the condition, such as attacks of unconsciousness; peculiar electrocardiograms, consisting of marked prolongation of the QT interval, with large T waves; sudden, early death; and no other objective evidence of organic heart disease or any other disease (except for deaf-mutism) on physical or postmortem examination. The electrocardiograms in these cases (a family in which 4 members manifested these same unusual features has recently been reported) are peculiar and unique. They are not absolutely constant from month to month, though generally the characteristic features are present. The PR interval tends to be slightly shorter and does not vary even when the ventricular complex changes. The most striking feature is the long QT interval, with large and often bifurcated T waves which may be positive, negative, or biphasic. At times the T waves resemble those seen in hyperkalemia, and at other times the tracings suggest the possibility of a disturbance in calcium metabolism or hypoparathyroidism, in spite of the fact that all electrolyte studies in such cases have been normal. Although the duration of electric ventricular systole is markedly prolonged, mechanical systole is of normal duration. Another feature of the electrocardiograms is the variability of the form of the complexes and the fact that the tracings may spontaneously revert to normal.

In the case reported, the fainting attacks experienced by the patient seemed to be related only to emotional situations in which he was frightened or told to do something that vexed him. No microscopic or gross cause of death could be found at autopsy, and in the absence of adequate cause death was presumed to have occurred as a result of sudden cardiac arrest or ventricular fibrillation. Another peculiarity of this condition is that in the few cases that have been reported death has occurred in childhood, the 3 previous patients having died at the ages of 4, 5, and 9 years and the patient in this case at the age of 13 years.

Neuroblastomas and Nephroblastomas: Clinical Study with Personal Material. S. Nordøy. Tidsskr. norske lægefor. **78:**705-709 (Aug. 1) 1958 (In Norwegian) [Oslo].

The author studied the symptoms, the clinical and roentgenologic signs, and the therapeutic results in 35 children with malignant retroperitoneal tumors admitted to the children's clinic of the Rikshospital in Oslo from 1938 to 1955. The average age on admission was 2½ years. The average duration of symptoms before admission was 9 weeks. Eleven patients had clinical or roentgenologic signs of metastases on admission. Seventeen cases were thought suitable for surgical treatment, but complete excision proved possible in only 5 cases, all of Wilms's tumor. One patient has survived 14 years after nephrectomy without irradiation treatment and another, 3½ years after preoperative irradiation and nephrectomy; in 3 cases recurrence set in after 2 months, 1 year, and 2½ years respectively. The prognosis for malignant retroperitoneal tumors in children has heretofore been considered extremely unfavorable in spite of treatment. Because of the rapid growth of these tumors, their early spread, and the absence of early characteristic symptoms, diagnosis is often made too late for reasonable hope of successful treatment.

Nephroblastomas originate from renal tissue; neuroblastomas develop from the sympathetic nerve tissue in the adrenals and along the posterior part of the abdominal wall. Differential diagnosis between the two tumor forms is difficult and often impossible. On the least suggestion of malignant disease, examination by a pediatrician and/or a roentgenologist is indicated, with hospitalization as soon as possible for active treatment if the suspicion is verified. With regard to nephroblastomas, there is general agreement that complete excision of the primary tumor is necessary for survival and that postoperative roentgen-ray treatment is necessary for improvement of the prognosis. When there are disseminated metastases, treatment can be only palliative. In the case of neuroblastomas, partial removal of the primary tumor and energetic postoperative roentgen-ray treatment give a relatively high percentage of survival, even with simultaneous liver metastases and regional lymph node metastases. With disseminated skeletal metastases, treatment can never be other than palliative. Early complete excision is the foremost aim also in this tumor form. Recovery has been seen on roentgen-ray treatment alone.

Congenital Afibrinogenemia. S. van Creveld and Liem Khe Hoo. Maandschr. kindergeneesk. 26: 227-237 (July) 1958 (In Dutch) [Leiden, The Netherlands].

The development of hematoma after trauma or prolonged bleeding during tooth eruption are the chief manifestations of congenital afibrinogenemia, whereas nasal and gastrointestinal hemorrhages are rare, and petechiae are never observed. This last aspect is probably due to the fact that the function of the blood platelets is normal. Congenital hypofibrinogenemia or afibrinogenemia can be temporary or permanent. The permanent form has been ascribed to hereditary factors. The female infant, whose history is presented, was the first child of healthy parents who were not related and whose family histories were free from hemorrhagic diathesis. Subcutaneous bleeding on the occiput and the neck of the infant was observed 24 hours after birth. Blood transfusion through the umbilical vein arrested this hemorrhage, and the hematoma disappeared. Hemorrhage from the umbilicus on the 8th day necessitated suture of the umbilical wound. It was found that the process of blood coagulation was impaired, but the child was discharged from the hospital 30 days after birth and remained free from severe hemorrhages to the end of the first year of life, when a blow caused a hemorrhage on the dorsum of the foot.

At this time various methods of examination failed to detect fibrinogen in the infant's blood. The authors emphasize that in the blood of such a patient the antihemophilic factor is present in normal quantities notwithstanding the absence of fibrinogen. There exists, however, an increased instability of the antihemophilic factor in the blood and an increased prothrombin consumption. There also exists a relationship between the fibrinogen content of the plasma and the prothrombin time, determined according to Quick's method. Transfusions of blood, plasma, or fibrinogen are promptly effective against the hemorrhagic diathesis of afibrinogenemia, but the effect is temporary only.

Hypovitaminosis C and Osteomyelitis in Childhood. R. Della Casa. Riforma med. 72:788-791 (July 12) 1958 (In Italian) [Naples].

A comparative investigation designed to determine the possible etiological correlation between the state of hypovitaminosis C and osteomyelitis was undertaken among 60 hospitalized children, aged between several months and 11 years. They were divided into 2 equal groups. The children in one group had osteomyelitis and those in the other group had disorders of the respiratory tract associated with fever, most of which were of the bronchopulmonary type. Ascorbic acid blood values among the children with osteomyelitis were very low in 11 children (up to 0.6%), fair in 11 (up to 1.12%), average in 6 (up to 1.5%), and saturated in none. History of these patients revealed that they had not previously received vitamin C and that their diet had been poor. This study was made in 5 children during the first week of the disease, in 6 children during the second week of the disease, and in the remainder after more than 2 weeks of the disease.

Ascorbic acid blood levels in 30 children with disorders of the respiratory tract varied within the physiological limits; these levels were fair in 14 children (up to 1.10%), average in 15 (up to 1.60%), and saturated in 1 child (over 1.60%). Vascular fragility values were high among most of the children with osteomyelitis but were within normal limits among those with respiratory disorders. Skin infections due to common pyogenic micro-organisms were frequent among the children with osteomyelitis. Blood examination revealed the presence of the same strain of pyogenic micro-organisms in the skin infections as in the osteomyelitic foci in 12 children. The author believes that a state of primary hypovitaminosis C was present in children who had osteomyelitis.

Hormone Excretion in Precocious Puberty in Girls. R. D. Bulbrook, F. C. Greenwood and A. H. Snaith. Arch. Dis. Childhood 33:295-300 (Aug.) 1958 [London].

The authors made determinations of estrogen, 17-ketosteroid, and gonadotropin in the urine collected from 11 girls, between the ages of 7 months and nearly 11 years, with precocious or early puberty. The vaginal smears of these 11 girls were likewise examined. Determinations of estrogen in the urine collected from 15 normal girls, between the ages of 3 and 10 years, were also carried out. Nine of the 11 girls with precocious or early puberty were excreting amounts of estrogen above 1 mcg. per 24 hours. In 7 of these girls positive vaginal smears were correlated with the finding of estrogen in the urine, and in 2 girls negative vaginal smears were correlated with the absence of estrogen in the urine. In one patient a negative smear was obtained in conjunction with 1.8 mcg. of estriol in the urine, while in another patient a positive vaginal smear was obtained but no estrogen was detected in the urine. The 17-ketosteroid excretion in 24-hour urine specimens varied from 0.7 to 2.5 mcg. as contratested with 0.47 ± 0.16 to 2.3 ± 0.85 mcg. in the specimens obtained from the normal girls. Of the 15 normal girls, estrogen was detected in the urine of only a 7-year-old girl who excreted 2.9 mcg. per 24 hours. Among other girls over 11 years of age who had breast development and pubic hair, but who had not menstruated, measurable amounts of estrogen varying from 2.9 to 7.1 mcg. were found in 24-hour specimens of urine.

While the 17-ketosteroid levels in the urine of girls with precocious or early puberty have been at the upper range of normal values and the estrogen levels have been above contratest levels, the results of these estimations are not diagnostic of precocious puberty, since completely normal values are not incompatible with the diagnosis. However, the obtained results are of value in distinguishing true precocious puberty from precocity due to pathological conditions, involving the gonads or the adrenals, and from nonhormonal vulval bleeding.

Exchange Transfusion for Acute Poisoning in Children. O. C. Bruton. U. S. Armed Forces M. J. 9:1128-1131 (Aug.) 1958 [Washington, D. C.].

Because dialysis of almost any nature is technically difficult and not available to most hospitals, exchange transfusion has been found to be effective and without undue hazard in the newborn period to prevent or remove dangerous amounts of circulating indirect bilirubin. Exchange transfusion may also be employed to remove dangerous amounts of other circulating substances, such as poisons, encountered in older children. Three among 142 children admitted to Tripler Army Hospital in Honolulu, T. H., were treated with exchange transfusion after ingestion and poisoning with large amounts of either Nembutal (brand of pentobarbital sodium), Pyridium (brand of phenylazo-diamino-pyridine hydrochloride), or aspirin. No deaths occurred. Exchange transfusion in selected cases of acute poisoning is effective and without hazard, but it must be started as soon as possible after evaluation of the patient and the circumstances surrounding ingestion of the poison.

Accidents in Childhood: A Survey of 150 Cases in Private Paediatric Practice. R. S. Fowler. Canad. M. A. J. 79:241-246 (Aug. 15) 1958 [Toronto].

The author reports on 138 children, seen in his private practice, who had 150 accidents about which he was consulted. Of the 138 children, 129 had 1 accident each, 6 had 2 accidents, and 3 had 3 accidents. Ninety-one accidents (61%) occurred among boys, and 59 (39%) among girls. Boys over 3 years of age were about 2½ times more frequently involved in accidents than girls. One hundred three accidents occurred among children of preschoo age, and 47 accidents among those between the ages of 6 and 13 years. Eighty-two accidents occurred inside the home and 13 in the adjacent yard as compared with 55 which occurred outside these premises. Of the 150 accidents, 105 (70%) were du to physical trauma, 22 (15%) to foreign bodies and material, 17 (11%) to poisoning, and 6 (4%) to burns Falls were the main cause of physical trauma, with falls from a height usually occurring among younger children and falls on the level among olde children. Foreign bodies seldom had serious consequences, but the ingestion of them seemed to b a manifestation of the same urges that cause children to ingest chemicals or drugs. These finding emphasize the principle that infants must be completely protected from hazards and that older children must be taught good safety habits.

UROLOGY

The Urinary Excretion of Calcium and Inorganic Phosphate in 344 Patients with Calcium Stone of Renal Origin. A. Hodgkinson and L. N. Pyrah. Brit. J. Surg. 46:10-18 (July) 1958 [Bristol, England].

The authors studied the urinary excretion of calcium and inorganic phosphate in 220 men and 124 women with calcium stone of renal origin, who were seen at the General Infirmary in Leeds, England, and in 132 normal men and 126 normal women. It is permissible to compare the distribution of urine calcium and inorganic phosphate values for normal adults with the distribution for a group of adult patients with stone, since the effect of normal variations in the intake of calcium and phosphorus on the excretion of calcium and inorganic phosphate in the urine is small compared with the effect of physiological variations among individuals. The normal range for the urinary excretion of calcium by adults on normal diet was found to be about 100 to 300 mg. per day for men and 100 to 250 mg. per day for women. The corresponding ranges for the urinary excretion of inorganic phosphate were 500 to 1,500 mg. per day for men and 500 to 900 mg. per day for women. The urinary excretion of inorganic phosphate by patients with stone did not differ appreciably from that of normal persons, but the urinary excretion of calcium was depressed, and there was appreciable impairment of renal function. It was found that about 11% of the 344 patients with stone had evidence of poor renal function. After omitting these patients, it was found that 59% of the remaining patients had average urine calcium values greater than 200 mg. per day, as compared with 26% of the normal adults.

The incidence of high urine calcium values was greater in normal men than in normal women. In patients with stone, the incidence of stone and of high urine calcium values was greater in men than in women. The incidence of high urine calcium values in patients with a history of recumbency at some time in the past, a family history of stone, or an anatomic abnormality of the kidneys was about the same as that in patients with stone as a whole. Parathyroid adenoma or hypertrophy was found at exploration of the neck in 8 (2.3%) of the 344 patients; these 8 patients had average serum calcium values of 11.2 mg. per 100 cc. or higher. All except one of these patients had high urine calcium values, the exception being a woman with poor renal function. The average serum calcium values in the 344 patients varied between 7.6 and more than 11.6 mg. per 100 cc. Eighty-five patients had average serum calcium values of 10.6 mg. per 100 cc. or higher, but only 31 of these patients had urine calcium values in excess of 300 mg. per day for men and 250 mg. per day for women. The remainder had normal or low urine calcium values. Patients with average serum calcium values greater than 10.5 mg. per 100 cc., who also have high urine calcium values or poor renal function, should be kept under observation with a view to subsequent neck exploration.

Analysis of stones was carried out in 136 patients; there appeared to be a definite relationship between the incidence of high urine calcium values and the structure and chemical composition of stones. A high urinary excretion of calcium does not, by itself, result in stone formation, but it increases the chance that stone formation will occur, and it appears to influence the type of stone formed.

Nephrogenous Polycythaemia. J. Forssell. Acta med. scandinav. **161**:169-179 (No. 3) 1958 (In English) [Stockholm].

Twenty-eight cases of nephropathy associated with secondary polycythemia are reported by the author. Hypernephroma was present in 22 cases, polycystic kidney in 4, fibromyxoma of the kidney in 1, and unilateral hydronephrosis in 1. Hematuria was found to be an important initial symptom, being observed in almost all cases of hypernephroma and in 1 case of polycystic kidney. Nephrectomy was performed in 13 cases, and with the exception of 1 case, where polycythemia did not develop until after the operation, it disappeared after removal of the affected kidney.

The role of the kidney in the metabolism of hemopoiesis is considered important in that removal of a tumor of the kidney, or of a whole affected kidney, sometimes results in the disappearance of polycythemia. Other investigators have found that this factor, which regulates erythropoiesis, is stimulated by various forms of anoxia and is responsible for the polycythemia known to occur at high altitudes. It has been observed in the umbilical cord in newborn infants, in congestive heart failure, after venous stasis in an extremity, in posthemorrhagic anemia, in erythroblastosis fetalis, and in Cooley's and sickle-cell anemia. Still other investigators have established that the hypophysis is the source of this factor or, at least, is closely associated with erythropoiesis. Jakobsen and coworkers, by removing almost every organ in turn, were able to show that the kidneys were the only possible source of erythropoietin production. A rise in the erythropoietin titer, variously caused, failed to occur after bilateral nephrectomy but not after ligation of both ureters. Should these theories prevail, there is still nothing to obviate the possibility that the nephrectomy performed in some of the present cases influenced the erythropoietin metabolism.

The Significance of Vesicoureteral Reflux in Children. V. A. Politano. North Carolina M. J. **19**:297-304 (Aug.) 1958 [Winston-Salem].

The author reports on 2 girls and 2 boys, aged 4, 6, and 12 years, respectively, with a history of persistent or recurrent urologic difficulties of from 5 months' to 2 years' duration. The diagnosis was established by cystography, either with exposure during micturition or with delayed exposure. Cystourethrograms during micturition have been more informative than cystograms with delayed exposure; however, in the very young child cystograms with delayed exposure will have to be sufficient.

The diagnosis in a 4-year-old girl was ectopic ureteral insertion with ureteral reflux and pyelonephritis on the left side. Treatment consisted of reimplantation of the left ureter by creation of a submucosal tunnel. This successfully corrected the vesicoureteral reflux. Postoperative intravenous pyelograms showed good excretion from the left kidney without evidence of obstruction. The child has remained asymptomatic for a period of 20 months. Microscopic examination of the urine was negative, and cultures have been sterile.

The 12-year-old boy was admitted for bilateral hydroureters and hydronephrosis. There was a 2-year history of enuresis. Preoperative diagnosis was bilateral vesicoureteral reflux. Some neurogenic disturbance of the bladder was strongly suspected as well. Treatment by bilateral reimplantation of the ureters with the use of a submucosal tunnel resulted in marked improvement of the preexisting hydronephrosis and hydroureters and in correcting the vesicoureteral reflux. During a year's observation 6 to 8 white blood cells were observed in the urine. The patient has, on occasions, shown some bacilli, but he has had no further recurrences of fever and chills.

In the 6-year-old boy the diagnosis was contracture of the vesical neck with median bar formation, bilateral reflux, and reduplication of the left ureter. The operative treatment consisted of excision of the double ureters on the left, reimplantation of the right ureter with the use of a submucosal tunnel, and a Bradford-Young repair of the vesical outlet. This succeeded in correcting the vesicoureteral reflux on the right side. Postoperative intravenous pyelograms showed good function in the remaining kidney and a normal excretory pyelogram. The urine has remained normal, and cultures have been sterile. The child has remained completely asymptomatic during the 6-month period that he has been observed.

Another 4-year-old girl was admitted with a history of recurrent abdominal pain, frequency of urination, intermittent fever, and malaise of a year's duration. She had been treated intermittently for cystitis and pyelonephritis with chemotherapy and antibiotics. Vesicoureteral reflux on the right side was diagnosed preoperatively. The creation of a submucosal tunnel has been most successful in correcting the reflux on the right, but reflux has persisted on the left side. Postoperative intravenous pyelograms demonstrated a normal upper urinary tract. The child has remained completely asymptomatic, her urine being normal without medication.

Vesicoureteral reflux should always be considered abnormal. Every child with repeated urinary tract infections, residual urine, unexplained fever, vague abdominal complaints, or flank pain should be studied for possible vesicoureteral reflux. Conservative measures directed at eliminating the cause or contributing factors should be tried first. If these fail, reimplantation of the ureters becomes a necessity to prevent total renal injury or loss. Any condition which can ultimately produce total renal destruction by progressively increasing back pressure or from repeated infections must be viewed as of grave significance and prognosis.

THERAPEUTICS

The Treatment of Idiopathic Thrombocytopenic Purpura: A Review of 93 Cases. E. J. Watson-Williams, A. I. S. Macpherson and S. Davidson. Lancet 2:221-226 (Aug. 2) 1958 [London].

The authors report on 28 male and 65 female patients, between the ages of less than 9 and 79 years, with idiopathic thrombocytopenic purpura. Twenty-six of the 93 patients did not receive specific treatment and were given whole-blood transfusion or hematinics. Of the remaining 67 patients, 31 received specific treatment which was instituted less than 100 days from the onset of symptoms (patients with a short history), and 36 received specific therapy which was instituted more than 100 days after the onset of symptoms (patients with a long history). Specific treatment consisted of steroid therapy with corticotropin (ACTH), cortisone, or prednisolone in 19 of the 31 patients with a short history, and in 8 of the 19 patients there occurred a complete remission which was maintained after treatment was stopped. Patients with a short history tended to have spontaneous remissions, and the onset of such remissions seemed to be hastened by steroid therapy. Steroid therapy was given to 23 patients with a long history, and 12 of these showed distinct improvement but this was never maintained for more than 60 days. In patients with a long history, the chances of a spontaneous remission or of a lasting remission from steroid therapy are small. Twelve of the 31 patients with a short history who did not receive steroids, and 7 who had failed to benefit from them, were subjected to splenectomy. Thirty-three of the 36 patients with a long history were treated by splenectomy, and 14 of the 33 had received preoperative steroid therapy. Splenectomy was followed by good results in more than 75% of the patients with a short history in whom a remission, spontaneous or induced, had not occurred. Splenectomy was followed by good results in 50 to 60% of the patients with a long history.

The results obtained suggest that the initial management of the patient with a short history of purpura should be blood transfusion, to replace any serious blood loss, and administration of cortisone (75 mg. every 6 hours) or prednisolone (15 mg. every 6 hours) for 3 weeks. If the platelet count rises during this time, there is a good chance that it will be maintained. If there is no improvement within 3 weeks, splenectomy should be performed in the expectation that at this time it will be followed by a good result in 75% of the patients. Patients with a long history of relapsing purpura should also be given a 3-week course of steroid therapy. All these patients should be subjected to splenectomy either during the steroid-induced remission or as soon as it is apparent that steroid treatment has failed to influence the platelet count. However, when a remission occurs, it may be justifiable to defer the operation in patients with milder cases, especially if the remission is a response to the first course of steroid treatment.

PATHOLOGY

Cerebral Blood Flow and Metabolism of the Brain During Acute Cerebrovascular Accidents: Effect of Certain Vasodilator Drugs. F. S. Feruglio and B. Migheli. Minerva med. 49:2440-2445 (June 20) 1958 (In Italian) [Turin, Italy].

The pharmacological effects of an Italian proprietary compound, Ronicol, made up of acetylcholine chloride, beta-pyridyl-carbinol, and pyridostigmine bromide, were investigated in 12 patients with acute cerebrovascular lesions of recent occurrence. Cerebral blood flow, oxygen utilization, and peripheral cerebrovascular resistance were measured by a method devised by Kety, immediately before and promptly after the intravenous administration of the compound. Fifteen observations were made on the 12 patients; these were divided into 2 groups, one consisting of 6 and the other of 9 observations.

The patients of the first group, all but 1 of whom were between 65 and 82 years of age, had small cerebrovascular lesions, either circumscribed (3 patients) or in the process of resolution (3 patients). Cerebral blood flow, oxygen utilization, and peripheral cerebrovascular resistance values deviated slightly from the normal values before the administration of Ronicol. The effect of the drug on these values was almost imperceptible. The patients of the second group, who were younger than those in the first group, had symptoms of recently developed acute and severe cerebrovascular lesions. The state of the cerebral blood flow and of the metabolism of the brain before the administration of the drug was the same as it was when the cerebral ictus developed. It consisted of a low cerebral blood flow, a reduced utilization of oxygen, and a significant increase in the peripheral cerebrovascular resistance. The sensory state of the patients was also affected, ranging from periodic breathing in some to coma in others. The administration of Ronicol to patients in this group produced an increased cerebral blood flow, a larger utilization of oxygen, and a decrease in the peripheral cerebrovascular resistance. The improved metabolism of the brain was evidenced by the disappearance of periodic breathing in the affected patients and by partial arousing of those patients who were in a semicomatose state.

Ronicol has thus proved to be effective in improving the cerebral blood flow and the metabolism of the brain during the first phase of cerebrovascular accidents. It is, however, less effective, or ineffective, in improving the cerebral blood flow and the metabolism of the brain after the first phase of the cerebral ictus, which is the most critical.

Nonpenetrating Traumatic Injury of the Heart. L. F. Parmley, W. C. Manion and T. W. Mattingly. Circulation 18:371-396 (Sept.) 1958 [New York].

Among 207,548 patients who died and on whom autopsies were performed at the Armed Forces Institute of Pathology in Washington, D. C., the authors detected 546 (0.1%) in whom death had resulted from nonpenetrating traumatic injury to the heart. These data show that the incidence of death resulting from cardiac injury caused by nonpenetrating trauma is low, although this type of injury is common, the lesion often being minimal and the morbidity slight. The character of forces responsible for the production of these injuries may be grouped in 7 categories: direct, indirect, compressive, decelerative, blast, concussive, and combined forces. Evaluation of the autopsy findings in the 546 patients and of the findings in additional clinical patients showed that myocardial rupture was most often the cause of death, whereas myocardial contusion and pericardial lesions were the most common injuries observed clinically. While ventricular rupture almost invariably was immediately fatal, 13 patients survived after atrial rupture for periods ranging from 30 minutes to 3 days. Since atrial rupture is amenable to surgical treatment, prompt diagnosis is essential. Five of 8 patients with rupture of the interatrial septum and 3 of 5 patients with rupture of the interventricular septum survived for short periods. These lesions may now be considered surgically correctible.

Of 105 patients with myocardial contusions or traumatic pericardial lacerations, 38 survived for varying lengths of time after the injury. Although such lesions are often well tolerated, the sequelae may be serious. Therefore, careful clinical evaluation of every traumatized person for possible cardiac injury is imperative, so that the more serious complications may be recognized and treated promptly. Thrombosis of a major coronary artery as a result of nonpenetrating trauma was not observed in this series and is considered rare. The effect of nonpenetrating trauma on a previously diseased heart is often serious, and the extent to which trauma aggravates a preexistent cardiac disease may often be hard to assess.

Transforaminal Curet Necropsy of Brain: A New Approach to Postmortem Tissue Diagnosis with Case History and Discussion. R. A. MacHaffie, G. J. Haslam, J. R. Walsh and I. D. Jones. Am. J. M. Sc. 236:284-289 (Sept.) 1958 [Philadelphia].

A technique for transforaminal curet autopsy on brain and meninges is described, which provides more adequate tissue specimens than the Vim-Silverman needle technique. The body preferably should not be embalmed prior to this procedure, as embalming prevents anteflexion of the neck to obtain the best approach to cerebral areas. This procedure does not, however, interfere with subsequent embalming of the brain or scalp. The position of choice is the lateral decubitus, with head anteflexed upon the chest in order to widen the aperture of the foramen magnum as much as possible. The head is maintained in anteflexion by an assistant while the pathologist inserts the guide needle of the Craig vertebral body curet through the foramen magnum in an anterocephalad direction. The curet cannula is slipped over the guide needle and advanced into the cisterna. The guide needle is removed, and cerebral spinal fluid is aspirated from the cisterna. When a sample has been obtained, a clean syringe is attached and the needle advanced to the right and inferiorly to enter the right lateral ventricle. Specimens of brain tissue are obtained from the right side of the midbrain, cerebral hemisphere, and pia-arachnoid and dura by toothed and hooked cutters, inserted within the lumen of the cannula, and by syringe aspiration. The cannula is withdrawn to the cisterna and inserted into the left side of the midbrain, lateral ventricle, and meninges for cutter biopsy. This technique is repeated in other areas of the brain until samples of all brain tissue except cerebellum and frontal lobes are obtained. The neck cannot be flexed sufficiently anteriorly to direct the needle into the cerebellum from this position.

The authors present the history of a 63-year-old man, who stated that he had been treated by a radiologist for chronic lymphocytic leukemia, and in whom a sternal puncture and cervical node biopsy revealed a chronic lymphatic leukemia. Nodes were palpated through the abdominal wall, and enlarged lymph nodes were present in the axillary, epitrochlear, femoral, and inguinal areas. Neurological examination was normal except for moderate nuchal rigidity and a positive Kernig's sign. Cryptococcus neoformans had been demonstrated in the leptomeninges with the aid of a mouse brain test. After the patient's death transforaminal curet autopsy on the brain confirmed the diagnosis of cerebral cryptococcosis. This method of curet autopsy on the brain appears to be adequate for the study of generalized brain disease and has the advantage of supplying larger fragments of tissue for study than the ordinary aspiration biopsy. While the results obtained with curet autopsy are not as exhaustive as those of the classical autopsy, it may be adequate to solve many problems of pathological and etiological nature, when the usual autopsy is denied.

RADIOLOGY

Trial Application of Cobalt Therapy to Buccal Cancers. Stuhl and Tournier. Presse méd. 66:1179-1180 (June 28) 1958 (In French) [Paris].

Radioactive cobalt (Co^{60}) was used with encouraging immediate results in treating 20 patients with advanced buccal cancers that were beyond the scope of ordinary radiotherapy. The basic physical characteristics of Co^{60} radiation are (1) its high energy (average, 1.25 mev) and (2) the fact that it is practically monochromatic, without soft components. The whole importance of cobalt therapy lies in certain theoretical advantages which flow from these characteristics. These are (1) the great activity, coupled with small size, of the source, which permits irradiation from a distance and a good geometric localization of the beam; (2) absorption by the superficial layers which is never preponderant, providing relative protection for the epidermis but making it impossible to use the skin reactions as a guide to treatment; (3) a depth dose which, for similar conditions of irradiation, is practically twice as great as that of the standard roentgentherapy; and (4) absorption which is practically the same for all tissues, whatever their density, so that the danger of radionecrosis of the bone is greatly reduced. This brief summary of the theoretical advantages of Co^{60} therapy shows how well adapted it is to the treatment of buccal cancers, which are often deep, hard to reach by the usual cross-fire technique, and masked by bone.

Techniques similar to those of conventional radiotherapy were purposely used in treating the patients in this series, so that the results of the 2 methods could be more easily compared. Two or more fields were generally used, and the tumor dose was always relatively high (5,000 to 8,000 r given at the rate of 150 to 250 r a day). Tolerance for the treatment, even with these high doses, was excellent. The administration of 6,000 r at the rate of 250 r a day was easily supported by the skin, which presented nothing more than a dry erythema followed by bronzing with mild itching for a fortnight. The mucosa, on the other hand, often showed mild, easily curable inflammation when the dose reached 3,000 r. No significant changes were noted in the general condition or, especially, in the blood picture during the treatment. The principal complications were radiation epithelitis or mucitis and, later, edema of either the soft tissues or the mucosa. The inflammatory changes were noted in 14 of the patients but necessitated definitive discontinuance of the treatment in only 1. Treatment had to be suspended in 3 others for one week, but after this interruption it was satisfactorily resumed. Significant radionecrosis of the bone did not develop in any of the patients, and a few were able to undergo dental extractions and operations involving bone resection after the radiation therapy. Radiocobalt therapy can also be reinstituted when necessary, e. g., in case of lymph-node involvement on the other side, or secondary extension to a neighboring organ. Several of these patients were still living at the time of writing, some with a follow-up of 1½ years, in spite of the fact that the disease was far advanced when the Co^{60} therapy was started.

ANESTHESIA

Employment of New Soviet Drugs for Potentiated Anesthesia in a Surgical Clinic. V. I. Kazansky and N. N. Rasstrigin. Khirurgiya 34:26-33 (No. 6) 1958 (In Russian) [Moscow].

Soviet drugs have been used by the authors since 1955 for potentiated local anesthesia, intubation oxygen-ether anesthesia, hibernation, and premedication of patients in employment of hypothermia. The following drugs are used: neuroplegics—aminasin, diprasin; analgesics—Anadol, promedol; parasympatholytics—metoxin (atropine). These drugs are combined into "lytic mixtures" in which the required and the main components are the neuroplegic and antihistaminic drugs. When these "lytic mixtures" are administered 15 to 20 minutes before the anesthestic, the patient becomes drowsy or even falls into a light sleep. There is a general inhibition of the central nervous system; the intensity of reactions to external stimulations is decreased; and fear of the operation disappears. This condition serves as a favorable background for any method of anesthetization. There is a block of the neurovegetative system, which helps to increase the resistance of the organism to operative trauma. Greater depth of anesthesia, with lesser expenditure of the main anesthetic, is attained when potentiated anesthesia is employed. Soviet drugs used in hypothermia promote its smooth course (absence of shivering, etc.). One of the side-effects in the administration of "lytic mixtures" is tachycardia due to the action of the neuroplegic and antihistaminic drugs. The authors consider it expedient to employ "lytic mixtures" for potentiation, since it gives a number of positive and valuable results.

Intraosseous Anesthesia in Operations on Extremities. V. P. Okhotsky. Khirurgiya 34:84-90 (No. 6) 1958 (In Russian) [Moscow].

Three hundred fifty surgical and orthopedic operations on extremities were carried out with the patients under intraosseous anesthesia. The essence of this method consists in the spread of Novocain solution, which has been injected into the spongy bone tissue, by osseous veins and surrounding soft tissues, with the following anesthetic action of Novocain on the nerve endings. The technique of this method of anesthetization consists in the following: A tourniquet is applied proximal to the operative field, and Novocain solution, 0.5%, is injected through a needle into the distal part of the metaphysis of the bone. The depth of anesthesia required for the operation is rapidly induced if the site of Novocain injection is chosen correctly. Complete circular anesthesia of the extremity up to the tourniquet is produced in 10 to 15 minutes. Toxic symptoms occasionally occur in intraosseous anesthesia, owing to rapid penetration of Novocain into the general circulation after removal of the tourniquet. Therefore, the author considers the increased individual sensitivity to Novocain a contraindication to intraosseous anesthesia. Before the operation a biological test should be carried out on all patients by intravenous injection of 10 ml. of 0.5% Novocain solution. If the patient is found to be sensitive, this method of anesthetization should not be employed.

PUBLIC HEALTH

Possibility of Infection of Human Subjects by Pigs with Coxsackie Virus Pneumonia. J. D. Verlinde, J. Versteeg and H. Beeuwkes. Nederl. tijdschr. geneesk. 102:1445-1447 (July 26) 1958 (In Dutch) [Amsterdam].

In July, 1957, a small but explosive epidemic occurred in a village of South Limburg province of the Netherlands. Eighteen children belonging to 6 families had fever (with temperatures up to 40.5 C [104.9 F]) and sore throat. The fever lasted for 3 days and subsided on the 4th day. Young pigs which had virus pneumonia were suspected of being the source of infection, since the children had visited a fair at which some of the pigs exhibited had had symptoms of this disease; the children became ill from 2 to 3 weeks after their visit to the fair. A Coxsackie virus, group A, type 5, was repeatedly isolated from the lungs of 2 pigs, and the serum obtained from the convalescing children showed a very high neutralization index to this strain. At first the strain was pneumotropic, but after 3 passages it was also myotropic for suckling mice. Intranasal inoculation of suckling-mouse carcass suspension produced virus pneumonia and specific antibody in healthy pigs.

Three Years' Experience with Poliomyelitis Vaccine—Ontario, 1955-57. W. G. Brown, G. K. Margin, B. Hannah and others. Canad. M. A. J. 79:155-162 (Aug. 1) 1958 [Toronto].

The 1955 poliomyelitis study group consisted of all the children, between the ages of 5 and 12 years, attending elementary schools in Ontario, the unvaccinated children serving as contratests. The total group was comprised of 672,249 children; 309,585 of these received 2 doses of vaccine, 6,924 received 1 dose (included for statistical purpose in the unvaccinated group), and 355,740 did not receive any vaccine. Among the 62 illnesses reported as possible poliomyelitis, 7 were classified as paralytic poliomyelitis (3 cases among vaccinated subjects), 4 as nonparalytic poliomyelitis, 8 as nonpoliomyelitic illness, and 43 as aseptic meningitis. The number of cases of poliomyelitis was too small to permit an opinion as to the effect of the vaccine. Of the 43 cases of aseptic meningitis, 23 yielded a Coxsackie or an enteric cytopathogenic human orphan (ECHO) virus on tissue culture.

The 1956 poliomyelitis study group was comprised of 840,000 vaccinated (2 or more doses of poliomyelitis vaccine) and 960,000 contratest or unvaccinated subjects. Among the 304 illnesses reported as poliomyelitis or polio-like illness, 76 were classified as paralytic poliomyelitis, 10 as nonparalytic poliomyelitis, 38 as nonpoliomyelitic illness, and 180 as aseptic meningitis. Five cases of paralytic poliomyelitis were reported among the 840,000 vaccinated children and 71 among the 960,000 unvaccinated, indicating that a significant difference existed in the attack rates of paralytic poliomyelitis between vaccinated and unvaccinated children. Of the 180 cases classified as aseptic meningitis, 103 yielded a cytopathogenic virus other than a poliomyelitic virus on tissue-culture examination.

The 1957 poliomyelitis study group included 1,800,000 vaccinated (2 or more doses of poliomyelitis vaccine) and 300,000 unvaccinated or contratest subjects. Among the 167 illnesses reported as poliomyelitis or polio-like illness, 38 were classified as paralytic poliomyelitis, 94 as aseptic meningitis, and 35 as nonpoliomyelitic illness. Seventeen of the 38 cases classified as paralytic poliomyelitis occurred among the 1,800,000 persons who had received 2 or more doses of poliomyelitis vaccine, 21 occurring among the 300,000 unvaccinated subjects, indicating, as did the previous year's study, a significant difference in the attack rates between vaccinated and unvaccinated children. Of *the 94 cases classified as aseptic meningitis,* 70 yielded a cytopathogenic virus other than a poliomyelitis virus on tissue culture. Experiences relating to the administration of over 4 million doses of poliomyelitis vaccine showed that the use of the immunizing agent was safe and remarkably free from associated reactions. No case of paralytic poliomyelitis was observed which could be ascribed to the vaccine.

The Management of Mass Casualties and the Flint Tornado. S. M. Lyttle. J. Michigan M. Soc. **57**:1112-1115 and 1151 (Aug.) 1958 [St. Paul].

On June 8, 1953, a tornado struck through the thinly populated area just to the north of Flint, Mich., and within 3 minutes it cut a swath 3 blocks wide and 4 miles in length; it completely demolished 200 homes and partially destroyed many others, killed 116 persons and injured 900 others, and caused an estimated property damage of $19,000,000. During the next 3 hours more than 500 tornado victims, along with relatives, friends, and volunteer workers, converged upon Hurley Hospital. This hospital, in which the surgical treatment of trauma has been well organized on a separate section for many years, has long been the trauma center for Flint. The presence of a well-organized house staff, including interns and residents, was of great value during the tornado emergency. It was the house staff who first saw the injured as they arrived at the hospital and initiated sorting and categorizing them according to type and severity of injuries. Although the hospital was already filled to overflowing with its regular patient load, 300 patients were admitted. Gradually, after admission, each floor became a self-contained sorting unit, and those patients who needed immediate definitive care emerged from the system.

The major injuries which were present in the 300 patients admitted were as follows: 49 craniocerebral injuries, with 11 associate skull fractures and 8 depressed skull fractures; 4 abdominal injuries, including 1 penetrating wound of the abdomen, 1 laceration of the mesentery and left kidney, 1 ruptured spleen, and 1 laceration of the transverse colon; 24 chest injuries, including traumatic pneumothorax, pulmonary contusions, cardiac arrest, traumatic rupture of the diaphragm, laceration of the lung, laceration of the pericardium, and hydropneumothorax; and 153 fractures of all types and in all locations. The relative number of open and closed fractures is not known. Closed and open reductions were done as indicated. Complex multiple injuries were the principal causes of death which occurred in 6 patients (2%). Most of the wound complications were those of infection Wound infections were first noted at about 48 hours, and until 96 hours, all wounds were examined every 5 or 6 hours, and smears and cultures were obtained. There were 35 cases of gas gangrene in the total of 57 wound infections. Of the 35 *patients with gas gangrene, major amputations were* done in 5 who showed evidence of systemic involvement and rapid dissolution. During the repeated inspection of wounds for gas bacillus infections and assemblyline method was used Dressings were removed at one station, wounds were inspected and cleansed at a second station and new dressings were applied at a third station This greatly facilitated the handling of the wounds

Sorting is the key to effective management of large numbers of casualties. It is the immediate grouping of patients according to type and seriousness of injury and their likelihood of survival and the establishment of priority for treatment to assure medical care of the greatest benefit to the largest number. The objectives of sorting are accomplished by designating patients within the following categories for treatment: (1) minimal; (2) immediate (3) delayed; and (4) expectant. Minimal treatment should be confined to patients who can be treated safely and sent on about their business. Immediate treatment should be carried out for patients for whom expedient procedures will save life or limb. Delayed treatment is for patients who, after having received emergency care, incur little risk by delay in further treatment. Expectant treatment should be reserved for patients so critically injured that only complicated and prolonged treatment offers any hope for improving life expectancy. Another important principle is that, except for lifesaving procedures, nothing should be done that decreases the patient's ability to care for himself.

Antibiotic Resistant Staphylococci: Familial Infections Caused by Exposure of Babies in Hospital Nurseries. V. Hurst and M. Grossman. California Med. **89**:107-110 (Aug.) 1958 [San Francisco].

The families of 2 infants, who have been subjected to an intensive follow-up study, are cited to illustrate the fact, that infants born during an outbreak of infection from a nursery Staphylococcus organism, which has been variously identified as

80/81, 52/42B/80/81, or 42B/44A/47C/52/80/81, frequently transmit the organism to members of their families. The first newborn infant left the hospital with impetigo, harboring the infectious strain on various unaffected portions of the skin and mucous membrane. In the second postpartum week the mother developed a breast abscess which yielded the same infectious strain. Within the first 8 months of the infant's life all the members of its family had a staphylococcic infection, but only the 7-year-old sibling received medical attention for a furuncle with lymphangitis from which the infectious strain was recovered. Cultures obtained from the nose and the throat of all the family members at 13 months were negative save for the 9-year-old child who had never had an infection. Cultures obtained from the skin and the nose of a 14-year-old cousin, seen 2 months later with impetigo of the lower extremities, grew the infectious staphylococci.

The second infant left the nursery as an asymptomatic carrier. Within the next 3 months various family members had intermittent boils, but only the infant received medical attention for the lesions. Culture materials from the nose and the throat, obtained from the entire family during the 4th month, revealed that the mother, the infant, and 2 siblings were carrying the infectious strain. The entire family was treated to no avail with tetracycline, 4 of the 5 previous carriers continuing to harbor the infectious strain in their throats. On last examination at 13 months the infectious strain was recovered from the nose, the throat, and a boil of the mother as well as from the nose and the throat of the 2 siblings. Although cultures from the nose and the throat of the infant have been negative, the strain seems securely rooted in this family and likely to persist. Antibiotic-resistant staphylococci are far more widely distributed in the community than is generally recognized. Their prevalence will continue to increase as long as newborn infants bring them home from the nursery and seed the population.

Unusual Salmonella Infections. A. Balows. J. Kentucky M. A. 56:770-773 (Aug.) 1958 [Louisville].

An indication of the protean nature of infections with Salmonella organisms is the fact that at present well over 400 species or serotypes are recognized, every one of which is pathogenic for man, animals, or both. Such an infection may present itself in the guise of various clinical and pseudosurgical syndromes. This fact and the lack of adequate laboratory facilities, coupled with a wide range of clinical manifestations, are largely responsible for the apparent failure to consider the Salmonella organism as the etiological agent in many undiagnosed infections.

The author reports 5 cases of unusual Salmonella infections. Upon removing the sutures from the incision of a 76-year-old woman who had been subjected to gastrectomy for reticulum-cell sarcoma, a small amount of exudate was noted at one end of the incision. Salmonella typhosa was isolated from a culture of this exudate. After a 10-day lapse the patient was readmitted with a severe diarrhea, and stool culture also grew out Sal. typhosa. The patient died after the 10th hospital day. A 36-year-old white restaurant operator was admitted with a tender swelling of the 8th rib on the right lateral side. Irrigation and drainage yielded a thin watery fluid; a growth of Sal. oranienburg was obtained from the culture. A 45-year-old man, with a history of a severe typhoid or thyphoid-like infection as a child, underwent sequestrectomy for persistent drainage after an operation on the left radius for osteomyelitis, which at one time had been diagnosed as tuberculosis. Curettage specimens were later identified on culture as Sal. schottmülleri (Sal. paratyphi B). The lesion healed and drainage stopped after extensive chloramphenicol therapy. A 78-year-old diabetic woman was admitted to hospital upon complaint of chills and fever and vague abdominal discomfort. Hospital findings were negative save for those of uncontrolled diabetes. A blood culture was taken, and a growth identified as Sal. choleraesuis was obtained. Upon readmission, the white blood cell count was elevated, and the patient was dyspneic. A roentgenogram of the chest now revealed a large amount of atelectasis of the right lung with encapsulated fluid. Serosanguineous fluid (150 cc.) removed from the right side of the chest yielded a growth of Sal. choleraesuis on culture. The patient died on the 12th hospital day, death being attributed to pneumonia with pleural effusion secondary to gastroenteritis caused by Sal. choleraesuis. A 63-year-old man, who as a young man had had a severe case of typhoid, was admitted to the urology service complaining of oliguria of one-year duration; he had now sought medical attention only after complete urinary retention, accompanied by severe pain, had ensued. An emergency meatomy was performed and was followed by a suprapubic cystostomy. Portions of necrotic prostatic tissue removed at prostatectomy shortly thereafter and some fluid obtained from bladder washings both yielded a growth identified on culture as Sal. typhosa. It was ascertained by verbal report that 1 and possibly 2 cases of typhoid were directly attributable to this patient. The occurrence of typhoid bacilli in prostatic tissue in the carrier is extremely rare, no cases having been found in the literature available.

In the opinion of the author Salmonella organisms must be considered in any type of bacterial infection, whether it be a simple abscess, meningitis, endocarditis, pelvic inflammatory disease, pneumonia, or urinary tract infection. Reserving a diagnosis of Salmonella infection for those patients who show a characteristic gastroenteritis or typhoidal or septic syndrome will continually fall short of revealing the true extent and diversity of salmonellosis.

BOOK REVIEWS

Advances in Pediatrics. Volume X. Editor: S. Z. Levine. Associate editors: John A. Anderson and others. Cloth. $9. Pp. 362, with illustrations. Year Book Publishers, Inc., 200 E. Illinois St., Chicago 11; Interscience Publishers, Ltd., 88-90 Chancery Lane, London, W. C. 2, England, 1958.

As part of a continuing series of comprehensive pediatric topics, this volume continues the excellent high standards, readability, and presentation of practical information. The subjects covered include psychological principles in pediatric practice, the pediatrician and the sick child, treatment of tuberculosis in childhood, convulsive disorders in infants and children, prevention of poliomyelitis by vaccination, staphylococcic infections in nurseries, muscular disorders of childhood, and the transfer of antibodies from mother to offspring. The detailed discussion on the pediatrician and the sick child should be of special value, and the general considerations on the practical application of the "art" of medicine should be useful to every practicing physician. This section should be of even greater value to the graduating medical student and house staff member. The total patient reactions to acute and chronic illness, along with management (including parent management), have never before been described in such a precise and all-encompassing manner.

The section describing the treatment of tuberculosis in childhood gives every practitioner sufficient general principles to treat, and, more important, to prevent, all forms of childhood tuberculosis. In the chapter on the prevention of poliomyelitis by vaccination, sufficient background material is presented to allow adequate interpretation of future advances in poliovirus vaccines, especially the orally administered type. The chapter on staphylococcic infections in nurseries is timely. The discussion on epidemiology and prevention of this extremely publicized entity merits the attention of every physician. The material is presented in such a manner as to allow those who are unfamiliar with the subject to evolve an initial understanding and to follow the details. The book is basically a reference volume, each section having an abundant bibliography.

Atlas der gastroenterologischen endoskopie. Von Prof. Dr. Reinhold Boller. Cloth. 288 marks. Pp. 381, with 313 illustrations. Urban & Schwarzenberg, Frankgasse 4, Vienna IX; Innsbruck, Austria, 1958.

This is one of the outstanding contributions to contemporary medical literature. The author began the work in 1942 by making sketches of some gastroscopic images. He then engaged an eminent painter, one Lepier, whom he had instructed in endoscopy, and for many years the artist and scientist worked together to evolve this magnificent volume. The painter observed the color and form of the various lesions, and the author advised him what aspects would be of greatest value to the reader. The entire work was a heroic undertaking. The author points out that color is much to be preferred to the usual monochrome of photography. The photographic lens may distort certain facets of the image, whereas color renditions, if properly presented, are the ideal means for studying and presenting to the observer what the author wishes to impart. The book depicts normal and abnormal areas not only by gastroscopy but also by laparoscopy, rectoscopy, and sigmoidoscopy. Under gastroscopy various abnormalities of the esophagus are shown. Over 30 illustrations are devoted to gastritis alone. This is followed by a comprehensive and thorough study of gastric ulcer followed by consideration of gastric polyps and malignancies. Under laparoscopy, the various images of the normal peritoneum and the various lesions observed intra-abdominally are brought to view. The same holds true for rectoscopy.

This work must be seen to be appreciated. It should be a priceless addition to any progressive surgeon's library. After each section are some blank pages on which the reader may record his own observations. The index is comprehensive. The publishers have apparently spared neither time nor money, and the author spared no effort to create this magnificent work. It can be highly recommended from every point of view. The text is written in German, and a great service to the medical and surgical profession would be rendered if the book were translated into English and other languages.

Die neuroallergischen Beziehungen in der Histopathologie der Multiplen Sklerose. Von Tibor Lehoczky. Cloth. $7. Pp. 176, with 209 illustrations. Verlag der Ungarischen Akademie der Wissenschaften, Alkotmány Utca 21, Budapest V, Hungary; Akademie-Verlag, Berlin, Germany, 1957.

This monograph reports on the histological examination of specimens from 20 patients with multiple sclerosis. In 16 of the patients the disease had a slowly progressive course and in 4 there were remissions and exacerbations. The latter subsequently developed a chronic trend. The author considers the optic system as the site of predilection for the lesions as indicated by the high incidence of involvement: the optic chiasm in 55%;

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

optic tract or optic nerve in up to 45%; the lateral geniculate body in up to 25%; the white matter around the posterior horn in up to 85%; that around the inferior horn in up to 55%; and the thalamus in up to 33%. He reviews in detail the histological features of thrombus formation, perivascular infiltration, the perivascular and perifocal variety of tissue edema and the "spongy degeneration" of areas remote from the lesions, perivascular parenchymatous rarefaction, and granuloma formation, and he discusses the significance of hemorrhage and the relative preservation of the nerve cells. He emphasizes that the morbid process in multiple sclerosis extends over the entire central nervous system and that in 60 to 80% there was histological evidence of recent activity. The latter was manifested clinically by the episodes of exacerbations of neurological symptoms.

According to Lehoczky the histopathological process of multiple sclerosis is characterized by (1) hyaline degeneration and fibrous "delimitation of the vascular wall"; (2) edema and swelling of the endothelial cells; (3) precapillary and capillary prestasis and stasis; (4) precapillary and capillary thrombosis; (5) perivascular infiltration (85% "polyblasts" and the rest lymphocytes); (6) hemorrhage; (7) perivascular, perifocal, and diffuse edema; (8) partial and total necrosis; (9) perivascular parenchymal rarefaction (microplaque); and (10) granuloma formation, and microglia and histiocytic reaction. He agrees with such previous investigators as Pette, Ferraro and co-workers, Wolf, Kabat and co-workers, Roizin and Kolb, Jerris, Alvord, Lumsden, Lhermitte, and Allegronza and Rovescalli that these features link the disease to experimental and human neuroallergy (Goddard). He believes that an allergic mechanism plays a deciding role in the cause and pathogenesis of multiple sclerosis. This monograph should be of value to all students of neurology and especially to those interested in the lesions and pathogenesis of the demyelinating diseases.

Lifetime Health Record. By David D. Rutstein, M.D., Professor of Preventive Medicine, Harvard Medical School, Boston. Cloth. $2.25. Pp. 127. Harvard University Press, 79 Garden St., Cambridge 38, Mass., 1958.

Valuable educational aspects are combined in this small volume with useful guides on the recording of important medical facts that all too often are forgotten or distorted with the passage of time. Perhaps the most significant feature is the ease with which the booklet can be used. In a two-page introduction, Rutstein provides a thorough explanation of how the records can be prepared and the reasons for their importance. Space is provided for birth information, as well as for recording data on immunizations. Growth records to age 25 can be kept, and there is an extended portion in which adult weight records can be maintained. Other items covered include hospital admissions, operations, accidents, and blood transfusions, both given and received. The record can be kept in even greater detail, if desired, with space for blood examinations results, urine tests, electrocardiograms, other special laboratory studies, and general results of routine health examinations. Of definite importance in many situations is information about major illnesses, reactions to drugs, and corrective devices that may be used. There is a special section for the female health record, with spaces for information regarding menses and pregnancies. Another special section permits listing of information about insurance policies, often not available when needed. On the last page, the author lists eight warning signals that can be readily understood by the average person. The warnings regarding early signs of cancer are incorporated into these. Although some physicians might be reluctant to encourage patient listing of items such as blood pressure, urine analysis, and blood cell counts, there are many aspects of this volume that recommend it highly. Unfortunately, its productive use still is subject to the inescapable fact that the average human being does not keep any sort of record adequately and consistently.

Negroes and Medicine. By Dietrich C. Reitzes. Cloth. $7. Pp. 400. Published for Commonwealth Fund by Harvard University Press, Cambridge 38, Mass.; Oxford University Press, Amen House, Warwick Sq., London, E. C. 4, England, 1958.

The study contained in this volume was conducted by the sociology department of the University of Chicago in the period Oct. 1, 1955, through March 31, 1957. It provides an interesting and informative presentation of opportunities for Negroes in medicine, and the general status of medical care for and by Negroes, through a comparative analysis of 14 communities across the United States. The first section of the report analyzes both Negro applicants to medical schools and Negro medical students. All data dealing with this analysis were obtained from such sources as the Association of American Medical Colleges, the registrars of Howard University School of Medicine and Meharry Medical College, and a questionnaire survey of other approved medical schools in the United States. Statistical information reveals that in 1950 the Negro population of the United States accounted for 10% of the total population, but only 2.2% of all physicians were Negro. Between 1938-1939 and 1955-1956 the number of Negro medical students increased 117% (from 350 to 761) while all medical students increased 34.4% (from 21,302 to 28,639). Furthermore, the proportion of Negro students attending medical schools other than Howard and Meharry gradually increased during this same period from 12.9% to 31.0%. This portion of the report deals with the problems encountered by Negro students during premedical years, the M. C. A. T. scores made by them, the various regional patterns and scores of Negroes in predominately white schools, the relationship between type of college and type of medical school, and other pertinent information.

The second and larger portion of the report deals with a study of medical care by and for Negroes, based on an analytic study of 14 communities representative of different areas of the nation (Philadelphia, New York, Boston, Chicago, Gary, Detroit, Indianapolis, Los Angeles, Washington, D. C., St. Louis, Kansas City, Mo.; Atlanta, Ga., New Orleans, and Nashville, Tenn.). These communities varied from "no integration" to relatively "high integration." In each community analysis the study included interviews with sociologists, local human relations organizations, and selected persons. The description of the findings in these various communities is enlightening for it presents the problems encountered by Negro physicians and Negro patients in these various environmental settings. Each community was found to be unique, but the study did reveal certain key factors which functioned in varying patterns. These include the existence and importance of predominately Negro hospitals, the presence of influential people or groups actively interested in integration, opportunities for professional contact between Negro and white physicians, type of strategy used by Negro physicians in obtaining hospital appointments, qualifications of the Negro physician, and their own professional relationships, as well as the race relations pattern characterizing each community. The volume is a valuable contribution to the field of race relations, medical education, and medical care.

The Cerebral-Palsied Child: A Guide for Parents. By Winthrop M. Phelps, M.D., Thomas W. Hopkins, Ph.D., and Robert Cousins. Foreword by Frances R. Horwich, Ph.D. Introduction by Dean W. Roberts, M.D., Director, National Society for Crippled Children and Adults, Inc., Chicago. Cloth. $3.95. Pp. 237. Simon & Schuster, Inc., 630 Fifth Ave., Rockefeller Center, New York 20, 1958.

No one can deny that the parents of handicapped children need and can benefit from professional guidance. Most books which purport to be guides for these perplexed parents fall short of their goal by being either too technical or too simple. This book, however, comes closer than previous ones to the ideal in serving as a guide to parents. The authors include an orthopedic surgeon who has pioneered in the study of the cerebral palsied child, the principal of a special school for handicapped children, and a professional writer who is the parent of a handicapped child. The book is clearly written and well organized. The first five chapters deal with the etiology, clinical syndromes, and treatment of the condition and the next five with the social and emotional problems, general hygiene, and parental aspects. Other chapters deal with recreation, education, and vocational rehabilitation. There are two appendixes, one giving a list of the United Cerebral Palsy Association affiliates, and another a somewhat incomplete regional directory of day and boarding schools for cerebral-palsied children. Although the book contains many controversial statements, it does supply a great deal of information of use not only to parents but also to therapists, teachers, and even physicians. In fact, the great amount of medical information encompassed in the book might easily be confusing to all but the most well-informed parents. The value to parents would have been enhanced if illustrations had been provided. In its present form, the book is probably more useful as a guide to those who will guide the parents than to the parents themselves.

Systemic Ophthalmology. Edited by Arnold Sorsby. Second edition. Cloth. $25. Pp. 682; 19, with 277 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, Butterworth & Co. (Publishers), Ltd., 88 Kingsway, London, W. C. 2, England, 1958.

This highly regarded textbook has been thoroughly revised and brought up to date. Its distinguished contributors discuss every ophthalmological lesion related to general disease. Of interest to American physicians, and as an indication of the international character of the text, 10 of the 34 authors are from the United States. The material has been arranged in six parts, dealing with (1) prenatal influences, (2) inflammations, allergic reactions, and infections, (3) nutritional, metabolic, and endocrine disturbances, (4) central nervous system, (5) cardiovascular and hematopoietic systems, and (6) other general disturbances. Copiously illustrated, with the inclusion of 24 color plates, well written, and ably edited, this book stands preeminent in its field. It should be a valuable reference book for the clinical ophthalmologist. To the general physician with an interest in ocular manifestations of systemic diseases it should likewise prove of immense practical value. It is unfortunate that its bulk makes perusal by the medical student unlikely, for it should be particularly helpful to him also.

Medical Electrical Equipment: Principles, Installation, Operation and Maintenance of Electrical Equipment used in Hospitals and Clinics. Advisory Editor: Robert E. Molloy, M.B., F.F.A., R.C.S. Contributors: P. S. Allgood and others. Cloth. $15. Pp. 312, with 238 illustrations. Philosophical Library, Inc., 15 E. 40th St., New York 16, 1958.

This text contains brief descriptions of the basic principles, operations, and maintenance of medical electric equipment which may be customarily found in general hospitals. Diagnostic or therapeutic indications for the use of this equipment or the techniques of application to the patient are not given. The equipment considered includes room illumination systems, airconditioning and refrigeration, x-ray apparatus, radioisotope diagnostic equipment, various heat and ultraviolet energy sources, and respiration equipment. The text deals with hospitals and equipment found in the United Kingdom, and its material is not directly applicable to the United States. The text may be of some help and interest to the hospital engineer, but it is doubtful that physicians generally will be interested in it.

Illustrated Preoperative and Postoperative Care. By Philip Thorek, M.D., F.A.C.S., F.I.C.S., Professor of Surgery, Cook County Graduate School of Medicine, Chicago. Cloth. $5. Pp. 98, with 60 illustrations, drawings by Carl T. Linden. J. B. Lippincott Company, East Washington Sq., Philadelphia 5; 4865 Western Ave., Montreal 6, Canada; Pitman Medical Publishing Company, Ltd., 45 New Oxford St., London, W. C. 1, England, 1958.

The author, who is well known for his knowledge of surgery and his writing, has put together in simple readable form a wealth of material without wasted words. Amply illustrated and attractively printed, this book should appeal to practitioner, intern, resident, nurse, and student. It simplifies some aspects of surgical care that seem to have become at times unnecessarily complicated. While it will not replace textbooks, it should provide quick reference and should be regarded as a companion to more comprehensive textbooks.

Clinical Enzymology. Edited by Gustav J. Martin, Sc.D., Research Director, National Drug Company, Philadelphia. Cloth. $6. Pp. 241, with illustrations. Little, Brown & Company, 34 Beacon St., Boston 6; J. & A. Churchill, Ltd., 104 Gloucester Place, Portman Sq., London, W. 1, England, 1958.

This volume contains a discussion on enzymes used in clinical medicine—largely on those administered parentally, but also a limited discussion on those used diagnostically. Its seven chapters are written by six authors. The subjects covered include protein biology, the chemistry and biochemistry of enzymes used clinically and their parental use in medicine, enzymes used in diagnosis, and polymerases. Much of the chapter on protein biology deals with enzymes. Their mode of action and the effect of concentration on their action as well as the antigenicity of enzyme preparation and the cell permeability to enzymes are discussed. The three chapters on the chemical, biochemical, and medicinal aspects of clinically used enzymes deal chiefly with trypsin, chymotrypsin, ribonuclease, hyaluronidase, cholinesterase, streptokinase, and desoxyribonuclease. The enzymes used for diagnostic purposes include the phosphatases, amylase, trypsin, lysozyme, hyaluronidase and antihyaluronidase, uropepsin, cholinesterase, and transaminase. This volume is somewhat uneven in that the chapters contributed by the editor have a more philosophical bent than those written by the other contributors, who tend to adhere to more factual material. This is probably because the subject matter of the latter group is more clearly defined. The book should be of interest to physicians, biological scientists, and students because it includes therapeutics. It collects and systematizes a great deal of scattered material on the parental use of enzymes, and, although much of the material is brief and sketchy, it contains numerous references to the original literature. A general index is also included.

Basic Cardiology. By T. E. Gumpert, M.B., Ch.B. F.R.C.P. Cloth. $6. Pp. 168, with 72 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2; John Wright & Sons, Ltd., 42-44, Triangle West, Bristol 8, England, 1958.

This unpretentious monograph appears to represent the accumulated experience of the author. The approach is that of the general physician with an abiding interest in cardiology. The book is not designed to replace a standard textbook on cardiology, but covers this field from the clinical viewpoint with a minimum of detail. The style is conversational, and the text is amusing in places. The material is up to date and is sound, clinically, for its level. There is room for disagreement with some of the electrocardiographic interpretations, and certain hemodynamic explanations, such as that of patent ductus arteriosus. There is no bibliography. The illustrations are good, although more care might have been taken in the preparation of some of them. This book should be of value as a review for the physician whose primary interest is not cardiology.

How to Write Scientific and Technical Papers. By Sam F. Trelease. [Volume is outgrowth of two earlier books: "Preparation of Scientific and Technical Papers" and "The Scientific Paper, How to Prepare It, How to Write It."] Cloth. $3.25. Pp. 185, with 6 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1958.

This is another handy-size volume on the preparation of papers, which contains little that is new but is offered in an interesting style. While most of the information available in books intended to guide authors in the scientific field could be summarized in a few pages, there is a need for amplifying presentations so that it becomes lively rather than dry. Furthermore, examples tend to impress the reader with the need for certain rules. This book, like others, serves its purpose, and it offers some additional information on the preparation of lantern slides, graphs, photographs, and other illustrations which may well make it especially appealing to a number of prospective users.

QUESTIONS AND ANSWERS

ALLERGIC CONJUNCTIVITIS

To the Editor:—*A treatment used for allergic conjunctivitis has been 4 cc. of 1:1,000 epinephrine, with rose water added to make 1 oz. However, there have been several complaints of a nervous, jittery feeling, very likely from the epinephrine. What percentage of the epinephrine is absorbed systemically from the eye?*

M.D., North Carolina.

Answer.—Allergic conjunctivitis is more often due to drugs than any other cause. Vasoconstrictors, such as epinephrine, naphazoline hydrochloride, ephedrine, and phenylephrine are mildly, if ever, allergenic or even irritative. Consequently, a solution containing one of the vasoconstrictors may be effective in providing relief of acute symptoms of pollen allergies more completely than any other local medicaments. In highly sensitive individuals who exhibit a violent reaction to intradermal or scratch tests, epinephrine (1:1,000) or any other vasoconstrictor should be instilled immediately. In the delayed type of allergic reactions in which the sensitization is a property of the cells themselves, the reactions are not affected by epinephrine. In mild cases of hay fever conjunctivitis, the use of combinations of vasoconstrictors, anesthetics, and cleansing agents are sufficient. Theodore and Schlossman (Ocular Allergy, Baltimore, Williams & Wilkins Co., 1958, p. 40) state that a mixture containing one drug from each of the following group is useful: (1) epinephrine (1:5,000), naphazoline (1:5,000), or phenylephrine (1:500); (2) cocaine, 0.33%; and (3) sodium propionate, 5%, or zinc sulfate, 0.25%. For relief of symptoms in vernal conjunctivitis, the subconjunctival injection of epinephrine (1:1,000) is recommended. In nonspecific therapy for allergic edema of the eyelids with conjunctivitis, the intravenous administration of antihistaminic drugs with ephedrine is especially valuable. Epinephrine is, of course, the drug of choice when anaphylactic reactions or edema of the glottis occur. Even in chronic cases it often affords relief in patients unresponsive to other medicaments. The injection of epinephrine (1:1,000) in amounts of 1 cc. is not uncommon in treatment of allergic reactions, migraine, and shock. In amounts of 1 to 5 cc., it has been administered by mouth to stop gastric hemorrhage. In the course of surgical operations, the injection of up to 10 cc. has frequently been used to aid in the control of bleeding. Epinephrine is not an allergenic agent, and its absorption does not cause sensitization or nervous or psychic reactions. Comparatively large amounts of it may be administered by injection, by instillation, or by mouth without danger of initiating unfavorable results. The weak solution of epinephrine alluded to in the question could not be regarded as a cause of "a nervous, jittery feeling" after instillation into the eyes at any frequency. It is not possible to estimate the absorption of the epinephrine through the conjunctiva, as some of the solution would be washed out by tears and squeezed out by blinking of the eyelids. Considering the amounts of epinephrine commonly used therapeutically in patients with allergy, it is not at all conceivable that absorption of epinephrine from the lotion, as indicated, is responsible for the symptoms described.

HEARING SCREENING TEST

To the Editor:—*In a school health program, the nurses do a hearing screening test on all first, fifth, and ninth grade students. In this screening examination, a sweep-type, pure tone audiometer is used. A level of 20 db. has been used in frequencies of 125 through 8,000 cps. There has been some question regarding the number of frequencies, as well as the rotation of frequencies in the testing. For instance, should the examination be begun in the right ear at 125 cps, with movement up through 8,000 cps, and then changed to the left ear starting at 8,000, with movement down to 125 cps? Please give information on the method of hearing screening tests in school children.* *Albert E. Woeltjen, M.D., Dixon, Ill.*

Answer.—The most desirable periodicity for school hearing screening examinations has not been definitely determined. The decision can best be made at the local level through consultation among school personnel, otologists, audiologists, and representatives of community health agencies. Routine annual testing in the lower grades with less frequent checks in the upper grades has been advocated. Regardless of the interval between routine tests, an individual check is warranted whenever a child shows signs of hearing impairment. A competent teacher, nurse, or even volunteer can learn to administer a screening test for hearing reasonably well. However, it is not generally advisable that the time of such personnel be used for hearing screening tests because of other responsibilities more

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

specific to their training. Whenever possible, an audiometric technician who is especially prepared to perform hearing screening tests in children should be available.

For individual screening, two tests are most commonly recommended; each employs the pure tone audiometer. In the sweep check test the intensity dial is usually set at 15 db. Ordinarily, the right ear is tested first. The left ear is then tested in the same way. The "screener" sweeps through the various frequencies rather quickly from 250 to 4,000 cps inclusive. The child is asked to indicate by nodding or with a hand signal whether he hears. The usual technique involves starting in the middle range and working up and down. Twenty-five to 30 children can be tested in an hour by the sweep check method. Children who fail to hear sounds at the 15-db. level at two or more frequencies in the same ear should be retested. For retesting, the threshold acuity test is generally recommended. The right ear is tested first, with an accluder covering the other ear. This procedure is much more accurate than the sweep check test but takes from 5 to 15 minutes for each child. Usually, the 1,000 cps frequency is selected as the starting point, with the intensity high enough for the child to hear. The sound is gradually lowered until it can no longer be heard and is then increased until it again becomes audible. This process is then repeated until a uniform response is obtained. Other frequencies are subsequently tested in the same way, covering a range from at least 250 to 8,000 cps. A retest is made of children who fail in either ear to hear the sounds at 15 db. at two or more of the above frequencies. Failure in the second test is reason for referral for otologic examination. Certain special group tests with use of the pure tone audiometer are available, such as the Massachusetts Hearing Test (Johnston, *J. Acoustical Soc. America* 20:697, 1948) and the Johnston Group Pure Tone Test (Johnston, *J. Speech & Hearing Disorders* 17:8, 1952). With these tests, screening can be done in more children in less time, but their accuracy as compared to the individual pure tone check is open to question.

NONSPECIFIC EPIDIDYMITIS

To the Editor:—*What is the currently recognized therapy for acute nonspecific epididymitis? Is bloody seminal fluid a usual accompaniment? What measures should be taken to determine etiology?*

M.D., New Jersey.

Answer.—Acute nonspecific epididymitis in the usual case is often caused by one or the other of the gram-negative bacilli frequently found in the urinary tract. Occasionally, this will be due to a staphylococcus or streptococcus. In those cases of acute epididymitis in conjunction with a subacute or acute infection of the lower urinary tract, chemotherapy or antibiotic therapy, depending on the organism found, is definitely indicated. However, in those patients who develop an acute epididymitis related to overdistention of the bladder or lifting of a heavy object when the bladder is full, experience has shown that chemotherapy or the use of the wonder drugs is of little or no value. Certainly at the present time, the immediate treatment should consist of definite support to the scrotum, and this is best done by the use of an athletic supporter. The usual sac-like supporter is of very little value. In most instances in the acute stage, the application of an ice bag to the inflamed part will be comforting. In the absence of general systemic reaction, such as fever, chills, malaise, and nausea, there is little to gain by keeping the patient in bed. These patients should be cautioned not to strain or push at the time of voiding and not to let the bladder get too distended. Fluids, of course, should be forced. At times, the pain in relation to the inflamed area is quite severe and the administration of codeine and aspirin by mouth or one ampul of 10% calcium gluconate given intramuscularly will be of benefit. In regard to the question of bloody seminal fluid, this is most likely due to the rupture of a small vein in relation to the verumontanum, and it is not believed to be due to an important lesion in the urinary tract. Usually, reassurance is enough to satisfy the patient, but, in the particularly apprehensive individual, cystoscopy and careful evaluation of the urethra may be indicated.

CHANGE OF RH FACTOR

To the Editor:—*Can the* Rh *factor change in a person without previous blood transfusion or previous pregnancy? Also, since an individual's blood group is dependent on the presence or absence of A and B blood group substances which are present at birth, can these groups change?*

E. Burns Gray, M.D., Widen, W. Va.

Answer.—The Rh factor of a person cannot change without a previous blood transfusion or pregnancy. It cannot change even with a previous pregnancy, but under certain circumstances it may appear to have changed after a previous blood transfusion. A transfusion of Rh-positive blood given to an Rh-negative recipient who does not have Rh antibodies will produce in him a mixture of Rh-positive and Rh-negative blood, because Rh-positive red blood cells will be tolerated by him until he develops Rh antibodies. During that time, a test of his blood could result in an erroneous interpretation that he is Rh-positive. Actually, the true nature of the blood can be readily recognized by an experienced examiner who will not overlook the large number of unagglutinated red cells. This potentially misleading situation is transient and remains only as long as it takes for the host to become sensitized to the heterologous blood cells. The same potentially misleading condition may result when Rh-negative blood is administered to an Rh-positive recipient. This is the case in exchange transfusions in fetal erythroblastosis. There, the Rh-positive infant may become transiently Rh-negative for a few weeks. Here too, the true blood group status will become manifest as soon as the infant begins producing Rh-positive erythrocytes. As soon as the production of his own red blood cells asserts itself, the infant has a mixture of his own Rh-positive red blood cells and of the transfused Rh-negative erythrocytes. Eventually, the transfused Rh-negative blood is eliminated and the true Rh-positive status reestablished. Exchange transfusions of Rh-negative blood given to Rh-positive adults have a similar effect and course. A and B blood groups cannot change with or without a previous blood transfusion or pregnancy. However, there is a special situation in the case of blood factor A which requires mentioning. There are several subgroups of A which differ in their ability to be clumped by corresponding agglutinating serum. This could possibly lead to errors and to seeming changes in the blood factor A, but only in the hand of the inexperienced worker. In a case reported recently (Van Loghem and others, *Vox Sanguinis* 2:16, 1957), a man suffering from chronic granulocytic leukemia was typed as group A in 1953, but a year later the A reacted less distinctly. However, the experienced examiner using well-established methods of identification could recognize the irregularity even without knowing about the previous result. He would have established the true blood group without much difficulty. In other words, even in this isolated instance there was no true change of the blood group. It is important to recognize that this and similar reports do not detract from the reliability of blood group determinations in medicolegal practice.

FIRST USE OF BLOOD TRANSFUSION

To the Editor:—*Please give historic information on the discoverers of blood transfusion and the use of blood plasma both in the United States and abroad.*

L. Le Bron Alexander, M.D., Rossville, Ga.

Answer.—The first authentic experimental blood transfusion was done by Richard Lower of Cornwall in 1666. By the use of quills and later silver tubes, he transfused blood from the carotid artery of one dog to the jugular vein of a second dog. The earliest successful human blood transfusion was accomplished by Jean Baptiste Denis, physician to King Louis XIV, in 1667. He injected 9 oz. of blood taken from the carotid artery of a lamb into the vein of a young man who was exsanguinated from numerous venesections. Scientific blood transfusion, however, began with James Blundell at St. Thomas Hospital in London in 1818; he had observed a woman die of uterine hemorrhage. He recorded his findings in his "Physiological Observations and Experiments" in 1824. In the United States, George Crile succeeded in 1907 in transfusion of blood from one person to another by the use of a cannula, one end of which was tied to the artery and the other end to the vein. In 1871 Bowditch and in 1872 Luciani used plasma and serum experimentally. In 1918 G. R. Wood, a captain in the British Army, recommended the use of citrated plasma in the treatment of emergencies in clearing stations and pointed out its advantages over whole blood. Max Strumia of Philadelphia put citrated blood plasma into routine use at the Bryn Mawr Hospital in 1927. J. Elliott of Salisbury, N. C., popularized plasma administration in 1936. Strumia employed dried plasma in 1938, and the British workers Edwards, Kay, and Davie used it in 1940.

CHRONIC LYMPHEDEMA OF THE ARM

To the Editor:—*Please give suggestions as to the management of chronic lymphedema of the left arm. A patient had a radical breast amputation 15 years ago. Since then, the arm has been swollen and has shown nonpitting induration, which is symptomless, except for the arm being heavy. However, over the past years she has had frequent episodes of high fever, chills, redness, swelling, and more induration of the arm. This is brought on usually by overusage of the arm, associated with extreme fatigue. Usually one or two injections of penicillin seems to hasten resolution, which requires about 48 to 72 hours.*

E. L. Petry, M.D., Kansas City, Mo.

Answer.—Chronic lymphedema of the arm after radical mastectomy is managed by vertical suspension of the arm with use of an overhanging sling. The sling supports the arm loosely at the wrist. Such a patient should be hospitalized and placed at bed rest for 10 days. Usually, within 10 days, the edema disappears. The arm is then measured for an elastic sleeve from the wrist to the axilla. The patient may remove the sleeve only on retiring but must place the arm on two pillows when at bed rest. The patient is instructed to utilize her sitting time for vertical arm elevation. This is achieved by constructing a sling fastened to a wall or to a floor lamp near the patient's chair. The sling should provide a nearly vertical position for the arm. In this manner, time spent in viewing television or in reading is simultaneously utilized for an effective therapy. If, in spite of these measures, the edema gradually recurs, the hospital regimen may have to be repeated once or twice a year. The results of the therapy depend on the etiology of the edema. The usual causes are a compromise of venous and lymphatic drainage at operation, postoperative wound infection, postoperative x-ray therapy, or carcinomatous involvement of the axilla. It is stated that the lymphedema occurred after the radical mastectomy 15 years ago. The extent of the time alone would rule out metastatic invasion. Since postoperative x-ray therapy is not mentioned, one may postulate that the genesis of this particular edema is due either to a venous compromise at surgery or to postoperative wound infection with subsequent fibrosis. A release of venous occlusion may occasionally be secured by a Z-plasty in the fibrotic area. This is hazardous, because the axillary vein is imbedded in the fibrous tissue and an injury to this vein could be disastrous.

MENIÈRE'S DISEASE

To the Editor:—*In 1957, a 66-year-old man suffered an acute, incomplete loss of hearing in his left ear, with tinnitus and a feeling of fulness. It was diagnosed as a hydrops cochleae and disappeared within a few days. It reappeared a few months later for only two days. After the attacks, his hearing was in no way impaired. In January, 1958, a mild case of influenza with pharyngitis and blockage of the Eustachian tubes turned into another attack of hydrops. In the beginning, there was again lowered acuity of hearing and tinnitus but also a terrific pressure in the left side of the head which came to a crisis with an attack of vertigo, without nausea or vomiting. No dizziness had occurred before. The pressure disappeared, but the incomplete loss of hearing and the tinnitus persisted. Only once, a few months later, has another severe attack of vertigo occurred. No therapy has helped. Nicotinic acid in a dosage large enough to flush the face caused only a subconjunctival hemorrhage. Antihistamines give rise to bladder trouble by causing slight ischuria. Please give suggestions for treatment.*

M.D., New York

Answer.—The history is entirely consistent with Menière's disease or, as it is now commonly called, endolymphatic hydrops. The pathology is known to be an increase in the amount of endolymphatic fluid within the labyrinth, but the reason for the increase is unknown. The low salt diet of Furstenberg, combined with potassium chloride or ammonium chloride, is helpful in some cases. Nicotinic acid has been helpful in a few cases. Occasionally, a diuretic helps to control the symptoms. One of the most successful medical treatments has been the use of extremely dilute histamine according to the method of Hansel. Recently, good results have been reported by the correction of an endocrine disturbance, most often of thyroid metabolism. Unfortunately, there remains a considerable number of cases in which medical treatment fails to control the symptoms. For these, destruction of the labyrinth may be necessary should there be continued attacks of incapacitating vertigo. The medical treatment of this condition is described by Derlacki (*Laryngoscope* 64:271, 1954).

HYPERTHYROIDISM

To the Editor:—*A patient, aged 70, has an elevated protein-bound iodine level and basal metabolism rate, with typical symptoms of hyperthyroidism (e. g., increased perspiration, loss of weight, and mild diarrhea). In addition, she has auricular fibrillation and a nodule about the size of a small marble. What would be the best treatment for her? Would surgical or medical treatment be advisable?*

Milton Sheiman, M.D., Bridgeport, Conn.

Answer.—This case presents several problems. It would be of some importance to know whether the hyperthyroidism results from toxic diffuse goiter (Grave's disease) or from hyperfunction of the nodule. In view of the small size of the nodule, the latter condition is unlikely but not entirely excluded. Radioiodine (I^{131}) studies, particularly with the gammagraph, should answer that question. Unsuspected malignant disease is present in about 5% of patients with nodular enlargements of the thyroid, and a "hot," or functioning, nodule is considerably less likely to be the seat of malignancy than a "cold" one. Except for the presence of the nodule, and assuming adequate collection of I^{131} by the thyroid gland, I^{131} would offer the most conservative treatment of hyperthyroidism in a person 70 years of age, and, in the absence of any clinical suggestion of cancer, treatment by this means would be justified in a patient at that age in spite of the presence of the small nodule. In this event, however, subsequent growth of the nodule would be adequate reason for prompt surgical intervention. If the patient is not debilitated and is in good general health, partial thyroidectomy, after proper preparation, should carry only minimal risk and would also be a justifiable method of treatment. The choice of either of the proposed forms of treatment is sufficiently equivocal in the instance cited so that neither could be urged too strongly in preference to the other.

ACTION OF ACTH IN ASTHMA

To the Editor:—*In the treatment of status asthmaticus, what is the pharmacological and physiological effect of ACTH? Is its effect accomplished by its action on the adrenal gland?* *M.D., Illinois.*

Answer.—The effect of ACTH in the doses necessary for the treatment of status asthmaticus is more accurately termed pharmacological rather than physiological. ACTH stimulates the activity of the adrenals to an excessive production of corticosteroid hormones related to hydrocortisone. The effect of these hormones on tissue is generally called "anti-inflammatory." In asthma, as in all allergy characterized by a wheal type (immediate) of skin reaction, the effect of the high concentration of these hormones is to decrease the edema of the tissue, restoring it to a nearly "normal" (nonallergic) state, with the resultant relief in symptoms. According to Rappaport and his co-workers (*A. M. A. Arch. Path.* 60:1, 1955; *J. Allergy* 24:35, 1953), the reduction of the edema is due to the effect of the hormones on the interstitial cement, usually termed ground substance, and on the perivascular sheaths. The ground substance is in a semifluid state during the allergic reaction. The perivascular sheaths are thinned, increasing the tendency to loss of fluid from the vessels. These factors favor edema of the allergic tissue. The increase in adrenal secretions after ACTH administration results in a change to a less fluid state of the ground substance and in a restoration in the normal thickness of the perivascular sheaths. These may be the important changes which result in lessened edema in this type of allergy, with resulting relief in symptoms.

VITAMIN B_{12} FOR PERNICIOUS ANEMIA

To the Editor:—*About two years ago, a woman, aged 70, noticed a feeling of pins and needles and numbness in her hands and feet; in June, 1957, she showed a typical blood picture of pernicious anemia. Cyanocobalamin, 100 mcg., was given daily for a time and then about every two weeks. Her blood and nervous conditions have much improved. What dosage of vitamin B_{12} should be necessary from now on? Has the insufflation method of administrating vitamin B_{12} proved satisfactory? Should any additional treatment be given?* *M.D., Alberta, Canada.*

Answer.—Experimentally, it has been determined that 30 mcg. of vitamin B_{12}, given once monthly, is adequate maintenance therapy in pernicious anemia after it has been brought under control. Normal serum vitamin B_{12} levels will result from this dosage schedule. In the opinion of most workers in this field, the insufflation method of administration is not a wise route in the average patient, even though, obviously, absorption takes place by this route. The method will be satisfactory for some, but most workers feel that it should not be used if neurological findings are present and, certainly, the method has not been widely adopted. Parenteral route of administration for vitamin B_{12} seems the most logical at the present time and preferable to administration either by insufflation or by the oral route. Some neurological improvement can occur up to two years after administration of therapy, so that it has been standard practice to administer 3 mcg. as often as once weekly until maximum improvement has occurred, after which time 30 mcg. every three to four weeks would be adequate treatment.

PRENATAL FETAL ELECTROCARDIOGRAM

To the Editor:—*Is there any way to record the electrocardiogram of the unborn human fetus in utero during the sixth or seventh month of pregnancy?*

Albert Abraham, M.D., Morristown, N. J.

Answer.—E. M. Southern (*Am. J. Obst. & Gynec.* 73:233, 1957) mentions that Easby in 1934 reported an electrocardiogram obtained from a 4½-month-old fetus. Marcel and Exchaquet (*Arch. mal. cœur* 34:39, 1941) took leads directly from the exposed heart of a 6-mm. human embryo and showed concordant QRS and T deflections. Raiha (*Acta pædiat.* 18:440, 1936) examined the electrocardiograms of 45 premature fetuses weighing from 1,000 to 2,500 Gm. (2 to 5½ lb.) and indicated that electrocardiographic complexes were recordable directly during embryonic life and followed a characteristic pattern. Southern studied the fetal electrocardiograms in 96 cases. The apparatus he used comprised a vector system with two amplifier channels, a lead selector system with facilities for both connections, and an oscilloscope for visual display of the leads selected. The technique is fully described in the article.

ENURESIS

To the Editor:—*Please give information concerning the water treatment of enuresis.*

Burton A. Finne, M.D., Chicago.

Answer.—It is not clear what is meant by "water treatment of enuresis." It is presumed that the questioner refers to the practice of restricting fluid intake, particularly in the evening, for the child who is suffering from nocturnal enuresis. This approach, and also that of feeding salty foods which would retain the fluids, has been found ineffectual. Nocturnal enuresis in a child above the age of 3 years, provided organic factors (which are rare) have been ruled out, is considered a psychosomatic reaction due to inadequate and faulty training or anxiety. The modern approach is not to restrict fluids in any form at any time but to reassure the child, particularly prior to bedtime. In persistent cases, a detailed study of the family and a psychiatric investigation of the child is indicated to uncover the causes of anxiety which may not be too apparent. The parent must be careful not to take a punitive attitude towards the enuresis but to commend the child for the nights that he does not wet the bed. In some cases, calmly waking the child and taking him to the bathroom helps.

LIFE SPAN AFTER SPLENECTOMY

To the Editor:—*Would there be any alteration in life span or any physiological alterations that are permanent after a splenectomy from a traumatic injury in a child 14 years of age?*

Thomas J. O'Brien, M.D., Buffalo.

Answer.—As a rule, no characteristic change in the life span or general physiology may be expected after removal of a normal spleen because of trauma. Under ordinary circumstances, the hemolymph glands in the abdomen take on the character and most of the functions of the spleen. If the spleen is removed because of disease, the underlying condition may affect the outcome. Certain blood changes appear after splenectomy, some compensatory and others associated with the absence of the spleen cells. According to some, there is an increased susceptibility to infection after splenectomy. No increase in the formation of malignant tumors has been reported. Some individuals have noted ease of exhaustion and other nonspecific symptions. On theoretical grounds, one would expect a disturbance in the portal tension and also a lack of immediate red blood cell compensation at high altitudes or during nonpressurized airplane flights.

ALOPECIA UNIVERSALIS

To the Editor:—*A woman, aged 33, started losing the hair on her head in spots, as in alopecia areata, and over a period of five months lost all her hair, including eyebrow and pubic hair. Along with this, her fingernails became brittle. Previous treatment has included vitamin B_{12} and thyroid. Please suggest tests which might show the source of this condition. Is there any treatment? What is the prognosis?*

B. R. Farner, M.D., Norfolk, Neb.

Answer.—The patient described has the manifestations of alopecia universalis. The diagnosis can be made only by examination. There are no tests which are specific for the condition. Other than for occasional nail changes, there are no other systemic manifestations which regularly accompany this condition. Treatments usually consist of the use of a mild stimulant applied to the affected areas. Some physicians use thyroid when it is not contraindicated by other conditions. With widespread alopecia, the prognosis of hair regrowth is not as good as for a localized patch. Some patients will show complete regrowth.

PROGRESSIVE MYOPIA

To the Editor:—*A 9-year-old boy has a family history of three generations of low grade (-1.00 sphere) myopia. He has multiple allergies, slight exophthalmos, and myopia. This has progressed from -0.50 sphere in February, 1957, to -1.00 sphere in March, 1958, and to -1.50 sphere in August, 1958. With -0.25 cylinder, his vision is 20/20. Could a thyroid disorder or the allergies be a causative factor for 100% increase of myopic spheres in 18 months?*

C. A. Campbell, M.D., Philadelphia.

Answer.—The gradual increase in myopia is neither unusual nor a cause for alarm. There is no connection between it and an allergic state or thyroid malfunction. The child should be tested once a year and his glasses changed as needed, but he should not be made an "eye invalid" by too much and too frequent examinations. Of course, it is understood that he has been instructed in using correct light coming from his left side, in keeping his close work at the proper distance, and in all the other well-established rules for the preservation of sight.

FOAMING OF THE URINE

To the Editor:—*What substances other than bile salts and bile pigments will lower the surface tension of the urine and produce foaming?*

Jack M. Troy, M.D., Hammond, Ind.

Answer.—For the most part, foaming in urine is caused by the presence of lyophilic sols, whether they increase or decrease surface tension. If they produce an appreciable change, they greatly facilitate the formation of foam. Thus, the chief cause of foaming in urine is the presence of proteins, mucoproteins, and mucin. It should be remembered that the urinary antiseptic agent, phenylazodiaminopyridine, a lyophilic azo dye, produces a yellow foam in urine not unlike that produced by bile pigments.

URTICARIAL RESPONSE TO TRAUMA

To the Editor:—*What is the cause of urticaria that occurs immediately after slight trauma? Is there any treatment? The patient is not allergic to anything.*

E. C. Kunde, M.D., Marengo, Ill.

Answer.—The ultimate cause of immediate urticarial reactions to slight trauma is not known. The precipitating cause is probably that such persons have a more labile histamine release mechanism, but why they should have a more labile histamine release system is not known. The problem has been discussed by Lorincz in the second chapter of the book "Allergic Dermatoses Due to Physical Agents" (edited by Baer, Philadelphia, J. B. Lippincott Company, 1956). The condition is difficult to treat. Antihistaminics are often of value in temporarily suppressing the lesions, but their use may have to be continued more or less indefinitely.

ACRYLIC LENS OPERATION

To the Editor:—*What is the current opinion in America on the operation in which an acrylic lens is substituted for the natural one?*

William Eldon, M.D., Mudeford, Hampshire, England.

Answer.—The acrylic lens operation of Ridley was never particularly popular in the United States and has been virtually discarded even by the early proponents. Briefly, the operation was associated with formidable complications and, occasionally, with loss of the eye. However, the procedure did prompt the development of the numerous types of anterior chamber lenses now available, and these appear likely to be quite popular.

DRUGS CONTRAINDICATED IN GLAUCOMA

To the Editor:—*What drugs, besides belladonna derivatives, are contraindicated in glaucoma or increased intraocular tension? Is chloroquine phosphate contraindicated?*

Marks S. Shaine, M.D., New York.

Answer.—The drugs chiefly contraindicated in glaucoma are atropine and its various derivatives or, in general, the cholinergic blocking agents. Chloroquine phosphate is not contraindicated in glaucoma. It is an antimalarial, and the blurring of vision which it may cause in high doses is part of its quinine-like action.

ALUMINUM HYDROXIDE AND DIETARY PHOSPHORUS

To the Editor:—*In reference to the question and answer on aluminum hydroxide and dietary phosphorus, which appeared in* The Journal, *Aug. 9, 1958, page 1904, it should be noted that another aluminum compound, basic aluminum carbonate, is described in "New and Nonofficial Drugs" (Council on Drugs of the American Medical Association, Philadelphia, J. B. Lippincott Company, 1958) as one-third more effective than aluminum hydroxide gel in phosphorus-binding power. Both of these drugs combine with the phosphate ion in the intestinal tract to form insoluble aluminum phosphate which is excreted as such in the stool, thus diminishing the amount of phosphate available for intestinal resorption and reducing urinary excretion of phosphate. Aluminum hydroxide gel was used by Freeman and Freeman* (Am. J. Dis. Child. 61:*981, 1941) to reduce the concentration of inorganic phosphorus in the serum of children with chronic ren*[illegible] *with a low phosphorus diet,* [illegible] (J. Urol. 53: *507, 1945) to be effective in the management of urinary phosphatic calculi. In subsequent metabolic studies* (J. A. M. A. 144:*1549-1556 [Dec. 30] 1950), Shorr demonstrated the greater phosphorus-binding capacity of basic aluminum carbonate.*

G. E. Farrar Jr., M.D.
Box 8299
Philadelphia 1.

SWIMMER'S ITCH

To the Editor:—*In the Questions and Answers section in* The Journal, *Aug. 23, 1958, page 2154, the question is raised as to whether swimmer's itch due to cercaria of avian schistosomiasis, as reported from Hawaii, was, or could be, contracted "as the result of swimming off the coast of Hawaii." As pathologist at Hilo Memorial Hospital, Hilo, Hawaii, in 1949, I saw several patients with swimmer's itch due to this cause. Without exception, these cases had been contracted from swimming in fresh water ponds and ditches inland from the ocean. I understand that this trouble also exists on Oahu. The consultant says that recently some type of "swimmer's itch" has been reported from several coastal areas of North America and Hawaii. As far as I know, "swimmer's itch" due to cutaneous cercaria is not contracted by swimming in the ocean.*

John H. Schaefer, M.D.
1525 S. Broadway
Los Angeles.

The above comment was referred to the consultant who answered the original question, and his reply follows.—Ed.

To the Editor:—*The following references are offered to give light on this question: Chu, "First Report of Presence of Dermatitis-Producing Marine Larval Schistosome in Hawaii"* (Science 115:*151, 1952); and Stunkard and Hinchliffe "Avian Blood Flukes Whose Larvae Cause 'Swimmer's Itch' of Ocean Beaches"* (J. Parasitol. 38:*248, 1951).*

DISSOLVING CORNEAL OPACITIES

To the Editor:—*In the question and answer on dissolving corneal opacities in* The Journal, *Sept. 6, 1958, page 138, edathamil calcium-disodium was recommended. This should be edathamil hydrogen-disodium. Literature may be obtained from the drug company that markets this product. It was originally used by the chief of ophthalmology at Harvard Medical School.*

AFL-CIO Urges Uniform Blood Banks . .

Atomic Energy Grants to Medical Schools . .

NIH Grants During October to $4,200,000 . .

FIRST FULL-YEAR STUDY OF INJURIES AND ILLNESSES COMPLETED

The Public Health Service, with the Census Bureau supplying poll takers, has completed the first full-year study of illnesses and injuries in U. S. families and of the number of physician visits. The sample involved 36,000 households, covering 115,000 persons. From the answers, projections were made and certain conclusions arrived at.

Such surveys will be carried on on a continuing basis as a result of the action of Congress in 1956 in authorizing the U. S. National Health Survey. Surgeon General Burney commented on the first study: "With this first annual summary, the health survey is beginning to produce a comprehensive picture that workers in the health fields have long needed."

According to the survey, illness and injury caused the American people to stay home from work or school, remain in bed, or otherwise cut down on normal activities for about 3.4 billion man-days during the year ending June 30, 1958. This total averages out to 20 days per person per year. Acute illnesses, with respiratory conditions leading the category, totalled 437,900,000, or an average of about 2.6 days per person.

About 47 million persons were injured seriously enough during the year to cause them to restrict their activities for a day or more or seek medical attention, the survey found. The injuries caused 424,100,000 days of restricted activity, or 2.5 days per person.

Under chronic conditions, the PHS listed circulatory diseases as the cause of 484,200,000 days of restricted activity, equivalent to about 2.9 per person. Digestive conditions ranked second and arthritis and rheumatism third.

The survey estimated that about 890 million physician visits (in offices, homes, outpatient clinics, or telephone calls) were made during the 12 months, or an average of 5.3 times per person.

Additional projections under physician visits: 1. More women than men use doctors' services—6.0 visits per person for females as against 4.5 for males. 2. The greatest number of visits occurred during the October-December quarter. 3. About three-fourths of the visits were for diagnosis and treatment, as against such preventive services as examinations and immunizations. 4. About two-thirds of the visits took place in offices. 5. The largest number of home visits were for persons 65 years of age or older.

REGULATIONS DRAWN UP FOR FOOD ADDITIVES CONTROL

An important step toward putting into effect the new federal law governing additives to foods has been taken with preparation by the Food and Drug Administration of a proposed list of 118 chemicals to be exempt from testing requirements.

Under the law, enacted by the last Congress, pretesting of chemicals must satisfy FDA before the substances may be added to foods. However, chemicals that have proved their safety by long usage may be declared exempt from the testing.

FDA's first list of exempt chemicals includes 61 preservatives, 29 buffers and neutralizers, 35 nutrients (such as vitamins, minerals, and amino acids), 5 nonnutritive sweeteners, 5 coloring agents, 5 stabilizers, 4 emulsifiers, and 34 other additives of various types. Thirty-six of the 118 are limited as to the quantity that may be used or the foods in which they may be used.

No flavoring materials are included in this list; they will be dealt with later. Coal-tar colors are subject to a different provision of the Food, Drug, and Cosmetic Act.

Complete text of the proposed regulations, including the list of the exempt chemicals, will be available after publication in the Federal Register. The list is not complete, FDA explains, as from time to time qualified experts will agree on other additives that are not a threat to health.

Publication of the list will allow qualified authorities to give the FDA their views as to whether further testing of the substances will be necessary. After the regulations and initial list are published in the Federal Register, 30 days will be allowed for the filing of suggested changes, deletions, or additions.

FDA has not specified in detail the type of scientific studies that must be made to determine safety of a nonexempt substance. Evaluation of test data will be based on criteria established by the food protection committee of the National Research Council, "unless equally good or better methods are proposed by the manufacturer."

A petition to have a food additive accepted must include a complete history of the substance, its composition, source, stability data, proposed quantity and method of use, control procedures, and appropriate tests to determine the amount of the additive in the finished food. Full information also must be furnished on any animal or other biological experiments designed to establish safety of the additive.

After a petition has been filed, notice to that effect will be published in the Federal Register. Subsequently, the regulation will be issued, giving the quantity of the additive to be used and the foods in which it may be used.

SECRETARY FLEMMING URGES MORE REHABILITATION EFFORTS

Addressing the Social Security Administration's medical advisory committee, Secretary Flemming of the Department of Health, Education, and Welfare stressed the importance of an increased effort to bring about the rehabilitation of disabled persons.

The Secretary said his department is putting more emphasis on medical research into disability, adding that "disability evaluation is not a static process but must keep pace with medical progress."

Mr. Flemming pointed out that the present disability payments section of the social security law, which offers OASI retirement benefits to persons 50 years and older who because of illness or injury are unable to do "any substantial gainful work," provides an ideal opportunity for channeling the disabled to state or other agencies where they may benefit from rehabilitation services.

The committee advises Social Security Administration on all phases of the disability program. Secretary Flemming praised it for developing, with the cooperation of the medical professions, "a sound and workable method of determining disability." He said this "difficult task" has been accomplished in a way "which does not interfere with doctor-patient relationships."

A person applying for disability benefits, or disability freeze protection (under which his Social Security benefits are not reduced because of years of forced unemployment), is directed first to consult a physician. The physician reports clinical findings, based on medical tests and laboratory examinations, after which a team, including at least one physician, decides whether the applicant qualifies as "disabled."

Dr. J. Duffy Hancock, professor of surgery at the University of Louisville School of Medicine, is chairman of the advisory committee.

AFL-CIO WANTS NATIONWIDE, UNIFORM, VOLUNTARY BLOOD BANK SYSTEM

The AFL-CIO wants all blood bank activities coordinated under a nationwide "uniform voluntary system."

Support for such a program was pledged by the labor organization's executive council at a meeting in Washington. It acted on a recommendation of the AFL-CIO's community services committee.

The council declared: "The AFL-CIO shall take appropriate steps to offer the full cooperation and active participation of organized labor to the Joint Blood Council and its cooperating agencies in the development and maintenance of a national blood program."

The Joint Council is made up of the American Medical Association, the American Hospital Association, the American Society of Clinical Pathologists, the American National Red Cross, and the American Association of Blood Banks. Its headquarters is in Washington, D. C., and the executive vice-president is Dr. Frank E. Wilson.

In the national blood organization, the AFL-CIO wants a uniform, voluntary system of blood banks, the requirement of uniform licensing standards, and a national clearing house or exchange for blood and blood credits.

AEC AWARDS $326,510 IN GRANTS: MEDICAL SCHOOLS BENEFIT

Atomic Energy Commission has approved $326,510 in grants to 30 colleges and universities, including 11 medical and public health schools, to help in buying training equipment.

Since start of the program in 1957, it has distributed almost $1,500,000 "for the purpose of helping colleges and universities expand their facilities for training in radiation biology and in the use of radioisotopes in the fields of agriculture, veterinary medicine, medicine and pharmacy, public health, and biology."

Another series of grants will be announced in the early spring of 1959. For information as to possibilities and requirements, write the director, division of biology and medicine, U. S. Atomic Energy Commission, Washington 25, D. C.

Largest grant ($25,000) went to the University of Minnesota School of Public Health. Minnesota's medical school also received $9,000. Other medical and public health schools to benefit were Albany Medical College of Union University, Boston University School of Medicine, University of California Medical Center at San Francisco, Indiana University School of Medicine, University of Puerto Rico School of Medicine, Temple Medical Center at Philadelphia, Southwestern Medical School at the University of Texas, Albert Einstein College of Medicine in New York, and University of Washington School of Public Health.

NIH RELEASES $4,200,000 IN GRANTS AND FELLOWSHIPS

During October, the last month for which complete information is available, the National Institutes of Health released a total of $4,200,000 in research grants and fellowships. Fellowships, valued at $603,344, went to 157 individuals, and $3,600,000 was given for 266 research grants.

Of the 266 research project grants, 86 (worth $641,615) went for new projects, more than half of them in arthritis, metabolic diseases, and mental health.

Highest institute total was $912,156 from the Heart Institute for 47 research projects. Other research totals by institutes were cancer $193,643, allergy and infectious diseases $268,528, arthritis and metabolic diseases $889,347, dental $44,800, mental $217,103, neurology and blindness $505,071, and general medical sciences $703,529.

MEPROBAMATE ADDICTION

Linn J. Boyd, M.D., Leonard Cammer, M.D., Michael G. Mulinos, M.D., Victor F. Huppert, M.D.
and
Harvey Hammer, A.B., New York

A STUDY OF THE long-term administration of meprobamate (Miltown) was undertaken, with special attention to symptoms observed on sudden withdrawal of the medication. This approach was used because meprobamate is commonly prescribed for daily use over long periods, because such chronic administration of drugs acting on the central nervous system may induce dependence, and because few well-controlled series of observations had been made with meprobamate as the sole medicament.

Despite prolonged use of clinically effective doses of meprobamate, no evidence of dependence, physical or psychic, manifested itself on sudden withdrawal of the drug and substitution of a placebo. The patients studied were elderly, and their reactions to central nervous system depressants were expected to be somewhat exaggerated. Dependence or habituation is not predicated solely on the prolonged administration of clinically effective doses. The personality of the subject, his previous drug history, and the size of the dose are important deciding factors in the development of addiction. The elimination of excessive anxiety, insomnia, or depression may be considered as a proper indication for the use of either stimulants or depressants. However, the sense of well-being engendered by these drugs may lead to their use far beyond the period necessary for the obtaining of symptomatic relief.

Plan of Study

With use of a double-blind technique, 90 patients, equally divided as to sex, were chosen from four wards at Bird S. Coler Hospital; 30 male and 30 female patients each received a capsule containing 400 mg. of meprobamate three times a day, and 15 male and 15 female patients were given a placebo capsule, physically indistinguishable from the meprobamate capsule. Each of the four groups was contained in a separate ward.

The subjects selected for this study were elderly patients, most of them ambulant, with common geriatric problems, who had been hospitalized primarily for custodial care. Their daily behavioral patterns, sleeping and eating habits, and emotional make-ups were well established and known to the nurses and attendants, making even minor deviations in reactions quickly recognizable.

Prior to the start of the study, each patient's personal history was reviewed thoroughly, psychiatric and neurological examinations were made in order to establish a norm for each patient, and eating and

sleeping habits and daily behavioral patterns were approximately quantitated and recorded. All untoward symptoms reported by the patients or any signs observed by the attendants were recorded daily, regardless of their apparent connection with the medication. Where occasional side-effects were severe enough to suggest an association with the medication, placebos were substituted for the meprobamate. After a short period of time, it was usually possible to resume medication. In addition, all previous medication affecting sleep or central nervous system functions was discontinued, and the patient reassured as to the significance of the change. Except for these preliminary steps, each patient pursued his regular routine and was given no indication that a special study was being conducted.

At the end of an eight-week period in preparation for the observance of any withdrawal symptoms, the meprobamate group was switched to the placebo for an additional two weeks. This step eliminated possible psychological disturbances referable to a change in the medication or to its abrupt discontinuance. The placebo group, comparable to the test group as to age, sex, environmental distribution, and previous medical status, was treated concomitantly for 10 weeks without interruption.

Table 1.—*Comparative Data on All Subjects in Meprobamate Habituation Study*

* M-P = meprobamate for eight weeks, followed without interruption by placebo for two weeks. P = placebo alone for 10 weeks.
† Includes fractures, osteoarthritis.

Results

The data are summarized in the tables. Because the patients were elderly (average age 75, table 1), their reactions to central nervous system depressants were expected to be somewhat exaggerated, and for this reason a close watch was kept for reactions due to overdosage, such as dizziness, somnolence, staggering, and falling. (It may here be emphasized that these patients had not presented symptomatic indications requiring medication of the type represented by meprobamate.)

It is seen from table 1 that more than half of the patients had cardiovascular disorders associated with senility, while about one-quarter suffered from skeletal defects, most of which were fractures, presumably due to previous falls. The conditions of the remainder had been diagnosed as follows: diabetes (1), multiple sclerosis (2), herniorrhaphy (2), paralysis agitans (3), cerebral complications (3), and miscellaneous benign conditions or operations (5).

Side-effects.—Table 2 shows the various complaints or medical conditions reported or observed during the study. These data were obtained from the nurses' detailed notes and from questions asked of the staff and patients by the responsible physician. Because there was no way of determining accurately the origin of the symptoms, these were recorded without regard to any apparent cause. It was felt that, in a double-blind, controlled study such as this, symptoms not specifically due to the medication would occur with equal frequency in both the meprobamate and the placebo groups.

It is evident that the percentile amount of complaints was about the same in all groups, if we do not include the symptoms induced by the pharmacological activity of meprobamate (depression of the central nervous system). Gastrointestinal upsets were about the same in the treated and untreated groups. Rashes appeared in four patients of the treated group; one case was diagnosed as a possible drug reaction by the consulting dermatologist. Rashes also appeared in four cases of the placebo group. All rashes disappeared spontaneously, without discontinuance of treatment.

Table 2.—*Summary of Complaints and Reactions in Meprobamate Habituation Study**

* Exclusive of increase in diurnal dozing or drowsiness. No patients had withdrawal symptoms.
† M-P = meprobamate, eight weeks; placebo, two weeks. P = placebo, 10 weeks.
‡ Some patients had symptoms in more than one category.
§ Three of these patients stumbled and fell before treatment with meprobamate or placebo.

Symptoms referable to the central nervous system are shown in table 2. These were dizziness, headache, mental confusion, increased nervousness, fussing, crying, and others. The other symptoms, too numerous and minor to mention, occurred about equally in the two groups. The number of falls recorded was greater in the treated than in the untreated group. This was interpreted as being due, in large part, to an overdosage reaction to the meprobamate and as indicating that the daily dose of 1,200 mg. was having its full effects. Of 11 patients in the meprobamate group for whom falls were recorded, two had had falls previously. Three of the remaining nine patients fell only once, despite continued medication; therefore, these falls were considered as accidental. One other patient fell again two weeks after discontinuance of therapy, suggesting that the fall could be only casually related to the medication. For these reasons, it is felt that only 5 of the 11 patients who fell while receiving meprobamate did so because of the central nervous system effects of the drug.

Behavior and Sleep Patterns.—The data summarized in table 3 are indicative of the proper pharmacological action of meprobamate as a central nervous system depressant. It appears that the meprobamate regimen did not interfere with appetite or increase inordinately the daytime dozing and drowsiness normally displayed by many of these elderly patients.

TABLE 3.—*Diurnal Behavior and Sleep Patterns During Meprobamate Habituation Study*

* M-P=meprobamate, eight weeks; placebo, two weeks. P=placebo, 10 weeks.

† G=good; F=fair; P=poor.

Sixty-four per cent of the patients receiving meprobamate reported that they slept better at night, compared to an improvement of only 28% in the placebo group.

Withdrawal Symptoms.—There were two patients, one man and one woman, whose temporary restlessness after meprobamate medication was stopped was such that it might possibly be ascribed to withdrawal of the medicament. However, during the study, such symptoms occurred in both the placebo and meprobamate groups. Obviously, withdrawal symptoms would not occur in the placebo group.

The actual "interpretation" of the symptoms was made from the data charts submitted for analysis and with full knowledge of the identity of the groups. It was deemed desirable to allow this slight adverse bias, because the burden of proof regarding lack of development of dependency would rest with the meprobamate medication. It is here stressed again that the purpose of this investigation was a search for the occurrence of symptoms pointing to the establishment of dependency. The patient had no way of knowing that the drug had been stopped and, therefore, was spared the ordinary "fuss and bother" symptoms likely to occur whenever chronically administered medication is suddenly withdrawn. The histories of the two patients whose symptoms could possibly be interpreted as due to withdrawal of the drug are reviewed here.

Report of Cases

CASE 1.—An alert man, aged 74, weighing 161 lb. (73 kg.), was hospitalized because of a fracture of the neck of the femur. He was ambulant, and he ate and slept well. His blood pressure was 120/80 mm. Hg, and it remained unchanged during the period of observation. Prior to taking the test dosage of meprobamate, he had been receiving APC tablets for pain in his hip.

During meprobamate therapy, his appetite continued to be good and he slept better at night, with some increase in diurnal drowsiness and dozing. After two weeks of treatment, he developed a low-grade fever and muscle aches and a diagnosis of virus infection was made. He appeared tired and weak; meprobamate therapy was discontinued. The next day, while trying to get out of bed, he fell once but sustained no injury. One week after his fever subsided, meprobamate therapy was reinstituted; it was continued for a month. He became progressively depressed, confused, and weak. Meprobamate was again withdrawn, this time only four days prior to its withdrawal in the group as a whole. He remained tired and confused during the first week of receiving the placebo capsules, and during the second week he developed a slight tremor and appeared somewhat depressed. However, his symptoms were not significantly worse than those which appeared in some patients in the placebo group; they are recorded as possibly being in the "withdrawal" category because of the nature of this study.

CASE 2.—A woman, 74 years of age, weighing 151 lb. (68.5 kg.), was hospitalized for custodial care, with a routine diagnosis of arteriosclerotic heart disease. Her initial blood pressure of 182/86 mm. Hg dropped to 158/68 mm. Hg at the end of the study. She was classified as neurotic and a chronic complainer. She had vague gastrointestinal symptoms, abdominal "pains," gas, anorexia, and occasional nausea. Her complaints continued during treatment with meprobamate, but she slept better at night and dozed more during the day.

After the change from meprobamate to the placebo, she continued her complaints but, in addition, stated that she had symptoms of palpitation and "jumpy stomach." In view of her gastrointestinal history, we believe that the nebulous complaints were not withdrawal symptoms but persistence of her previous pattern, possibly aggravated by the fact that she was not given therapy with magnesium trisilicate and aluminum hydroxide (Gelusil) as freely as before because of instructions to discontinue all previous medication. However, in accordance with the purpose of this study, we describe this case in detail as remotely suggesting withdrawal symptoms.

Comment

Many authorities have expressed the view that all drugs which are used therapeutically as central sedatives to promote sleep or to relieve anxiety may be habit-forming. This applies equally to central stimulants or euphoriants. With both types of drug, the essential factor, presumably, is the improvement in the sense of the well-being elicited by such drugs and the patient's desire to continue in this anxiety-free state.

The elimination of excessive anxiety, insomnia, or depression may be considered as a proper indication for the use of these two types of drug. However, the sense of well-being engendered by these drugs may lead to their use far beyond the period necessary for the obtaining of symptomatic relief.

Excessive administration of these drugs may result in physical dependence and the development of addiction,[1] characteristic of the use of barbiturates.[2] However, dependence or habituation is not predicated solely on the prolonged administration of clinically effective doses. The personality of the subject, his previous drug history, and the size of the dose are important deciding factors in the development of addiction.

The Seventh Report of the Expert Committee on Addiction-Producing Drugs of the World Health Organization takes the view that tranquilizers, although widely diverse in their chemical characteristics, must be classed as potentially habit-forming, because of their similar central sedative action. In addition, the occurrence of a characteristic withdrawal syndrome under conditions of excessive use has been regarded as indicative of a type of physical dependence similar to that with barbiturates, so that these drugs should be subjected to national control.

In considering the classification to which meprobamate belongs within the above definitions, much has been made of the clinical observations of Lemere,[1a] to the effect that "a psychological dependency on the drug is also undoubtedly created in certain patients." The ordinary use of meprobamate had led to overdosage in 13 of over 600 patients to whom Lemere administered it. Only in one patient, taking 16 tablets (6,400 mg.) of meprobamate daily for a month, were there severe symptoms (convulsions) from sudden withdrawal. Such doses were very high indeed, and the absence of withdrawal symptoms in the remainder of Lemere's patients who had been on prolonged therapy with effective daily doses may mean that the critical dose level for the development of meprobamate dependency is high and far beyond that used clinically.

In a previous study, Lemere [3] had stated that meprobamate was not habit-forming. It was with further clinical experience [4] that he was led to believe that this was not always the case. This further experience was derived from abuse of the drug by certain patients, but ordinary clinical doses were not implicated. Our data are in complete agreement with his as to the lack of addiction or dependency from ordinary clinical doses of meprobamate.

The findings obtained in our study are consistent with the view that effective daily doses of meprobamate in a group of 60 elderly patients did not result in either habituation or psychic or physical dependence. There was no desire or compulsion to continue to take the drug or to increase the dose, despite the fact that 400 mg. three times a day resulted in symptoms of overdosage and the drug had to be temporarily discontinued in several patients.

However, the virtual lack of symptoms of psychic dependence in this group may have been due to the fact that these patients had no psychic need for the meprobamate in the first place and, therefore, its abrupt withdrawal was not accompanied by the sudden release of neuropsychiatric symptoms in need of sedation. We interpret the lack of withdrawal symptoms as a failure of the meprobamate to induce psychic dependence or a craving for continued medication, in the manner of the barbiturates.

If meprobamate is capable of eliciting these symptoms, it must do so with larger doses given over longer periods, or only in certain individuals. The doses used in this study were evidently well below the critical dosage level described by Fraser for barbiturates, above which definite addiction can occur, but under which "a clinically significant degree of physical dependence" does not take place.

Stough [5] observed two convulsive seizures among 49 patients in the Oklahoma State Prison on abrup withdrawal of meprobamate. His patients were given from 3,200 to 6,400 mg. daily for four week prior to substitution of the meprobamate with placebos. Within 24 to 36 hours after withdrawal of meprobamate, the symptoms of which these patients formerly complained returned. However none showed any compulsive desire to continue the medication.

Later, 39 of these patients, supplemented by 11 new ones, were divided into two equal groups. One group received up to 1,200 mg. daily of meprobamate for five weeks. The second group received a gradually increased dose of meprobamate, until 2,400 mg. daily was being administered during the last two of six weeks of medication. At the end of five weeks, medication was reduced gradually placebos being substituted for the meprobamate. An absence of severe withdrawal symptoms was ascribed to the week-long, gradual withdrawal period, although in our patients, receiving 1,200 mg per day for eight weeks, there was no evidence of symptoms from abrupt withdrawal. However, it would appear desirable to withdraw meprobamate gradually, especially if the dosage is large and the treatment prolonged. Our results are in agreement with Stough's: no true habituation develops from the daily use of meprobamate.

Meprobamate does not have cumulative effects, because it is rapidly excreted or metabolized. As its administration was continued, some patients became more depressed, dozed more frequently, and began to stumble and fall. This suggested that no tolerance developed, but, on the contrary, as Lemere[4] indicated, that continued medication decreased the amounts needed to produce the same reaction.

Similar results were reported by Tucker and Wilensky[1b] during the clinical evaluation of meprobamate therapy in chronic schizophrenic patients. The doses used were large (up to 1,200 mg. three times a day) but elicited no inordinate depression, dozing, stumbling, or other side-effects, except for some transient gastric distress. On abrupt withdrawal of the drug, solitary grand mal seizures occurred in two of their patients. This, as well as other less serious signs of withdrawal, led them to suggest the need for gradual reduction of the dosage after the prolonged use of large amounts of the drug.

Summary

A controlled study was undertaken to determine the habit-forming propensities of meprobamate (Miltown). Sixty patients received 400 mg. three times a day, for eight weeks, and 30 patients received a placebo. The patients were elderly, under custodial care at a large city institution, and not in need of this type of medication. They were equally divided as to sex and clinical conditions.

Except for the tranquilizing effects induced by meprobamate and increased sleep and diurnal dozing due to it, there was no difference in the reactions of these patients when compared to those of the placebo controls. Despite prolonged use of clinically effective doses of meprobamate, no evidence of dependence, physical or psychic, manifested itself on sudden withdrawal of the drug and substitution of the placebo.

It is concluded that the dosage of meprobamate given, 400 mg. three time a day for eight weeks, was below any critical level that may be necessary for the development of dependency or addiction. This conclusion is consistent with observations of others that the occasional occurrence of withdrawal symptoms is associated with the use of very large doses of meprobamate and that ordinary clinical doses do not cause habituation.

260 Madison Ave. (16) (Dr. Mulinos).

The meprobamate used in this study was supplied as Miltown through the courtesy of Dr. F. M. Berger of Wallace Laboratories, New Brunswick, N. J.

THE PROBLEM OF SYPHILIS TODAY.—The disease is by no means eradicated, and physicians and public health officials must be ever alert to the possibility that syphilis may still produce disability, financial ruin, dementia, and death. . . . Rein stated that syphilis is on the rise again. A Public Health Report estimated that 1,921,000 persons in the United States have syphilis requiring treatment. Many states and large cities find their venereal disease appropriations inadequate to permit an effective and progressive program. Of major concern is the fact that high rates for primary, secondary, and early latent syphilis are in the age group of 15 to 19, reaching a peak at the 20- to 24-year group. Rapidly declining rates over the past several years have prompted the optimistic demobilization of venereal disease control forces, reassignments of personnel and reduction of case findings, and reduction of diagnostic and treatment facilities, leaving many areas without means to discover cases or to combat sudden outbreaks. Rein . . . stated that as physicians "we have the diagnostic tools and the therapeutic agents to control and even eradicate syphilis. But we are failing because of our own complacency about the disease, because of neglected educational programs, especially for the teenagers, and because of lack of interest or funds to find and treat the affected persons."—Herman Beerman, M.D., The Problem of Syphilis Today, *A. M. A. Archives of Dermatology,* August, 1958.

OCCUPATIONAL DISEASES–DIAGNOSIS AND PROPER METHOD OF REPORTING

Rutherford T. Johnstone, M.D., Los Angeles

While the reporting of an occupational disease is compulsory in most states, the system presently used leads to an accumulation of morbidity and mortality statistics, the greater portion of which are completely worthless. The diagnosis of an occupational disease is not subjected to the same scrutiny for accuracy as is a communicable disease diagnosis. Its medical, legal, and economic importance has not been sufficiently stressed. The prevention of an occupational disease is becoming increasingly difficult due to the vast number of new chemicals and new processes being introduced into the industrial environment. A partial solution to obtain proper diagnosis and reporting of occupational disease lies in supplanting the present system of allowing a careless brief report. A modified narrative form which would demand concise information regarding the history and the nature of exposure, signs, symptoms, laboratory data, and basis for conclusions is a necessity.

The law requires that the physician report specified communicable diseases to his local health officer. The statistics thus derived approach a high degree of reliability. This is due to the fact that by education and experience the physician learns well the signs and symptoms of those diseases common to the community. Likewise, in reporting a communicable disease a physician is impelled to be accurate in his diagnosis, because (1) he senses the seriousness of his obligation to the law, (2) he fears that an error on his part will force unnecessary restrictions and impositions upon the patient, and (3) an erroneous diagnosis will bring censure and reprimand. A diagnosis of smallpox or diphtheria is not apt to be a careless conjecture.

The reporting of an occupational disease is likewise compulsory in most states. Yet, for reasons to be mentioned, the system presently employed leads to an accumulation of morbidity and mortality statistics, a greater portion of which are completely worthless.

Difficulties in Diagnosis

In general medicine the physician practices within an area of readily accessible knowledge. Even on those occasions when the diagnosis of a clinical entity is initially obscure, obtaining aid is not difficult nor is the source of information distant from a physician's daily contact. In contrast, few physicians have had any formal training in occupational medicine, and actual experience in subsequent years is meager. Likewise, information regarding occupational disease is not readily accessible as it is in general medicine, since the subject matter is rarely found in the journals and textbooks utilized by the average physician. Finally, in making this comparison of disease reporting, cognizance must be given to the fact that the diagnosis of an occupational disease is not subjected to the same scrutiny for accuracy as is a communicable disease diagnosis. Its medical, legal, and economic importance has not been sufficiently stressed.

A further deterrent to accurate occupational disease reporting resides in the antiquated method in vogue. The insurance fraternity and the official agencies have not been realistic in facing the revolutionary changes which have occurred within the industrial environment. The system presently in use originated at the time the first Workman's Compensation Act was passed. At its inception, industrial medicine was concerned almost entirely with the treatment of trauma. Etiology was not a mystery. The cause of industrial trauma almost always wa evident, and liability was rarely contested. To report with accuracy and to estimate the degree o disability required only a minimum of words. A standard report form was conceived by the American Association of Labor Legislation in 1913. Wit only slight variation, it is still adhered to by mos states. Not only is the first examining physician obligated to fill out such a form, but he must do s within a short period of time, usually five days. Th original report goes to the state agency, with copie to the employer and the insurance carrier. The primary value of the short form lies in the fact that i is a handy, quick method of reporting an acciden immediately and thereby setting into action th machinery of compensation.

With the advent of the chemical age in industry an entirely different obligation imposed itself on th medical profession. Workers became exposed t multiple and varied substances, most of which ar potentially toxic. These may cause an illness whic mimics a nonoccupational disease. The etiology i therefore of prime importance. Whenever it i alleged that an illness resulted from an exposure t a toxic substance, it is necessary to identify th offending agent. To do so is a challenge not only t the inexperienced but, very often, to the experience industrial toxicologist.

Read in the Symposium on Occupational Medicine for the Private Practitioner before the Joint Meeting of the Section on Preventive Medicine and the American Academy of Occupational Medicine at the 107th Annual Meeting of the American Medical Association, San Francisco, June 24, 1958.

Take, for example, a situation which is usual rather than unusual. A patient confronts his doctor with a statement that his illness is due to an exposure to an industrial chemical, the name of which the patient does not know. If duly diligent, the doctor learns that the alleged offending agent is one bearing a long chemical name which is not familiar to him or that it bears a trade name. His search so far is like a baby's first step—just a feeble beginning. The follow-up, if properly pursued, involves telephone inquiries, correspondence, often a plant survey, search of the literature, and utilization of other areas of information. At this point in the discussion we return to the legal requirements in the short form, namely, that the report be made within five days, presumably with a correct diagnosis. This is rarely possible. In view of the amount of time needed to evaluate an occupational disease claim, official agencies should permit the physician to use the short form merely as a notification of medical investigation. On the short form could be stated "diagnostic procedures in process. A complete report will follow after further investigation."

A perusal of the medical reports sent to the Industrial Accident Commission reveals terse statements purporting to constitute a diagnosis. A few of these, picked at random, are as follows:

"Hepatitis caused by chlorinated hydrocarbons." Here it will be noted that no specific hydrocarbon has been isolated. There is the further inference that all hydrocarbons are hepatotoxic agents, whereas only a few are.

"Polyneuritis from exposure to toxic substance in oil refinery." The number of potentially toxic substances in an oil refinery is considerable. If any one of these is capable of producing a neuritis, it is not named.

"Lead poisoning—fumes from spray gun." No attempt is made here to show evidence that the substance in the spray gun contained lead.

Obviously in the examples just cited we find only conjectural statements—not substantiated diagnoses. From such are occupational disease statistics acquired. For this recognized problem there is no ready solution, but at the conclusion of this paper I will offer a suggestion.

Proper Approach to Diagnosis

At this moment it is obligatory that we consider the primary assignment of this paper, namely, the proper approach to the occupational disease diagnosis. This approach is of special value if the case under Workmen's Compensation is controverted.

History of Present Illness.—Cognizance must be taken of the time interval between the exposure and the onset of symptoms. The asphyxiant gases produce illness or death suddenly, not days or weeks later. This is likewise true of most of the anesthetic or narcotic gases, although with some there may be a secondary delayed involvement of one or more systems. On the other hand, intoxication from such substances as lead or benzene or methyl bromide is usually insidious and ill health from exposure to such may not be evident for weeks or months. The time interval in occupational medicine is somewhat similar to the incubation period recognized in general medicine.

Medical History.—The medical history in occupational disease diagnosis is a part of the clinical case history used in general medicine; however, previously existing systemic diseases may, at times, be aggravated by certain occupational exposures, and this factor deserves careful consideration.

Occupational History.—Most reports are insufficient in the area of occupational history. Ideally, the occupational history would leave no gap between the end of the worker's school years and his present occupation. Accounting for every occupational activity has special importance when one attempts to evaluate the significance of exposure to certain dusts, carcinogens, or aromatic hydrocarbons.

In obtaining the occupational history, the physician must not be deluded by the job title. A recently examined patient illustrates this point. For the past 20 years he had "worked out of" a union hiring hall as a boiler maker. Yet for the six months prior to being examined he was engaged in the reconstruction of a chemical plant and was unwittingly exposed to a toxic vapor. Therefore, regardless of the job title, it is obligatory to determine exactly what the worker did and exactly the chemicals to which he was exposed. Further, as in the general medical examination, an inventory of systems is made and a physical examination done.

Laboratory Studies.—As in general medicine, laboratory tests are made as indicated by signs, symptoms, or physical findings. But correlation of the results with the nature of the alleged exposure requires a knowledge of established facts. For example, an abnormal amount of lead in the urine or whole blood does not occur unless there has been an abnormal absorption of lead regardless of the source. On the other hand, evidence of liver dysfunction does not indicate that an exposure to a chlorinated hydrocarbon is necessarily the cause of the dysfunction. Interpretation of x-rays in cases of pulmonary pathology as related to occupational exposure requires considerable experience and judgment.

Plant Survey.—There are occasions when a survey of the worker's plant environment is essential to the final diagnosis. If the examining physician feels that an adequate plant survey is beyond his experience or competence, he should not omit this procedure from his study of the case. At such times he should call on the industrial hygienist to supply him with the information that he seeks. Failure to do so constitutes one of the major reasons why occupational statistics are so inaccurate. In contrast, utilization of the industrial hygienist contributes to the advancement of preventive medicine in industry.

Reference to the Literature.—Unless one has had formal training or considerable experience in occupational medicine, reference to the literature should be done more often than is customary in general medicine. The literature should be authentic and fairly recent. Observations made decades ago are usually not applicable today, except with a comparatively few diseases. Likewise, the opinions expressed by foreign writers are not always acceptable, since the constituents in the chemicals in use in other countries often vary from those in the United States and hygienic control measures may not be similar.

The Law of Specificity

If the procedures outlined in the previous paragraphs are adequately pursued the examining physician will have provided himself with the kind of information necessary to answer two questions arising out of an industrial exposure. He will have ascertained the nature of the worker's illness and he will have identified the substance alleged to have caused the illness. At this point he must ask himself this vital question: did the identified material cause the illness?

The final opinion reached is expressed in that portion of the narrative form termed "Conclusion" which is similar to that usually found in any medical paper except there are certain additional features. All opinions expressed in this final portion of the report should avoid technical terminology, since it is from this section that interested lay persons reach decisions pertaining to his or their particular function, such as the employer, insurance carrier, attorney, or the Industrial Accident Commission referee.

In arriving at a decision as to whether a given case is or is not an occupational disease, one should engage in a type of mental reasoning which I term the "matching process." Ever since it was laid down by Koch medicine has accepted and applied, whenever possible, the "law of specificity." Despite the generic term under which these are classified and despite having a comparable morphology, we recognize that all bacilli do not produce the same clinical picture or pathology. Equally important is the application of the law of specificity in occupational medicine. A commonly made error is the assumption that the chemicals bearing similar names or having similar formulas give rise to similar toxic reactions. This is because of our unfamiliarity with multiple chemicals used in industry. We readily recognize the difference between wood alcohol and whisky and thereby do not ascribe the same toxicity of methyl alcohol to ethyl alcohol. Neither should we assign the toxicity of tetrachloroethane to tetrachloroethylene or of ethylene chlorhydrin to ethylene dichloride, or as in other sounding similarities which could be cited.

In utilizing the matching process, the physician should ask and answer the following questions:

Is the suspected substance known to have noxious properties, or is it known to be inert? Many substances as they are normally handled in industry are harmless. Numerous metals and alloys as they exist in the so-called cold state are not toxic. Likewise, most dusts are inert.

To what degree has a suspected substance been absorbed? Certain irritants, for instance, affect the mucosa of the upper respiratory tract but are not absorbed to produce systemic reactions. Again, this is true of many of the dusts.

Is the substance under suspicion cumulative, or is it rapidly eliminated from the body? Nearly all of the anesthetic gases, such as carbon tetrachloride or trichloroethylene, are rapidly eliminated. On the other hand, methyl alcohol, methyl bromide, and certain metals, such as lead, are cumulative.

In what classification does the offending agent belong? One must recognize whether the offending agent is an asphyxiant, an irritant, or an anesthetic (narcotic) type of solvent gas. One must distinguish between aliphatic and aromatic substances. One must differentiate inert dusts from those capable of causing a reactive fibrosis.

Did an undue exposure actually occur? There is considerable difference between mere exposure and overexposure. The fact that a toxic substance exists within the worker's environment does not mean that he has absorbed harmful amounts. At times it may be necessary to have measurements of the concentration of the gas or dust in the worker's environment and to compare the results with the recognized maximum allowable concentrations. Likewise, one must take cognizance of those substances capable of producing intoxication after a single undue exposure in contrast to those requiring a prolonged exposure before reaction occurs.

Are the laboratory data confirmatory of intoxication and/or of systemic injury?

The final step in the matching process is the application of the epidemiologic and biostatistical disciplines. In each given case involving an identified etiology, is the entire clinical picture one which time and experience have established for that agent under similar circumstances?

The conclusion of the narrative form should end with the opinion that the condition is or is not of occupational origin. If the physician believes it is due to an industrial exposure, he should state the expected length of temporary disability and indicate the nature of the treatment. Any anticipated permanent disability should be estimated in terms of degree.

Comment

Fundamental to the purpose of the Workmen's Compensation Act is the prevention of accidents or occupational ill-health. This is accomplished to an admirable degree by the health program in industry, which includes safety methods and industrial hygiene measures. However, the prevention of an occupational disease is becoming increasingly difficult due to the vast number of new chemicals and new processes being introduced into the industrial environment. Gathering information regarding the toxic effect of these chemicals, as well as spotting "trouble areas," depends in no minor degree on the accuracy of diagnosis.

Unfortunately, the short form used by the first reporting physician does not lend itself to accuracy in diagnosis. The meager space allotted for answers and the time limitation for "getting the report in" actually motivates a carelessness rarely tolerated in any other phase of medical practice.

A partial solution lies in supplanting the present system with a modified narrative form which would demand concise information regarding the history and the nature of exposure, signs, symptoms, laboratory data, and basis for conclusions. This could be done without engaging in the type of lengthy report described in the body of this paper. If a new, well-designed form were provided and if the intelligence of the questions asked induced an intelligent response, the time consumed would be little more than that now utilized with the present form. Furthermore, a properly constituted form could create interest and stimulate self-education in this phase of medicine.

The plea presented in this paper stems from the realization that for nearly 50 years the equitable administration of the Workmen's Compensation Act has been abused for reasons cited. It is not reasonable to continue to assume that the best minds in organized medicine, the insurance fraternity, and the state agencies cannot find means and methods of correcting to a measurable degree an unwarranted situation.

COMPENSATIONS TO THE PHYSICIAN IN OCCUPATIONAL MEDICINE

Elston L. Belknap, M.D., Milwaukee

The physician in occupational medicine is obliged to meet the challenge of the varying demands of industries in which new processes are being introduced every day and the diagnostic horizons are constantly widening. Therapeutic and prophylactic skills must be correspondingly broadened. Frequent visits to the plant and patient attention to employees' complaints result in the gradual accumulation of priceless experience. When the confidence of employees and management has been earned, the physician finds that industry can provide him not only with advantages of economic security but also with the assurance, in many instances, of financial support for a stimulating program of continued medical education and clinical research. Through the study of occupational disease the medical profession can and must contribute to modern industrial society.

"These shops are schools whence one can depart with more precise knowledge." [1] So wrote Ramazzini, an internist, a skilled clinician, and a professor of medicine 250 years ago. Blind at 81 years of age, after 50 years of practice, he died of apoplexy on his way to give a lecture. It seems to me that this is a fitting quotation for a discussion of preventive medicine.

Thirty years of private practice in internal medicine, with consultation and teaching in the field of occupational medicine and also work as a part-time medical director, have led me to review my own experience regarding rewards which industry may offer the physician in occupational medicine and to consider whether these experiences might be of value to younger men who currently consider entering this field.

Compensations to the physician in occupational medicine, in my opinion, are the satisfactions derived from the practice of a wide range of scientific techniques, in situations often requiring the utmost in human understanding. Such practice can also have a firm economic foundation.

We hear a great deal of late about the specialist learning more and more about less and less. In the ever-broadening field of occupational medicine, the consultant must learn more and more about more and more. To demonstrate these varied demands, in one recent month, besides my regular teaching and plant responsibilities, I was called on to make widely divergent diagnostic decisions, based not only on the medical examinations but also on first-hand plant surveys in several different industries.

Read in the Symposium on Occupational Medicine for the Private Practitioner before the Joint Meeting of the Section on Preventive Medicine and the American Academy of Occupational Medicine at the 107th Annual Meeting of the American Medical Association, San Francisco, June 24, 1958.

The following five problems presented themselves: (1) evaluation of a possible residual from heavy manganese inhalation which had occurred 10 years previously; (2) consideration of whether asthma could be precipitated by inhaling one or two breaths of trichloroethylene through a lighted cigarette, with alleged resultant inhalation of phosgene; (3) study of a possible precipitation by lead absorption of an attack of severe and nearly fatal familial porphyria supposedly due to skin contact with leaded gasoline and inhalation of such gasoline vapor involved in the filling of gas trucks from large outdoor storage tanks; (4) examination of the case of a hospital physiotherapist who received an electric shock with resultant polyneuritis or causalgia; and (5) review of possibility of lead exposure resulting from an experimental process in the electronics industry. With such widening diagnostic horizons comes the thrill of variety, a reward in itself.

Diagnostic Skills

In occupational medicine, as in every other branch of the art of medicine, diagnostic skills stand preeminent. Added to the searching history necessary for the usual medical study, physicians in occupational medicine have learned from the master Ramazzini to follow up in great detail that simple question, "What is your trade?"

Every occupation followed by the patient must be covered—not just the most recent one—as far back as his very first job. The fact that a new patient in his late 60's was a janitor just prior to his admission to the county hospital may not be the most pertinent statistic. For instance, a patient with terminal pneumonia had worked for several years as a gardener on a large estate, but he had previously worked for 35 years as a deep-rock iron miner in northern Wisconsin. The postmortem examination revealed a far-advanced silicotuberculosis, entirely unsuspected because the patient had been thought of only as a gardener in a wholesome outdoor job.

In another instance, a man died of apparently simple acute pneumonia. Just before the patient's death, an unusually alert resident asked the important question: "What is your trade?" This young physician then rapidly pieced together a story of recent inhalation of cadmium fumes. Because they were not oriented to the subject of occupational medicine, the family physician and the staff of a private hospital had not suspected this before the patient finally came to a large public institution in extremis. Later investigation showed that, a week before death, the man had been instructed by a foreman, ignorant of the fatal potentialities involved, to clean out an old cadmium plating tank by melting off the cadmium residue with an oxy-acetylene burning torch. The fuming temperature of cadmium is about 1,500 F, while the temperature of the torch cutting flame was well over 3,000 F. The fatal pulmonary edema was directly traceable to the alveolar burn resulting from the inhalation of cadmium fumes.

Aside from coping with the large number of deleterious chemical agents in the worker's past and present environment, a physician in industry is charged with the responsibility of recognizing the significance of complaints. There is always the possibility that continued complaints may reveal that the worker has serious underlying psychotic tendencies. Patient attention to such a complaint may also lead to the discovery of a heretofore unsuspected dangerous industrial exposure. For example, I recall a case in which a man complained of serious headaches from working in a pit with his head partly hooded by a large casting as he welded with a carbon dioxide–shielded arc. By air analysis the fact was confirmed that, as admitted by the manufacturer of the machine, such welding equipment may give off a considerable amount of carbon monoxide near the point of weld. This accounted for the symptoms, which disappeared when a stream of uncontaminated air was directed across the breathing zone beneath the welding helmet.

Therapeutic Skills

Therapeutic skills in occupational medicine are now far removed from the simple removal of splinters or the repair of lacerations or crushing injuries. Prior to therapy, multiple diagnostic techniques required include a working familiarity with functional studies of all body systems; an understanding of methods of evaluation of metabolism and hematology, including in many instances bone marrow studies; a practical grasp of characteristic symptoms of workers exposed to toxic substances; and an ability to correlate knowledge of new processes and potential hazards in order to prevent disease and disability. Again beyond the realm of diagnosis for occupational disease, we now have added to our armamentarium of treatment the application of specific drugs such as BAL for mercury intoxication and the chelating agent edathamil calcium-disodium for lead intoxication.[2]

Nonoccupational disease is chiefly a problem for the family doctor. The physician in industry must maintain a close and friendly relationship with him. Frequently, emergency care must be given to members of the aging group in industry, including that for acute episodes of coronary disease. Such patients are then referred promptly to the care of the family physician. Later, however, rehiring such individuals must be considered. From research and practical knowledge pooled from experience all over the world, it is now known that in most instances such men can be rehired with safety for both the worker and the employer.[3] Such rehiring may serve a threefold purpose: (1) saving a man's justifiable pride in making his own living, (2) avoiding the necessity of his turning to public relief for support, and (3) conserving his skills built up over many years. Development of the courage required of the physician in making the decision to rehire such a worker can be one of his greatest rewards.

Prophylactic Skills

It is obvious that prevention is the best treatment of any occupational illness and injury. As far back as 1700, Ramazzini pointed out that it is the physician's responsibility "to suggest medical precautions for the prevention and treatment of such diseases as usually affect the workers."[1] Modern occupational medicine is both a challenge and a satisfaction because one is constantly engaged in the effort to prevent occupational disease and disability. This involves the physician's intimate knowledge of shop processes and industrial exposures. Such understanding can only come from periodic and unannounced study of the working place during plant tours, preferably in company with the safety-man and the industrial engineer. A few minutes spent in clinical observation of a man at his work in the shop may explain his physical disease or disability much more concisely and clearly than the best written report the physician may receive from supervising or safety personnel.

After management's confidence has been earned, the occupational physician is consulted in advance when a new process is to be put into production. He can then advise as to potential hazards rather than later see several cases of acute poisoning develop. He can suggest, for instance, that such relatively safe solvents as methylchloroform be substituted for such dangerous ones as benzene or carbon tetrachloride. If toxic substances must be used, the physician should be familiar with the general principles of engineering safeguards. For example, in planning for protection against lead poisoning he should understand the value of properly designed down-draft suction through slotted inspection tables, as in the case of assembly work in modern battery plants. Here, too, as a double safeguard, respirators may be used as a temporary measure of protection, but only until more adequate ventilation can be built into a production line of machines by the ventilation engineers. Such engineering familiarity of the physician is not acquired alone by an advanced degree in either engineering or industrial hygiene. It does require that every part-time or full-time industrial medical consultant use keen observation and experience gained from frequent plant tours.

Medical control of industrial inhalation hazards is important as an extra check on the efficiency of ventilation procedures. Though the concentration of dust, fume, vapor, or gas in the air to be breathed can be accurately studied by the industrial hygienist, actual evidence of human absorption of such substances can only be evaluated by the physician who studies a particular patient in his reaction to his environment. To be sure, it is ideal if engineers can guarantee that the maximum allowable concentration of a toxic material is never exceeded. Actually, however, machine breakdown and worker failure not infrequently cause unsuspected absorption of dangerous substances. To be able to track down the source of unexplained symptoms of occupational intoxication is a particularly stimulating and rewarding experience for the plant physician.

To obtain early warnings of such failure of ventilation control or worker alertness, the physician in charge of the health of the industrial worker must have in operation a systematic plan for periodic medical examination of the men potentially exposed. For this program specialized physical examination procedures and simple tests of blood and urine are readily available to the average physician, even in the smallest industry and in the smallest community. In this regard, it should be borne in mind that the vast bulk of the worker population is in the small industries, those employing from 5 to 500 workers, which are usually too small to afford a full-time medical staff. Here lurk some of the most serious death-dealing hazards, because they are unsuspected by employer and worker alike.[4] Consequently, informed part-time medical consultation to such small industries is one of the most vital and broadest opportunities of the medical profession.[5]

To be specific, in workers exposed to lead, for example, basic medical control studies should include an examination of gums under a lens, for lead lines; evaluation of extensor strength of the wrists; study of hemoglobin level and stipple cell counts; and qualitative study of the urine for porphyrin. None of these tests is subject to the error of air-contamination, and all can be done at frequent intervals of two to four weeks with no objection from the worker. They are all relatively inexpensive. Both the general physician and the internist can readily master all these procedures.

Most of these convenient and simple tests have been widely and successfully used in the United States, in Canada, and abroad for many years, in both large and small industries, as practical measures to evaluate the safe level of lead absorption. Some years ago, in a brass foundry in which lead exposure was unrecognized, I found evidence—in less than 20 minutes—of a high level of lead absorption by using equipment immediately available to every practitioner of medicine. This "equipment" included a 95-cent hand lens, perfect illumination by direct sunlight just outside of the foundry, and my own eyes. Six of 12 men pouring brass showed lead line of the gums, indicating a potentially dangerous lead absorption, though not necessarily lead intoxication. This quickly acquired information was as valuable to me, in sounding an immediate warning, as an elaborate and time-consuming quantitative analysis of blood and urine for lead levels. At times, to be sure, especially when engineering preventive technique is practically perfect, one can rely to a considerable degree on less frequent periodic quantitative analysis of blood and urine for lead and other materials. The practical, nonspecific qualitative techniques, however, are often rewarding to small industries, whereas the specific quantitative laboratory studies are more often available only to large organizations.

Skills in Human Relations

A further satisfying reward for a physician in occupational medicine can be his sense of a personal contribution in the field of human relations. Through his day-by-day contact with workers, in his office and out in the plant, the men come to learn that the physician in charge is primarily interested in their welfare and safety as he deals with them frankly, without subterfuge or evasion. It has been my experience that they so trust the plant physician that they come promptly to him with their fears about an unsafe process, even before they feel free to discuss them with the union steward or their own foreman. If a physician is honest with himself and others, he can become a key man in a health organization composed of the worker, management, and medical department.

In addition to the confidence of the worker regarding his work conditions, the plant physician's human contacts offer him another intangible recompense. Just as in the case of a family physician, the occupational physician may render invaluable aid as he counsels a worker struggling with personal problems involved in facing life and death at home. The rare art of listening, such as the skilled psychiatrist has learned from training and experience, when mastered by a plant physician can result in valuable furtherance of the employee's confidence. So skillful can the physician in industry become in understanding and fostering the working complex of labor, technician, and management that in a few instances such physicians have been chosen as vice-presidents in charge of all personnel problems.

It is a revealing experience to a highly individualistic person, which every doctor is, to work with a business organization where each activity is the result of many skills focused on a single problem. Indeed, when illness comes to the usually strong and well individual whom a physician has known in his full powers and ability to work in the plant, there is even more than the ordinary challenge in the effort to encourage the return of such a man to his earlier usefulness and responsibility.

Opportunities in Occupational Medicine

Aside from compensations gained from the effective use of scientific principles and of human factors of environmental medicine, the modern physician in industry must look at his economic situation in a realistic manner. As with many other physicians, he must balance the time and money spent in his long years of professional training against the time available in each busy and precious hour which he places at the disposal of industry. The supply of physicians qualified by graduate training for positions as full-time medical directors is at present entirely inadequate. The economic reward for such specially trained physicians' services includes not only an adequate salary in addition to absorption of office overhead but also important fringe benefits involved in inclusion in group employee plans for insurance and retirement, as well as a usual guarantee of continuous employment with regular hours.

For the physician engaged in general practice or in many of the specialties of internal medicine and surgery, there is an unequalled opportunity for part-time consultant work in industry. This may grow to involve at least 50% of the consultant's time if he has given special study to the problems involved. Techniques of the part-time consultant are not only those used for proper placement and periodic examination but also those required for specific toxicological hazards. If the physician has the endurance required for living what is really a double life, both in private practice and in part-time medical consultant work in industry, he may find that his gross financial reward is somewhat greater than that of the full-time medical director. As with the full-time medical director, the part-time industrial medical consultant must not undervalue the worth of his services. In my own experience this end is most fairly served by rendering a fee for the hour for time spent not only in medical examinations but also in plant surveys, as well as on measures devoted to the prevention of occupational disease and disability.

Industry can provide the physician consultant, be he part-time or full-time, not only advantages of economic security but also the assurance in many instances of financial support for a stimulating program of continued medical education and clinical research. Animal experiments are of great importance in modern medicine. We know that clinical observations are fully as important. In industry, the physician has the opportunity to compare on a clinical basis groups of men accidentally exposed to toxic substances with control groups of unexposed workers. From my own experience, no clinical test is too complicated or too expensive for enlightened industry to undertake when necessary. Under the guidance of an experienced clinician such controlled studies have proved of inestimable worth. They enable the physician to evaluate the effectiveness of various medical measures which may be used either in immediate treatment or in prevention of disease and physical disability associated with the occupational environment.

Industry has also come to realize that the medical department can make or break the efforts of the entire personnel organization. Labor, meaning people, is the largest cost item in industry. Workers often get their first impression of a company in the way they are handled at the time of a preemployment examination. Frequently, afterward, when they come in for emergency medical care, periodic reexamination, or counseling with intimate personal problems, this presents a key opportunity to further friendly relations between worker and management. Industries are accustomed to put a fair price on consultation in the field of engineering or invention. They are now learning to pay physicians in proportion to their skill and responsibility both as medical consultants and as potential experts in human relations.

Conclusions

To the industrial physician no greater challenge and resultant reward exists than that which can be achieved by preventive techniques and medical diagnoses. The meeting of such a challenge depends on both foresight and insight. This the medical profession can and must contribute to modern industrial society. The study and treatment of occupational disease has become more exactingly complex, but after 250 years perhaps our greatest satisfaction lies in confirming the worth of the original philosophy of Ramazzini, as he stated in 1700, "I have tried to unearth in the shops of craftsmen, for these shops are schools whence one can depart with more precise knowledge, whatever may appeal to the taste of investigators, and, which is the main thing, to suggest medical precautions for the prevention and treatment of such diseases as usually affect the workers."[1]

THE PHYSICIAN AS ADVISOR TO INDUSTRIAL MANAGEMENT

Clifford H. Keene, M.D., Oakland, Calif.

The physicians dealing with problems of occupational medicine and industrial injuries stand in various relations to industry. Some are in community practice, and among their patients are employees sent by management for treatment or for answers to specific questions. Others have become specialists in occupational medicine through experience and by academic training, and they are employed by industry, although they must function on an impartial basis. Finally, some physicians function as medical directors, as integral parts of management with responsibility for policy and for decision. The goal of organized labor is complete prepaid medical care for the worker, his dependents, and the retired person. As this setting changes, the physician will have to accept greater responsibilities, and the degree to which he is able to do this will affect the future practice of medicine.

If you are earning your daily bread by the practice of medicine in 1958, much of the money in your pocket got there from sources argued about and agreed on by a working man and his boss.

Beginning in 1910, the pangs of national conscience in the United States brought about the first of the state workmen's compensation acts providing income and medical care to an individual injured at work. The New Deal in 1935 fathered the Federal Insurance Contribution Act providing retirement income to working persons over 65 years of age or income to their surviving families. World War II froze wages and increased taxes and thereby prepared the way for "fringe benefits." The Internal Revenue Service then ruled that the cost of health and welfare programs which made up fringe benefits could be deducted as a business expense by an employer but were not considered income to an employee. In 1948 the National Labor Relations

---

Director of Medical Relations, Kaiser Industries Corporation.

Read in the Symposium on Occupational Medicine for the Private Practitioner before the Joint Meeting of the Section on Preventive Medicine and the American Academy of Occupational Medicine at the 107th Annual Meeting of the American Medical Association, San Francisco, June 24, 1958.

Board ruled that health and welfare plans and pensions were proper matters to be negotiated between unions and industrial management.

In the 1920's, I was an apprentice ironworker, Local No. 6, in Buffalo. My wage was $1 an hour. I worked 44 hours per week. Each week I received $44 in cash. There were no deductions, and I spent all of it without help. Not so today! For example, it has been calculated that a California worker with three dependents who earns $90 a week has a payroll cost to his employer of $115 per week, while the employee has a take-home pay of $70.36. This average employee and his boss contribute a total of $45.64 per week to comply with legal and negotiated programs. Contributions must be made for federal old age and survivors' insurance, state workmen's compensation, the California unemployment insurance program, and the California unemployment compensation disability program—all of which are required by law. As a result of union-management negotiation, this average industrial employee receives the benefits of a health and welfare package which probably includes life insurance, supplemental disability insurance, accidental death and dismemberment insurance, a pension plan, and some form of prepaid medical care. The medical profession is involved in almost every one of these social changes. As an astounding result, industry as a whole now pays as a cost of operation much of the bill for the medical welfare of the work force as a whole.

Role of the Physician in Industry

The economics of the practice of medicine have been completely altered by the social forces generated out of industry in the past 50 years.

Industrial Physicians.—No class of physicians is more involved in the complexity of these changes than the industrial physician. Indeed, it can be observed that a physician's broad value to an industry is proportional to the help which he gives in complying with the obligations of these social changes. It is my observation that few industrial physicians are fully aware of this aspect of their position. Follow me in a brief appraisal of the roles which the physician can play in the economics of industry.

The simplest relationship of a physician to industry occurs when he provides treatment in his office or in a local hospital to injured employees of a nearby plant. The employees are cared for and returned to work, and the relationship is terminated by the payment of the bill. This is an essential service required by the Workmen's Compensation Act, important to the individual, a small expense to the employer, and a source of some income to the doctor.

The next step involves the performance of physical examinations on employees or prospective employees. In the request by industry to examine and evaluate an employee, the doctor is being asked a simple question which may be "Is this man hurt?" "Can this employee work?" or "Should this person retire?" Here the physician assumes a significant responsibility, because he must express an opinion. This opinion may well be considered from the diverse viewpoints of labor and management. The several viewpoints may produce dissatisfaction leading to a remedy which heretofore has always increased cost.

The physician who performs a preemployment evaluation is being asked by management to answer three questions: "Is this individual capable of doing the job which we have offered him without harm to himself or danger to others?" "Is he an ordinary risk under the Workmen's Compensation laws?" "Can we expect to recover the investment which we make by hiring him?"

The industry, to say nothing of the individual, suffers by an injudicious medical opinion based on incomplete information or lack of familiarity with the circumstances of the job in question. If for any reason an applicant is declared not suitable for hire, it costs somebody some money. By virtue of the circumstances, the examining physician is at that moment the most able member of society to prevent another unproductive dependency on the resources of the group and ultimate cost to industry. Certainly the physician does not exceed his prerogative by informing the employer exactly where an individual could be used or by advising the individual just how to correct the inadequacy which disqualifies him for a job. The cumulative results of such actions on the part of all physicians who serve industry must be apparent.

The physician in community practice who cares for industrial injury and who performs preemployment examinations may carry out these functions in a competent professional manner yet be of incomplete value to the industry with which he is related. The fault here lies in communication. As I mentioned before, whenever industrial management sends an employee to a physician it is for treatment or for an answer to a question. In good conscience but with indifferent result, the physician can reply to management by saying something as follows: "Give this man a light job." "This person may work if there is no strain." "This individual can work if there is nothing to bother his hay fever." In advice such as this, he leaves the actual decision to someone else who will say what is light work for this man, what is bothersome to the hay fever of this man, or what is a strain for this man. These basic questions of medical nature will be settled by a safety man, a foreman, or a union steward. The physician may have answered in a vague way because he is vague about the industrial environment of his patient and is fearful of a positive statement. A visit to the plant by a physician is always welcomed and is a source of satisfaction to all. As a matter of practice in the Kaiser Industries, the performance on the premises of a plant of as much of the medical services as is feasible is required in order to promote the awareness of the problems of the plant on the part of medical department personnel.

Specialist in Occupational Medicine.—In the next higher category of physicians in industry is the employed specialist in occupational medicine. Through experience, and in the past decade by academic training, a class of physicians with special knowledge of industry has been created. This specialist possesses a trained viewpoint whereby he sees the worker as an inhabitant of an abnormal environment where through guidance of the man and control of his surroundings compatibility between a man and his job is obtained. This is the world of the plant physician who plays his role before "labor and management," the most critical audience now viewing the medical scene. This specialists' opinion is sought on every aspect and detail of the laws and union-management agreements which involve health or disability. It is true that the physician is employed by management, but he must function on an impartial basis. He achieves maximum consideration by diplomatic expression of his opinions, awareness of the prerogatives of management, and respect for employees as the patients which they are.

In addition to guarding the health of employees, it is in this daily contact with the interplay among interests that the industrial physician has opportunity to influence the future costs to his industry and the economics of his profession. For example, one of the characteristics of strong unionism is the practice of an employee to take his troubles to his union steward. This is especially true when he is dissatisfied with the workings of whatever general medical care plan happens to be in effect. In the mind of the employee, the program was acquired by union negotiation and its defects can be remedied in the same way. The plant physician can play an effective role if the steward feels he can appeal to him for aid. Many causes for grievance in the workings of the medical program can be disspelled by an explanation or settled by a telephone call from the plant physician to a fellow physician in private practice. The diplomatic plant physician can do much to insure that our present prepaid programs of medical care function with effectiveness. Let the physician keep in mind that the goal of organized labor is complete prepaid medical care for the worker, his dependents, and the retired person. If this cannot be provided within the framework of the present system, it is likely to be secured under governmental auspices. Both prospects involve increased cost to industry. The second is an unwelcome prospect to the profession.

Medical Director.—With the increasing burden on industry of the cost of nonsalary employment benefits, the importance of the physician in the councils of management has grown rapidly. Actually, there is no last and top step to which a physician can climb in the large American industries. Near the top, however, the medical director functions as an integral part of management with responsibility for policy and for decision. He speaks with and for management in the broad areas of health and medical welfare. In addition, he is a student of economic trends in medical care and is alert to the size of the dollar sign associated with all medical projects. He is a businessman who happens to have a degree in medicine.

Conclusions

The vortex of the vast changes in the practice of medicine during the past 50 years has been in industry. These changes have compounded rapidly the value of the physician in the councils of industrial management. The physician is offered great opportunity in modern industry but must accept greater responsibility. The effectiveness of the industrial physician bears considerable relationship to the future practice of medicine. In fact, what you do in industry will shape the medical practice of your sons and grandsons.

1924 Broadway (12).

REVERENCE FOR HUMAN LIFE.—He who attends the birth of the human race and sits at the bedside of a dying world, and throughout his career, serves, at times, as the temporary custodian of life, cannot be devoid of a great reverence for a higher power than his own. Religion is the fiber of which we weave our moral code, and medical ethics is essentially a moral code which physicians have set up for themselves, a code which has guided the profession since the times of Hippocrates, when he wrote: "A physician should be an upright man, instructed in the art of healing . . . modest, sober, patient, prompt to do his whole duty without anxiety; pious, without going so far as superstition, conducting himself with propriety in his profession, and in all the actions of his life." Twenty-two centuries have passed since those words were written. This suggests a thread that runs through the practice of medicine: that neither time, nor science nor men, can change—the physician's great reverence for human life marks him as a religious man. —J. R. Hudson, M.D., The Doctor Dons Many Hats, *Cincinnati Journal of Medicine*, October, 1958.

HOSPITAL EMPLOYEES–CORRIDOR CONSULTATIONS OR HEALTH MAINTENANCE?

Jean S. Felton, M.D., Oklahoma City

The creation of an employee health program in a hospital is a logical step in the provision of a fringe benefit to underpaid and frequently aged and disabled workers. The needs for medical surveillance in the hospital situation are multifold and relate to the built-in hazards of the operation of patient care. These hazards include infectious disease (tuberculosis, Q fever, homologous serum jaundice, staphylococcic infections, and other bacterial, viral, rickettsial, parasitic, and fungus disorders), contact dermatoses, ionizing radiation, and patient-induced trauma and other injuries. Estimation of the work capacity of applicants for work, medical preparation of accepted applicant for work, maintenance and improvement of health status of employees, medical supervision of the work environment, and medical care for illness and injury, compromise an ideal health service.

Closest to the sources of medical attention, yet farthest from scrupulously detailed, documented, and executed diagnosis and treatment are most of the hospital employees in the United States. Comprising 1,375,000 persons, and an industry of over 6 billion dollars in total expense, this occupation ranks high among America's manufacturing, commercial, sales, and service enterprises. In 1950, employment numbers in "medical and other services, including hospitals," ranked seventh to the following industries: agriculture, construction, wholesale trade, food and dairy products stores and milk retailing, eating and drinking places, and private households. In 1956, the total gross value of hospital assets was about 13 billion dollars and the combined payroll was nearly 4 billion dollars.

These figures are offered to give a sense of gross dimension to the population segment under consideration and its work sites. Were these data to be compiled from true industrial organizations engaged in creating the world's marketable goods, one would find extensive programs dedicated to preventive medicine and the health maintenance of the employee. Of the 500 largest industrial corporations in the United States,[1] ranked according to sales, nearly all have medical departments, most of them functioning on a full-time basis. In a survey conducted recently of 62 university medical centers,[2] only 50% conducted preplacement physical examinations on applicants for employment and even less offered immunization programs.

Hospitals and Health Services

Why has the establishment of health services to employees lagged so far behind in these institutions? Why are hospital personnel given secondary position to student groups in both the teaching center and the hospital providing a diploma program for student nurses? Most hospitals stem traditionally from charitable beginnings, and, because of these dedicated and humble headwaters, a certain sacrifice was expected and few personnel "extras" became available.

The hospital worker, particularly in a university center, comes usually from a lower socioeconomic group and is fitted into a low wage scale. Many in this group are aged or are physically marginal, if not definitely handicapped, persons. Little is offered in the form of fringe benefits in lieu of adequate monetary compensation. The hospital industry is not the most modern, and only recently have some of the institutions installed machine record systems, electronic cost accounting methods, or other time-saving and labor-saving devices common to industry. Fringe benefits seem to have escaped the awareness of administrators; in 1957, these benefits (nonwage payments) in all industries came to 49.5 cents per employee per hour.[3] Yet, these employees can be as much of a health hazard to the patients, students, and each other as any miscellaneous, unexamined group of visitors to a hospital. In only 21 of the 62 medical centers surveyed were the workers given chest examinations roentgenographically. Many of the persons currently in medical job categories are those with high disease attack rates, and many were formerly employed as domestics, whose "private physicians" are usually the outpatient departments of university or private hospitals. Further, it is not uncommon for semiskilled paramedical personnel and even professional nurses to hold two jobs, frequently working 16 hours in a single day. This results in some of the undesirable sequelae of "moonlighting," and both health and efficiency in job performance can become impaired.

Professor of Preventive Medicine and Public Health (Occupational Medicine), University of Oklahoma School of Medicine. Dr. Felton is now Professor of Occupational Health, School of Public Health, University of California at Los Angeles.

Read in the Symposium on Occupational Medicine for the Private Practitioner before the Joint Meeting of the Section on Preventive Medicine and the American Academy of Occupational Medicine at the 107th Annual Meeting of the American Medical Association, San Francisco, June 24, 1958.

Recent Action and Existing Programs

A. M. A.-A. H. A. Action.—For two years, a joint committee of the American Medical Association and the American Hospital Association has met to outline some principles for the establishment of health services in hospitals. Produced finally, with the approval of the Board of Trustees of the A. H. A. and the House of Delegates of the A. M. A. (May 19, 1957), was the document, "Guiding Principles for an Occupational Health Program in a Hospital Employee Group."

In its foreword it is stated, "Employees in hospitals are entitled to the same benefits in health maintenance and protection as are industrial employees. Therefore, programs of health services in hospitals should use the techniques of preventive medicine which have been found by experience in industry to approach constructively the health requirements of employees." The purposes and scope of such a service are outlined, and the required personnel and facilities are discussed.

It has been questioned why one decants off this special group for occupational health consideration without doing the same for other categories of workers in other industries. A member of the Council on Industrial Health expressed it succinctly when he said, "In some hospitals, employees are like the cobbler's children who have no shoes—they have inadequate health protection in an institution of healing." In an establishment where there can be 225 different job classifications, from custodian to superintendent, there are the same needs for preventive health maintenance of the personnel as in any plant, warehouse, research laboratory, department store, or utility company, and perhaps more because of certain hazards peculiar to its operation.

The A. M. A.-A. H. A. publication describes in general the kind of program envisioned for hospital installations, and it will not be necessary to repeat its premises or primary points. However, it is felt that one can emphasize the objectives of such a program, and these can be stated as follows: to increase the health of the hospital worker, to increase efficiency, to minimize illness-absenteeism, to improve employer-employee relationships, to identify job-related personnel problems for resolution, to increase the morale of hospital personnel, to improve methods of placement, to lower employee turnover, to promote safety, to lower the cost ratio of insurance, and, whenever possible, to initiate and carry on research germane to the clinical situation.

Is the Concept New?—What makes one hospital more progressive, more far-seeing, and more concerned about its staff than another? This question is not answered by a single social diagnosis. Some administrators have been unexposed to industry's methods of recruiting and retaining personnel with all the adjuvant devices required to build a sense of purpose and a feeling of personal responsibility into the job, such as service pins, incentive award systems, increasing vacations with length of service, channels for grievances, and the symbols of office, be they shoulder patches, uniforms of distinctive color, or name plates on desks.

Perhaps the absence of a tangible visible product gives the employee less with which to identify his labors, and it is difficult to understand or look on "patient care" as the end result of his efforts. The absence of a profit, the lack of a sales record, the missing force of commercial competitiveness—all may create in the minds of the managerial group the belief that a hospital is "different" and requires little of the compensating human relations elements of a profit-making enterprise. But any organization whose function is based primarily on human interaction will have greater need for modern personnel methods than a company engaged solely in distributive activities or raw material procurement. The stereotypes of the hospital staff—the money-demanding business office cashier, the threatening unwelcoming receptionist, the "how are we this morning?" nurse, and the visionless dust-leaving maid—are still in sufficient number in healing centers as to alienate many current and potential patients. Were there no need for considering hospital staffs different from industrial groups, why would such books as "Give and Take in Hospitals," "Diagnosing Human Relations in Organizations—a Case Study of a Hospital," "Human Problems of a State Mental Hospital," "Role Relations in the Mental Health Professions," or "Change and Dilemma in the Nursing Profession," be undertaken, or why would such articles be indicated as "Humanizing Hospitals," "Human Relations in Hospitals," "Keeping Employees Satisfied," "What Nurses Like and Dislike About Their Jobs," or "Workers' Morale Related to Supervisors' Orientation in Human Relations"? That this awareness has been increasing points up the necessity for patterning some of the hospital's methods of operation after the more successful institutions in commerce and industry.

Existing Programs.—Some hospitals have recognized their responsibilities in the area of employee health and have provided facilities for this. Beth Israel Hospital in Boston, St. Vincent's Hospital in New York, Mount Sinai Hospital in Cleveland, Beth Israel Hospital in New York, New Haven Hospital in Connecticut, Wesley Memorial Hospital in Chicago, and the New England Medical Center in Boston are among those which have provided a service under such designations as Personnel Health Service, Personnel Health Clinic, Health Service Department, Employee and Student Health Office, Employee Health Service, or Health Service.

The research committee of the Hospital Personnel Association submitted questionnaires on this subject to 60 members of its organization and received 36 replies, representing 28 New York area hospitals and 8 in New Jersey. Of this group, 34 had employee health programs, most of these offering physical examinations, laboratory tests, emergency care, and health insurance. In 1955, a group of hospitals in Massachusetts was surveyed, and in a 66% return (99 responding out of 150), health services were found to be maintained in 56.

Some institutions have completely divided services, so that one program is offered to students (medical and graduate), another to student nurses, and a third to employees. Frequently, when a hospital is part of a municipal government the employees' health service is a segment of the program provided for city employees. Specialty hospitals require different types of preventive care, so that at the National Institutes of Health, where there is an unusual concentration of potentially hazardous work exposures, the Employee Health Service is tailored to meet the needs of 5,000 investigators and their staffs working in the seven institutes, the hospital, and the four special divisions comprising this large medical research center.

At the Institute of Living, Hartford, Conn., a large psychiatric hospital of 988 employees, 185 of whom reside on the grounds, a personnel physician and a full-time personnel nurse exercise employee health functions. An internist has a comparable assignment at the C. F. Menninger Memorial Hospital, Topeka, Kan. In the Veterans Administration hospitals, centers, and regional offices, employees' health and emergency treatment programs are authorized to foster health improvement measures, and there is assigned a qualified physician to act as personnel physician.

Indications for Health Programs—Occupational Hazards

The needs for medical surveillance in the hospital situation are multifold and relate to the peculiarly built-in hazards of patient care. Specific areas of occupational health risk exist, different from other worksites, with the possible exceptions of laboratory and field research, pharmaceutical manufacturing, and nonmedical radiography. To be considered here are infectious diseases, dermatoses, radiation hazards, and patient contacts and trauma.

Infectious Diseases.—The risk of tuberculosis to medical and nursing personnel has been recognized since 1889, when the high death rate in the Catholic nursing orders in Germany was commented upon by Cornet. In a study of the period 1864 to 1889, he observed that a 17-year-old girl entering hospital nursing died 21½ years earlier than a comparably aged girl in the general population. Tuberculosis was estimated to account for 63% of the deaths among the nursing nuns.

Many groups have been examined and followed up since these early epidemiologic efforts, and longitudinal studies involving large numbers of persons have been in progress for many years. In a study conducted at the University of Minnesota, of 5,304 student nurses who graduated from 1930 to 1951, 15.2% had been infected before admission. Of the remaining 4,497, infections were acquired by 1,020 (22.7%). In the classes from 1930-1942, of the 1,619 who were uninfected on entry 575 (35.5%) developed positive reactions on tuberculin testing. In the 1943-1949 classes, there were 1,876 uninfected on entry, and of these 324 (17.3%) converted. Of 1,002 nonreactors after 1949, 121 (12.1%) converted. All of these had multiple primary lesions; about 3.5% developed clinical tuberculosis; and there were seven deaths.

Experience with U. S. Navy nurses was reviewed for the period 1941-1950,[4] and in this time 100 were admitted for treatment of active tuberculosis. Although the disease was officially accepted as duty-related, the authors were not convinced that infection had occurred during naval service.

An extensive literature survey by Eleanor C. Connolly of the National Tuberculosis Association led to these conclusions in 1950:

> 1. The statement that extremely high infection rates prevail among medical students and particularly among nurses cannot be refuted on the basis of present studies. 2. It is difficult to attribute higher tuberculosis morbidity rates to hospital personnel than to the general population of comparable age because of the diversity of methods employed in determining morbidity. Many authorities writing on the subject, however, believe that tuberculosis represents an occupational hazard for the hospital worker. Tuberculosis case fatality rates among hospital personnel are extremely low. 3. Some studies indicate that persons originally nonreactors develop tuberculosis more frequently than reactors. Other studies show no correlation between ultimate development of tuberculosis and the original tuberculin reaction. Most studies indicate excessive morbidity in a relatively brief period of time after development of a reaction to tuberculin. 4. Responsibility for further control of tuberculosis in the hospital cannot be postponed until future studies of greater scope are made. Such postponement would represent an academic evasion of the problem since certain defects of the environment in many hospitals are already known to exist. The routine x-raying of patients admitted to general hospitals, the maintenance of aseptic techniques, and a rigid policy of routine observation of personnel in an effort to detect early evidence of lesions seem to be three minimum requirements of any control program. 5. Finally, even though morbidity and mortality in hospital groups may be low, tuberculosis must be considered in terms of a chronic disease. Because of the time consumed in treatment, the implications of such a disease are never simple even for the person whose case is uneventful and concludes with recovery. Certainly, the hospital, of all institutions, should utilize every practical means to avoid even one case of tuberculosis.

Brahdy has lamented the lack of control of exposure to tuberculosis in hospitals and has accredited this failure to "insufficient examinations and to faulty case-finding technique." For correction, he advocates an examination program of all hospital employees, dual reading of films, and the designation of one physician as hospital epidemiologist. Those employed in laboratory and hospital mortuary work were observed to experience an attack rate from tuberculosis severe enough to lead to an illness-absence from work three times higher than that for laboratory personnel not exposed.[5]

Tuberculosis as an occupational disease has become the cause of claims before workmen's compensation boards and commissions. As an example of such action, the Superior Court of Pennsylvania, on appeal of a nurse who had developed tuberculosis, pointed out that "the incidence of acquiring tuberculosis among general hospital personnel is higher than that of the general population because such personnel come in contact with unrecognized pulmonary tuberculosis and fail to take the precautionary measures that hospital personnel in tuberculosis sanatoriums take as a matter of routine." The court held that the Occupational Disease Act of that state should be construed liberally in favor of the employee, and the award of the lower court was affirmed.[6] From 1942 through 1955, 90 employees of the Los Angeles County Hospital received compensation for tuberculosis. (The incidence among those exposed, such as physicians, nurses, and laboratory technicians, was six times that of clerical and other nonexposed personnel.) This is costly to hospitals, for it can involve any or all of the payments for work time lost, medical care, death benefits, and funeral costs.

Other infectious diseases appear among hospital employees as occupationally incurred, and these have included Q fever among 47 laboratory workers at the National Institutes of Health. Sulkin and Pike collected data regarding the occurrence of laboratory-acquired infections in the United States, and reported on 1,342 such infections, which involved research institutes, public health laboratories, hospital laboratories, manufacturers of biologicals, agricultural and veterinary schools and experimental stations, colleges and medical schools, and clinical laboratories. The attack rate was 0.5 per year per 1,000 in a population of almost 121,000 estimated to be at risk annually. The types of personnel acquiring disease included trained scientific personnel, animal caretakers, janitors and dishwashers, students (not engaged in research), and others, including clerks, maintenance workers, and visitors. The types of infection were bacterial, viral, rickettsial, parasitic, and fungus.

Since 1943, considerable attention has been given certain aspects of infectious hepatitis and homologous serum jaundice, particularly when these are acquired through accidental transfer via parenteral infusions and immunizations. Hospital employees whose work exposes them to infected blood are subject to these occupational diseases, and 16 hospital workers [7]—blood bank personnel, physicians, nurses, laboratory technicians, and a dentist—were reported as developing homologous serum jaundice while engaged in duties which exposed them regularly to the possibility of accidental parenteral inoculation of blood or its derivatives.

Of tremendous contemporary significance is the incidence of staphylococcic infections in hospitals, with strains resistant to antibiotic therapy. Whereas institutional epidemics in the past have not involved the personnel, these virulent organism strains particularly have produced boils, but without the demarcation usually characteristic of these lesions.[8] These epidemics have become sufficiently widespread as to have led to a Conference on Staphylococcus Infections in the Hospital and Community sponsored by the American Medical Association, held in Cleveland, Nov. 14, 1957, and have been described in hospitals in Pennsylvania, Texas, Ohio, California, New York, and Massachusetts. A high percentage of carriers has been found among hospital workers, and a newly intensified awareness of the importance of environmental cleanliness has been created. In various hospitals, members of the staff demonstrated an incidence of carriage of the predominating strains in mass infections from 6.7 to 17.7%.[9] Langmuir, with some conviction, has stated that the sources of these infections were to be found among the patients and the attendants, including the physicians. He adds, "More subtle and perhaps equally dangerous is the infected but healthy carrier among the attendants."

Dermatoses.—Skin reactions to medicaments and other contactants in the course of professional work have been known for years. With each new material introduced, nurses and physicians—but particularly the former, as they are more frequently engaged in the preparation of the material for the patient—will develop a morbid dermal response to the agent. There have been sensitivities reported to local anesthetics and to antibiotics (including penicillin, streptomycin, and dihydrostreptomycin). To cite one study made in England,[10] 70 local health authorities and 76 chest hospitals and sanatoriums were queried as to the presence of sensitivity reactions of nursing personnel to antibiotics. Reported were 256 workers—a total of 1,470 was at risk—including members of the medical staff, the hospital nursing staff, district nurses, and hospital dispensers, who had developed reactions to streptomycin, penicillin, chloramphenicol, and *p*-aminosalicylic acid. An example of a relatively new agent to be added to the list of dermatogenic medications is chlorpromazine, a strong cutaneous sensitizer, and several case reports have appeared describing the contact dermatitis resulting among nurses, dentists, and pharmacists.

Other agents have led to contact dermatitis in professional persons, such as isoniazid and benzidine. Radiodermatitis is common in physicians, but less of this is being encountered in the more recently trained radiologists and dermatologists.

Radiation.—The introduction of radioisotopes into hospital use has added to the radiation sources of radium, radon appliances, and x-ray equipment to which hospital workers are exposed. Health physics was developed during World War II as a separate discipline to guide workers in radiologic protection. More particularly should these protective measures be extended to hospital personnel other than radiologists, physicists, radioisotope laboratory technicians, and others who are potentially exposed to ionizing radiation. This includes operating room personnel, nurses, nurses' aides who hold or position infants for diagnostic radiography, and dental technicians. Measurements made of exposures received by surgeons and hospital personnel assisting in cystourethrography, cerebral angiography, angiocardiography, femoral arteriography, aortography, cardiac catheterization, bronchography, and similar studies "demonstrated that safety habits were poorly developed in a majority of non-radiological personnel."[11]

The preparation and use of radium and the use of fluoroscopy afford a much greater risk of overexposure to radiologists than diagnostic roentgenography. One radiologist was receiving between 0.2 and 0.5 r per day, and calculations showed that, based on his daily work load, he had received 250 to 500 mr total-body irradiation each day over a period of 20 years. A "routine" blood cell count revealed leukemic cells in his peripheral blood. Barrett,[12] who observed this radiologist, estimated that, in the average case of carcinoma of the cervix with insertion of radium, the following radiation is received: total body, 35 mr; right hand, 150 mr; right arm, 80 mr; fingers of right hand, 200 mr; fingers of left hand, 150 mr; and left arm, 75 mr.

In working with patients who have been administered radioisotopes, Brucer[13] has cited the following exposure values: "The amount of radiation exposure to an attendant remaining close to the bed-side of high dosage patients is considerable. At approximately 1 meter from the patient during the entire course of intra-cavitary gold therapy, over 10 r of 400 kv. radiation was calculated. Hence, a nurse sitting next to the patient could be expected to absorb 1 r of total body exposure in three days. The nurse of a patient treated with 100 mc. of iodine would receive about 1 r of exposure in five days, and with 50 mc. of gallium, the nurse could be exposed to 1 r in about two days."

Exposures, other than therapeutic, exist when pathologists examine the bodies of patients who have received radioisotopes, and specific precautionary measures have been prescribed for those performing autopsies on such bodies, where there may be 5 mc. to over 30 mc. of activity.[14] Personnel monitoring of a dermatology staff in a university hospital has been described,[15] and, in one member, overexposure had been recorded.

With the public apprehension over radioactive fall-out intensifying the concern about exposure to the usual radiation sources—and this "public" includes medical students and hospital workers to a surprising degree—every precaution needs to be taken to insure the minimal exposure required for screening, diagnostic radiography, or therapy, to both personnel and patients.

Patient Contacts and Trauma.—In psychiatric hospitals there is an inherent risk in the daily nursing care situation involving disturbed patients. In a 1,200-bed mental hospital which I had visited as a consultant, the record of injuries sustained by staff members gave evidence of considerable trauma to the personnel. There were 46 injuries in one month recorded involving no loss of time, and, of these, 27 (58%) related immediately to the kind of patient receiving care. In the terminology of the records, these were the notations: struck by disturbed patient, 6; restraining combative patient, 3; packing upset patient, 2; separating fighting patients, 2; struck by patient, 2; struck by resistive patient, 2; attempting to quiet patient, 1; disturbed patient threw wastebasket, 1; dressing disturbed patient, 1; fell when struck by patient, 1; fell while attempting to overtake patient, 1; putting cuffs on patient being held on floor, 1; restraining disturbed patient, 1; restraining patient, 1; taking combative patient to hydrotherapy, 1; and undressing resistive patient, 1—a total of 27.

These were events in an extremely well-run teaching psychiatric hospital—not an establishment redolent of the crudities of bedlam. The statistics released by the United States Department of Labor pointed up the finding that in mental hospitals the injury frequency rate (average number of disabling injuries per million hours worked) is the highest of all hospitals (15.3)—tuberculosis hospitals 11.7, special hospitals 11.3, general hospitals 6.5, and average for all reporting hospitals 8.6. Dr. Winfield Overholser, Superintendent of St. Elizabeth's Hospital in Washington, D. C., has commented on the situation in mental institutions: "The safety and welfare of its patients and employees are of primary concern to St. Elizabeth's and other mental hospitals . . . a meeting was held at the hospital to consider safety measures in the handling of disturbed patients, a small but troublesome fraction of any mental hospital's population. We hope that additional meetings will provide an impetus for further study and consideration of the problems involved, with more effective means to their solution."

The injury frequency rate increases with the size of the hospital but peaks at 13.5 for hospitals with 1,000 to 2,499 employees; in mental hospitals, too, the highest frequency rate of 21.0 is encountered in institutions with 1,000 or more employees.

By operating division, the highest injury frequency is encountered in the plant operation and maintenance division (12.7) and the highest specific area within the professional care division for all hospitals is the nursing service departments (9.1). A distribution by occupation shows these frequencies (per million hours worked): attendants, 19.1; practical nurses, 8.1; nurses' aides, 7.5; orderlies, 7.5; registered nurses, 6.9; and student nurses, 2.3.

The average for this group was 9.1. The greatest number of injuries sustained by nature of injury was in the category "strains and sprains" (33.4), but outstanding was "occupational diseases," which accounted for an injury severity rate (average number of days lost per disabling injury) of 441. Into this group would come occupationally incurred infectious diseases, for example. The hand or finger involved the greatest percentage of all disabling injuries by body part injured (22.0%).

Other hazards productive of injuries to hospital personnel are these: slippery floors, spilled liquids, explosive mixtures from oxygen and the gas or vapor of anesthetic agents, improperly marked exits or entrances, inadequate venting of cooking equipment, volatile solvents in laboratories and electrical repair shops, insertion of glass pipets into corks, sterilizers and autoclaves, lifting of patients, glass ampuls, storage of chemicals, and the use of organic and inorganic insecticides.

The fact that most hospitals are nonprofit organizations has not precluded the administrative problems of workmen's compensation insurance, for hospital employees will file claims with the same alacrity as any other group. For example, a stenographer in a Florida hospital worked in a room where there were two exposed metal pipes and an electric outlet in the floor. Rainfall from a thunderstorm came through the ceiling and settled on the floor. Even though her feet were wet, she continued working, and then lightning struck. She became "paralyzed" and could not remove her hands from the typewriter. There was two months of hospitalization, and the claim was allowed, the court ruling that even if there were no bodily injury the employee did suffer severe shock and mental strain.[16]

In another instance, a nurse, after two months' work in a poliomyelitis ward, acquired the disease. The hospital claimed there was no accident, but the court held that this contention had no validity and that there was a causal connection between the conditions under which the work was required to be performed and the resulting injury claim allowed.[17]

The Physically Disabled Employee

Hospitals have utilized physically limited personnel and have been encouraged to do so by both hospital administrators and those interested in rehabilitation. A study conducted to demonstrate current hospital employment practices regarding disabled persons showed that 86 respondents out of 102 claimed that if the hospital had a lack of applicants for employment then they would willingly hire disabled persons for certain jobs. Responses from 35 nongovernment general hospitals without religious affiliations showed an average of 9.62 disabled employees per hospital, and in 29 which were controlled by religious groups the average was 7.59.

Of 1,003 disabled employees in the institutions studied, 188 were in clinical services, 163 in the housekeeping departments, 111 in the business offices, 107 in the dietary departments, and 96 in maintenance. By type of disability, among 1,047 employees, tuberculosis was first with 41.83%, orthopedic conditions (excluding amputations) 15.09%, cardiac conditions 9.93%, impaired hearing 6.77%, visual impairments 6.30%, mental disorders 6.21%, amputations 3.82%, neurological conditions 2.96%, epilepsy 1.53%, and others 5.44%. The tuberculosis hospitals had an average of 35 disabled employees per hospital, and 86% of these were former tuberculosis patients.

Dr. Howard Rusk has sought the employment of disabled individuals by hospitals and has cited examples of persons with congenital anomalies, gastric resections, laryngectomies, heart disease, diabetes, and stable tuberculosis, as successfully placed in positions, in addition to blind workers. This group is helping to resolve the critical shortage of hospital personnel. A survey of several Catholic hospitals demonstrated that persons with such conditions as amputations, blindness, arthritis, deafmutism, convulsive disorders, hypertension, mental retardation, rheumatic fever, and lower extremity paralyses had been employed and were working capably with "no job adjustment needed."

The reason for throwing light on this employment segment is to point up the facts that these physically marginal persons are filling the job demands, that their activities do not impair their health status, and that physiological, pathological, or senescent changes are appraised and are the functions of an employees' health service. To maintain such a staff in optimal health is not an activity which can be delegated to hospital corridor practitioners; a service must be established for accurate preplacement physical inventories and job adjustment reviews at reasonable intervals thereafter.

Hospitalization Usage

The experience had by hospitalization insurance underwriters in the use of inpatient care facilities by hospital employees is difficult to document. However, the history of one large hospital group which carried this type of coverage for its members and their families is positively known. Because of excessive use, the benefits were lessened, the equivalent of up-rating the premium. Whereas the average number of days per hospital stay, for the period of comparison, for all members of the assured group was 6.4, the hospital employees comprising the subsegment utilized half again as many days per stay, whether they elected to enter their own hospital (i. e., where they worked) or went to other institutions in the community.

No explanation is offered for this except that in the case of teaching hospitals the stay usually is increased. This is mentioned, however, because some control over excessive illness-absence can be exercised by an energetic health service. As all withdrawals from the work scene are costly, the health program, through a good rapport with the employees' physicians, can offer a careful follow-up on return to work. This will permit a shortening of the absence and a saving in man-hours.

Labor Turnover in Hospitals

Personnel directors in hospitals have been aware for years of their elevated turnover rate. This has been explained by the low salaries offered, the increased amount of work per individual employee, the absence of fringe benefits competitive with industry, and the use of hospitals as training areas by persons new to work before moving elsewhere to better paid positions. If one believes in the analytic theory of occupational choice, then one feels that a person enters a profession, craft, trade, or occupation because of unconscious motivating forces. The activities and satisfactions of the job meet the needs —neurotic or otherwise—of the individual, and he finds himself happier doing one kind of work than another.

In any event, to develop a more effective recruiting program for one hospital, emphasis was given to the reasons for the acceptance of hospital positions.[18] A survey of five hospitals in New York revealed the following data: "Among the younger workers responding the average worker spent four years in the hospital field compared to seven years for the 35 to 49 age group and 10 years for the oldest group. . . . However, the average younger worker reports having worked in 2.1 hospitals prior to accepting his present job. The middle age group reports having worked at 3.3 hospitals previously, while the older group reports a history of 2.6 hospital affiliations. Approximately 75% of this oldest group have worked in industry almost 20 years before working in hospitals. They are the old whom industry has discarded." The study of the turnover group showed that the majority of those leaving after short periods had not finished primary school.

To continue to look into reasons for leaving, these were the stated causes for separation: poor attitudes of supervisors and co-workers, 24.2%; shifts and hours of work, 19.4%; number of days of work (five and one-half or more), 17.5%; insufficient help, being overworked, 9.9%; lack of benefits, 8.4%; red tape and disorganization, 5.3%; mental work and poor working conditions, 4.6%; lack of advancement and opportunity, 4.6%; contacts with sick patients, 3.8%; and frustration when patients die, 2.3%.

Although low pay allegedly is the reason for terminating one's employment, this item does not appear among the 10 given. The purpose of citing some of these data is to underscore another indication for the creation and execution of an employee health program. Such an activity, under imaginative and full-breadth direction, can work closely with the personnel department in resolving the problems weighing on employees which will lead to their voluntarily leaving. Through personal counseling or guidance in the seeking of professional help, psychotherapeutic or medical, the worker who feels that the only answer lies in new employment may gain sufficient insight to realize the role of conflict in his proposed move. He may remain and become a more productive and effective staff member.

A health service focused on symptom-relief solely is exercising but a fraction of its therapeutic potential. Through group discussions with management personnel, conferences on the techniques of working with people, and small meetings held in democratic fashion and in a permissive milieu, supervisors can be brought to an understanding of the relationship of their own personality deficits to employee dissatisfaction, high turnover rates, and lowered efficiency. This is a health service in orbit—not a sputtering feeble effort that leaves the launching pad only to fizzle into limbo. There are programs of this quality in industry that should be introduced into the hospital scene.

Essentials of Student Training Programs

Another strong reason for the establishment of employee health services is to aid the hospital in meeting the health requirements as laid down by the A. M. A. Council on Medical Education and Hospitals for the full spectrum of student training categories. With a specifically designed service these obligations can be met. The requirements, as listed, follow.

Internships.—"The hospital should be concerned with the intern's health during his period of service. Each intern should be given a thorough physical examination including a roentgenogram of the chest and routine laboratory studies at the beginning of and periodically as might be indicated during his internship. A member of the attending staff should be assigned the responsibility of acting as personal physician to the interns with a readily available consultation service provided by other members of the attending staff. The hospital should be willing to accept a reasonable share of the responsibility for the continuing care of long-term illness contracted by the intern directly in the discharge of his duties."

Medical Record Library Science.—There are no requirements stated regarding health of medical record librarians.

Medical Technology.—"Applicants shall be required to submit evidence of good health and successful vaccination, and a report of a medical examination should be a part of the students' records. This examination shall include a roentgen examination of the chest. Provisions should be made for medical care and hospitalization, when necessary, for a reasonable length of time. . . . All applicants should be required to submit a physical health report including record of vaccination. All students should be given a medical examination as soon as practicable after admission and this examination should include an x-ray of the chest."

Occupational Therapy.—"All applicants should be required to submit a physical health report including evidence of successful vaccination. All students should be given a medical examination under the supervision of the official school physician as soon as practicable after admission and this examination should include a roentgen examination of the chest."

Physical Therapy.—"It is desirable that qualitative standards with reference to academic performance, character, motivation and health be applied to candidates for admission."

Residencies and Fellowships.—There are no requirements stated regarding health of residents or fellows.

X-ray Technology.—"Applicants shall be required to submit evidence of good health and successful vaccination. All students shall be given a medical examination, as soon as practicable after admission, by a physician designated by the school. This examination shall include a roentgen examination of the chest. There shall be adequate periodic medical examination of the student."

In the report of the Council on Medical Education and Hospitals submitted by members of the House of Delegates of the A. M. A., a revision of the "Essentials of an Approved Internship" and the "Essentials of Approved Residencies and Fellowships" was requested. This will incorporate sections on "selection of interns" and "selection of residents," and in the former it states that "there should be confidence that the interns appointed have the high standards of integrity, motivation, industry, resourcefulness, health and basic medical knowledge necessary to take full advantage of the further educational experience offered." The same statement is made in connection with the selection of residents and fellows. From this it can be seen that additional emphasis is being given to the health status of these graduate students who technically are employees of the hospital.

The Ideal Program

What comprises an effective employee health program? All of the component parts given here need not be considered mandatory for all installations—small hospitals and large—but from those given a selection can be made which will best fit the needs of the institution. These are the elements of an ideal health service.

Estimation of the Work Capacity of Applicants for Work.—The following procedures are done in the preemployment examination: 1. Preplacement medical examination, with taking of medical and occupational histories, appraisal of health status by physical examination, and performance of special examinations. These may include audiometry, visual acuity battery by precision instrumentation, chest roentgenography (a photofluorogram may be taken on all personnel except those previously or currently exposed occupationally to ionizing radiation or those with excessive past exposure to diagnostic or therapeutic radiation—for these, a 14-by-17-in. film should be used), complete blood cell count or hematocrit determination and leukocyte count, urinalysis, serodiagnostic test for syphilis, personality inventory or psychological battery, electrocardiography, feces examination, blood type and Rh factor determination, tuberculin testing, Schick testing for young employees, and other examinations or consultations as indicated. After these are performed, a classification of health status is made as follows: 1, physically qualified for any position; 2, physically qualified for any position, but has minor defects; 3, physically qualified for special employment only, with one or more specifying restrictions, and 4, physically unqualified for position applied for. 2. Matching of physical and emotional capacities of applicant with physical and emotional requirements of job. 3. Interpretation of findings to applicant. 4. Recommendation made to personnel director.

Medical Preparation of Accepted Applicant for Work.—If the applicant is accepted for work, these further steps are taken: 1. Completion of subsequent or additional examination procedures. 2. Interpretation of additional results and need for medical observation or care. 3. Explanation of special occupational health hazards and clinical surveillance needed. 4. Orientation to services offered by employee health service. 5. Initiation of immunization program. This may include smallpox vaccination, poliomyelitis vaccination, typhoid-paratyphoid fever vaccination, tetanus toxoid immunization, diphtheria toxoid immunization (if indicated) for young employees, BCG vaccination (if indicated) for young employees, and influenza types A and B and Asian influenza vaccination. 6. Issuance of wallet card providing information on blood type and Rh factor, drug sensitivity status, medical radiation exposure record, record of immunizing injections, and statement on chronic disease, such as diabetes or convulsive disorder. 7. Issuance of occupational protective eyewear, as indicated by job. 8. Establishment of return visit schedule.

Maintenance and Improvement of Health Status of Employees.—The following procedures are included in the health-maintenance program: 1. Periodic medical reexaminations. These include post-illness, preretirement and prepromotion, reemployment, and annual or biennial examinations and preentrance examinations, if desired, on students in teaching centers. 2. Periodic health interviews and counseling. 3. Special examinations for certain personnel. These are done for executives in the health service or by a private physician, food handlers, radiation workers, laboratory workers exposed to volatile solvents or other toxic agents, and drivers of motor vehicles. 4. Health education program. A program providing for continuing health education may include meetings with groups of employees; procurement, distribution, placement, or showing of health education media (e. g., pamphlets, posters, exhibits, and motion picture films); and orientation meetings with personnel prior to initiation of a new health service activity. 5. Counseling for emotional problems. This may include a diagnostic interview and/or referral to psychiatrist, clinical psychologist, or psychiatric social worker. 6. Counseling for improved job relationships. This may include a diagnostic interview, a conference with the employee's supervisor and the employee, as indicated, and referral to the personnel director. 7. Leading of discussion groups among supervisory personnel in the area of human relations, ways of rectifying impaired work performance, and techniques of working with people. 8. Meeting with groups of managerial personnel for the resolution of administrative or personnel problems.

Medical Supervision of the Work Environment.—A healthful work environment may be maintained as follows: 1. Conducting of surveys for identification—by location, type, and ingredients—of potentially hazardous occupational exposures. This should also include determination of inadequacies in the physical environment, such as impaired illumination and dampness. 2. Determination of ingredients of unidentified but suspected toxic work materials. 3. Obtainment of consultant services of industrial hygienist. Procurement and measurement of samples of work room air often must be done. 4. Preparation and submission of recommendations regarding corrective measures or the installation of industrial hygiene engineering control devices in the form of local exhaust ventilation systems. This is done through joint consultation with an industrial hygienist. 5. Survey of sanitary facilities. This includes waste disposal facilities, sources of drinking water, food preparation areas, and washing facilities for employees. Recommendations on the correction of areas failing to meet accepted standards are then submitted. 6. Consultation with housekeeping department on insect and rodent control. 7. Supervision of ice-making equipment and ice-distributing systems. 8. Maintenance of clinical records. These should document completely all visits made to the employee health service or to clinics, clinical laboratories, the radiology department, and other services, on request or through consultation. 9. Utilization of clinical records. Statistical summaries are made to improve the health status of employees as indicated by epidemiologic interpretation.

Medical Care for Illness and Injury.—Both occupational and nonoccupational illnesses and injuries must be taken into consideration: 1. Occupational injuries. Complete medical care should be given for job-connected injuries, either through the health service or via consultation with specialists on the hospital staff. 2. Occupational illnesses. Complete medical care is also supplied for job-connected illnesses, again, either through the health service or via consultation with specialists on the hospital staff. 3. Nonoccupational injuries. Limited or emergency care will permit the employee, where possible, to finish his work shift. Then referral to local sources of medical care—of the patient's choice—may be made when the condition requires additional diagnostic procedures or prolonged therapy. 4. Nonoccupational illnesses. Again limited care may be given to permit the employee to finish his work shift, and referral may be made to local sources of medical care—of the patient's choice—for conditions requiring additional diagnostic procedures or prolonged therapy.

Services to Management.—Consultant service on the selection and operation of hospitalization insurance or on medical major insurance programs is useful. Consultant service on industrial relations criteria of efficiency—absenteeism, labor turnover, and effective work performance—may also be given.

Comment

Obviously, the limited health service of a small hospital will not have need for the enriched program offered above. All of the major activities, however, of an energetic service have been given, not only for possible inclusion in a new employee health program but also to familiarize program planners with those activities which are to be found in the more productive programs.

The creation of an employee health program in a hospital is a logical step in the provision of a fringe benefit to underpaid and frequently aged and disabled workers. A well-planned and well-executed personnel health program can, through intelligent use of documented clinical records, provide information on the health status of America's hospital employees, including physicians, nurses, paramedical personnel, and clerical, maintenance, and custodial workers. This would provide a solid body of knowledge in place of the current rather thin supply of pertinent information.

With a properly established health service unit, with its own physical facility, its own clinical records, and its especially assigned personnel, the custom of corridor consultations can be eliminated from the hospital scene. Physicians are uncomfortable in attempting—apart from emergency or disaster situations—medical care outside the usual milieu of a consultation room or treatment room. A better service will result with the creation of a health service, and many of the hospital personnel problems can be resolved when an adequate health service is extended to the area of interpersonal relations among hospital employees. Health maintenance of the hospital staff is perfectly feasible, and, when medical practice is removed from the hallway, the rest room, the doctor's lounge, and the lobby, the employees themselves and their supervisors will realize the worth of this progressive step.

A creditable service can be rendered by the general practitioner interested in executing these functions in small hospital installations. The development of a health service for hospital employees is urgently recommended for consideration by all hospitals, medical research laboratories, medical centers (a centralized employee health service can serve individual components of a medical center), and large outpatient clinics, so that this heretofore neglected personnel group can share the advantages of progressive contemporary occupational medicine.

Summary

The hospital industry of the United States, comprising 1,375,000 employees, an annual payroll of 4 billion dollars, and an annual expenditure of 6 billion dollars, offers little to its employees in the way of preventive medical programs at work. The hospital worker—frequently underpaid, older, and physically marginal—has not shared in on-the-job health services as have employees in American manufacturing industry.

The American Medical Association and the American Hospital Association have outlined guiding principles for health services in hospitals which can aid in the creation of occupational health programs. Health services for hospital employees are needed and have been provided in some of the larger institutions of the Northeast, some dating back as far as 20 years. Programs have been encountered in large psychiatric hospitals, Veterans Administration facilities, and research establishments where hazardous work exposures exist.

The needs for medical surveillance in the hospital situation are multifold and relate to the built-in hazards of the operation of patient care. These hazards include infectious disease (tuberculosis, Q fever, homologous serum jaundice, staphylococcic infections, and other bacterial, viral, rickettsial, parasitic, and fungus disorders), contact dermatoses, ionizing radiation, and patient-induced trauma and other injuries. Occupationally incurred illnesses and injuries have led to the presenting and contesting of claims before workmen's compensation boards and commissions.

The utilization of physically disabled employees in hospitals indicates further the need for a health service to assure accuracy in their placement and job adjustment. There is some evidence to indicate that hospital employees overuse hospitalization insurance, and a health service could exercise some control in this area.

Because of a high labor turnover in hospitals, an imaginative employee health program could study the reasons for voluntary separation of employees and, through close liaison with the personnel director and the managerial staff, endeavor to identify the causes of excessive turnover. Through group discussion or individual counseling, it could lower this costly budget item.

The A. M. A. Council on Medical Education and Hospitals has outlined specific health requirements for interns, medical technologists, occupational therapists, physical therapists, and x-ray technicians, and the presence of a health service would allow compliance with these requirements.

An ideal program is built in the general areas of (1) estimation of the work capacity of applicants for work, (2) medical preparation of accepted applicants for work, (3) maintenance and improvement of the health status of employees, (4) medical supervision of the work environment, (5) medical care for illness and injury, and (6) services to management.

THE PROBLEM BACK

John E. Kirkpatrick, M.D., San Francisco

Pain in the back is the most common single reason given for occupational disability, and it is generally ascribed to actual injury to the vertebral column. The workman does not have to have any witnesses; he may neglect to report an occurrence to his employer, or he may think back to some indefinite date within one year to establish the basis for a claim of a work injury. An individual educated in legal and medical matters by such an experience may become a repeater, and for some this becomes a way of life. None of the rheumatic diseases have ever been created by slight or severe mechanical trauma in experimental animals or human beings. Many improbable medical decisions have been made by lay commissions in ignorance or disregard of this fact. It is believed that closer study and more precise diagnosis of back complaints will alter the statistics in this branch of occupational medicine.

The effect of significant actual trauma on the back is not difficult to diagnose, and the treatment is well standardized, whether medical, surgical, neurological, orthopedic, or a combination of these. Temporary aggravation of preexisting back conditions or emotional attitudes is a topic for another essay and is purposely omitted.

Factors in Trauma to the Back

One example of significant trauma should suffice to illustrate this: Suppose a fracture of lumbar transverse processes occurs in which the continuity of the bone is disrupted, the lumbar muscles and ligaments attached thereto are torn and disrupted, and, often, a palpable hematoma forms. Here then is severe spinal trauma.

What is the expected course of tissue repair? It progresses steadily toward healing with restoration of continuity of bone, muscles, and ligaments. Some scar tissue may form to complete the restoration of continuity. After an injury of this kind, it is possible to predict an end to the disability. Here is a severe injury of the back which does not result in chronic traumatic myositis, fibrositis, arthritis, or granulomatous inflammation.

If, in addition, a spinal joint is torn asunder, then a traumatic arthritis may, and often does, result. It should be pointed out that it takes severe and obvious actual trauma to disrupt a spinal joint, and it is usually demonstrable by x-ray. Similarly, severe trauma is necessary to cause a disruption of a healthy normal spinal muscle or ligament, either in continuity or from its attachments. The course of traumatic arthritis of a disrupted spinal joint is toward healing by bony bridging and ankylosis, not toward further deterioration and chronicity.

Let us consider the dogma of "wear and tear," so-called microtrauma, as a cause of osteoarthritis of the spine. All normal human beings walk erect and use the spine daily in a multiplicity of ways. This disease affects women about three times as often as men and appears in the latter years of life; it does not affect the entire human race, but only about 7 to 10%. It is not found any more often in one type of occupation than in another. The cause is still unknown, and although it will be discovered someday it will not be found to be due to microtrauma, or wear and tear. No one has ever reproduced it by actual mechanical trauma either in experimental animals or in man.

Some of the more common forms of rheumatic diseases which affect the spine during the years of employment are fibrositis, myositis, bursitis, gout, and rheumatoid spondylitis. Even these affect only a small percentage of the 11 million Americans who are afflicted with arthritis and related rheumatic diseases. Some of these conditions run a course independent of treatment, and some of the effects of these diseases are reversible without treatment. Most of them have a tendency to recur at more or less frequent intervals.

Causes of Chronic Back Disorder

The so-called problem back occurs most often when the element of chronicity arises. A case of this kind must have its inception with the first visit to the physician. The history of the occurrence related by the patient may sound plausible, and too often the physician makes no effort to find out the body mechanics and physical effects of the occurrence which could have a bearing on the patient's complaints. The patient has made his diagnosis already on the basis of what he believes happened and why he has symptoms in the back. Almost in the next breath the physician tells him that he has "strained his back," and if the patient should state that he has a pain radiating down one of his legs the doctor is quick to add that he "must have a disk." The conclusions of the patient, and of the doctor, are then quickly transferred to a Doctor's First Report of Work Injury blank and sent to an insurance company. No matter what is found in the future to controvert this original document, it is always staring one in the face during the period of litigation.

Read in the Symposium on Occupational Medicine for the Private Practitioner before the Section on Preventive Medicine at the 107th Annual Meeting of the American Medical Association, San Francisco, June 24, 1958.

In the absence of a reasonable or provable description by a patient of a significant traumatic incident, after adequate questioning about the physical and mechanical details of the alleged accident or occurrence it is important to know if any similar symptoms have been noted by the patient prior to this occurrence, if he has received any prior compensation or award of disability for back trouble, or if prior treatment for back symptoms has been given. The patient's work history, social and economic background, and his mental attitude toward the incident are important to discover.

When back symptoms with prolonged disability occur, the initial quick diagnosis of "acute back strain" becomes suspect. Chronic back complaints are most commonly due to disease, structural abnormality, environmental conflicts, emotional attitudes, or a combination of one or more of these conditions.

What, then, does one look for in a patient who states he felt a pain in his back while doing work in which he has been engaged regularly for months or years? It is a human trait to believe that pain is caused by some act that is being performed or by some act that has been performed in the past and thought back to as a likely cause. The patient philosophizes that there was never anything the matter with his back before, so why should there be now, and arrives at his own diagnosis that it must have been caused by the incident. It would never occur to him that there could be an intrinsic cause for his pain. It is here that the doctor can make his first mistake and go on record as substantiating the patient's description of the occurrence, as well as agreeing with the patient's diagnosis.

Here we find the primary element of a wrongful claim: a quick, totally inadequate history accepted without any attempt to determine if any significant actual trauma did occur which could cause the complaints.

Some of the most common reasons for this situation can be as follows: economic factors, in which both the patient and his doctor are involved; antagonism, such as belief that the boss does not like him; anxiety, or fear of losing his job; laziness, with unemployment insurance to fall back on, or a wife who can work or is working; health and welfare fund pressure, including actions to keep the fund from bearing any expense which can be shoved off on to workmen's compensation carriers; antisocial factors, as belief that the economic system is against him and, paradoxically, owes him a living; psychic factors, such as a true or malingering hysteria; or desire to appear a hero, as after an accident where the patient describes how he helped to save other workmen from injury, thereby injuring himself, or saved a piece of valuable machinery by injecting himself into the situation in the "nick of time," saving the machine but injuring himself.

Compensation Factors

During the recent 50 years of the industrial age, monetary compensation for disability has been broadened progressively to cover any symptom a workman may have if he can think of an occurrence or exposure. The workman does not have to have any witnesses; he may neglect to report an occurrence to his employer, or he may think back to some indefinite date within one year to establish the basis for a claim of a work injury. During this industrial era, and before unemployment compensation disability welfare plans and private health insurance plans were so widespread, a traumatic etiology concerning back symptoms was progressively promulgated by labor management and tacitly supported by a quick medical report without a detailed study of the case, with the worker awarded compensation by a lay commission.

There have been so many improbable medical decisions made by lay commissions during this era that now, when almost every workman is covered by health and welfare insurance, it is a running battle between industrial insurance carriers and health and welfare carriers to place the blame for the problem back. During the legal delay, the patient has become confused, is penalized by an unjustifiable wage loss, suffers a progression of untreated diseases, develops personality and social disorders, and becomes almost impossible to rehabilitate.

When such a case eventually becomes a matter for an award of permanent disability, the monetary gain does not always effect a cure. Such an individual, after being so well educated in legal and medical matters, often becomes a repeater, and, for some, this becomes a way of life. One such experience often makes him aware of the fact that, after litigation is all over, he did not have a traumatic injury after all and now all he has to do to get paid for a few weeks off from work is claim his back hurts as a result of some trivial incident on the job, regardless of whether he has proof of this occurrence. Soon he has another claim on the way based on recurrence, aggravation, or exacerbation of a preexisting disability.

Summary and Conclusions

None of the rheumatic diseases—fibrositis, myositis, bursitis, gout, rheumatoid spondylitis, rheumatoid arthritis, and osteoarthritis—have ever been created by slight or severe mechanical trauma in experimental animals or in human beings. Recent surveys reveal that 7 to 10% of the population of the United States is afflicted with these diseases. These diseases are associated with dysfunction of the reticuloendothelial system, often with the development of granulomatous inflammations in the musculoskeletal system in response to specific inanimate (chemical or physical) agents, the more common being collagen, rheumatoid factor, cholesterol, and uric acid, singly or in mixed lesions.

The fact that an alleged accident brings a patient to the physician and after physical examination he is found to have one of these diseases should not influence the physician to pass up the opportunity to do him a worthwhile service by making an accurate diagnosis and so informing the patient, instead of reporting a claim of an alleged occurrence as being the reason for his back complaints and disability.

If a proper diagnosis of back complaints is made, I believe the statistics in regard to back injury in California will be altered. At the present time, in California, one-fifth of all cases of lost time are alleged to be due to back injury. It is the most common single cause of disability and loss of productive capacity.

The effect of significant actual trauma on body tissue is not a mystery insofar as its course is concerned. The course of recovery from a simple bruise or a major disruption of body tissue, except the central nervous system, progresses toward healing, resulting either in complete restoration of function or in some residual impairment of function by deformity or scar tissue, but without recurrence. Trauma does not produce a persistent stimulative effect on the cells of the reticuloendothelial system. The course of the granulomatous inflammation is toward chronicity and recurrences. These lesions may be reversible, may end in scarring, or may cause total progressive dissolution of tissue or total destruction of the individual.

516 Sutter St. (2).

HAZARDS OF THERAPY IN RESPIRATORY DISEASE

William B. Sherman, M.D., New York

In the treatment of obstructive pulmonary emphysema and bronchial asthma it is important to avoid certain procedures that may further handicap respiratory mechanisms already on the verge of exhaustion. Persistent respiratory insufficiency is in itself a dangerous state. Drugs that reduce anxiety, relieve insomnia, and suppress coughing may be physiological luxuries which the patient cannot afford; they must be chosen with care and given in small or average, rather than large, doses. Profound narcosis with any drug is dangerous in severe asthma or in emphysema complicated by respiratory infection. For cyanosis the rational therapy is oxygen, but patients receiving it must be watched closely for signs of carbon dioxide narcosis. Violent reactions to penicillin or even to such simple drugs as aspirin are especially likely in patients with asthma and may occur in many patients with emphysema. Patients with these diseases urgently need treatment directed at the underlying condition.

Since space permits discussion of only a few aspects of respiratory disease, I shall devote it primarily to the hazards involved in the treatment of respiratory insufficiency as seen in obstructive pulmonary emphysema and bronchial asthma. These two diseases exemplify well some of the problems peculiar to the respiratory system.

Respiratory Insufficiency

In both asthma and emphysema, the respiratory defect is ventilatory; obstruction of the air passages and loss of normal elasticity of the lung prevent adequate flow of air to and from the alveoli. The respiratory insufficiency of emphysema becomes acute during respiratory infections, when the increased secretions further block the already inadequate airways. In asthma, the obstruction is due in part to spasm of bronchial muscle and edema of the mucosa, but in those cases that terminate fatally, the most obvious pathological lesion is widespread plugging of the smaller bronchi and bronchioles by tenacious mucus.

Under these conditions of disease, the natural protective and adaptive mechanisms of the respiratory system become inadequate and themselves play a large part in the symptoms of the patient. The increased respiratory stimulus as the respiratory center strives to compensate for inadequate aeration of the blood is manifested as distressing dyspnea, which prevents sleep and keeps the patient in a state of restless anxiety. The cough, less effective because of decreased air flow, is unable to dislodge the overwhelming accumulation of secretions and itself often contributes to the dyspnea.

Persistent respiratory insufficiency due to emphysema complicated by acute infection, or to status asthmaticus, is a dangerous state. The fact that the

---

From the Department of Medicine, Columbia University College of Physicians and Surgeons.

Read in the Panel Discussion on a General Review of the Hazards Encountered in the Use of Certain Therapeutic Agents before the General Scientific Meetings at the 107th Annual Meeting of the American Medical Association, San Francisco, June 24, 1958.

patient has previously recovered from similar attacks usually leads all concerned to a false sense of security, and rapidly fatal respiratory failure may leave the physician surprised and the family unaware of the danger. Patients with these diseases urgently need treatment directed at the underlying condition; measures which merely relieve the symptoms often do so at the expense of suppressing the already inadequate protective mechanisms and may actually increase the danger of respiratory failure.

Use of Drugs

Most of these patients require sedatives, particularly when sleep is impossible and restlessness is increasing the oxygen need. As an adjunct to more fundamental treatment, they are of considerable value. However, their use involves two related hazards: (1) the depression of the already fatigued respiratory center and (2) the possibility that the *exhausted and sedated patient may be suffocated* by his own secretions. The first risk depends on the choice of drugs, the second on the doses used.

The most effective drug for the relief of dyspnea and anxiety is morphine. However, its efficacy results largely from marked depression of the respiratory center and partly from a false sense of well-being. The only local affect on the bronchi is an unfavorable one of increasing muscle spasm. It is as dangerous as it is effective, and, the more serious the condition of the patient, the greater is the danger. No doubt its use in the past has contributed to a fatal outcome in many cases of asthma. Several authors have suggested that it is the principal cause of death in asthma. However, avoidance of its use has not solved the problem, and other sedatives are not entirely free of risk.

With the increasing reluctance to use morphine in asthma, meperidine (Demerol) hydrochloride has become popular as a substitute. Pharmacological studies suggest that its use is more rational. The depression of the normal respiratory center is considerably less than with morphine, and some relaxation of spastic bronchi may be expected. In severe status asthmaticus, it is occasionally useful, when used sparingly in conjunction with drugs relieving bronchial obstruction, but it should not be used as the sole treatment. In some cases, two or three doses of 50 mg. each in the course of a few hours have produced serious respiratory depression and, occasionally, apparently contributed to a fatal outcome. When such respiratory depression is observed, it can usually be combated effectively by intravenous injection of nalorphine (Nalline) hydrochloride.

In acute asthmatic attacks of short duration, meperidine can be used with little risk of respiratory failure. However, in these milder cases caution should be observed because of the danger of habituation. Asthma is important among the diseases in which treatment leads to addiction.

There are many sedatives which can be used in ordinary doses without significant risk of respiratory depression. The barbiturates and chloral hydrate are the most frequently used; paraldehyde, alcohol (ethanol), and ether by rectum are relatively safe in regard to respiratory depression but are open to other objections. The various tranquilizing drugs are also valuable and relatively safe.

Any of these sedatives should be given in small or average, rather than large, doses, with administration repeated carefully as necessary to produce relaxation and light sleep. Profound narcosis with any drug is dangerous in severe asthma or in emphysema complicated by respiratory infection.

Deaths from asthma which follow the use of barbiturates are usually due to gross overdosage based on a misconception of the nature of the illness. As the patient fails to respond to the usual drugs and becomes increasingly tense and anxious, the psychosomatically minded physician may become convinced that the emotional state is producing bronchospasm through a neurogenic mechanism and that *release of tension is the most pressing problem.* Because of the obvious seriousness of the condition, large doses of amobarbital (Amytal) sodium or phenobarbital (Luminal) sodium are injected intravenously in a heroic effort to eliminate the emotional factor. Unfortunately, the patient with this type of asthma is suffering more from an accumulation of mucus secretions than from bronchospasm and, in his anesthetized state, dies from asphyxia without further efforts to expel the obstructing material. Like any drowning man, he cannot afford the luxury of sound sleep until the danger is removed.

What has been said of general sedatives applies to some degree to the inhibition of cough. While frequent cough may be distressing and ineffective and may aggravate the dyspnea, it is basically a protective mechanism and mitigation with small doses of codeine or milder agents is preferable to complete suppression.

Need for Oxygen

In severe respiratory insufficiency, oxygen is often needed for the relief of cyanosis. When the anoxia is severe and of long standing, even this rational form of therapy involves some risk, more often in emphysema than in asthma. The anoxia in such cases is usually associated with carbon dioxide retention. As the condition persists, the respiratory center becomes less sensitive to the carbon dioxide tension of the blood and the stimulus for respiration depends largely on oxygen lack. As this oxygen deficiency is corrected by therapy, the respiration is depressed and the carbon dioxide level continues to rise. When this level reaches 85-100 vol. %, the carbon dioxide has a narcotic affect and coma ensues. An already elevated carbon dioxide tension at the beginning of treatment gives warning of this hazard. If facilities for blood carbon dioxide analysis are not available, patients with severe and prolonged anoxia should be watched carefully when oxygen treatment is begun.

This carbon dioxide narcosis may be prevented or corrected by administration of oxygen with a positive-pressure respirator, which serves to maintain adequate pulmonary ventilation so that carbon dioxide is eliminated as oxygen is taken up.

Comment

The hazards involved in the use of steroids will be discussed elsewhere. In respiratory disease, particularly bronchial asthma, when the steroids are used for periods of only a week or two the hazards have proved to be far less than was feared a few years ago.

In regard to the use of antibiotics, especially penicillin, the hazards are increasingly apparent. The incidence of severe anaphylactic reactions to penicillin is unusually high in allergic and asthmatic patients. Also, the development of this type of sensitization is apparently greater after sporadic injections at intervals of weeks or months, which are often utilized in the treatment of recurrent asthma or bronchitis.

Finally, it should be remembered that patients with asthma and many of those with emphysema are allergic persons who may have violent allergic reactions to such simple drugs as aspirin.

GASTROINTESTINAL HAZARDS ENCOUNTERED IN THE USE OF CERTAIN THERAPEUTIC AGENTS

GENERAL REVIEW

Gordon McHardy, M.D., New Orleans

The gastrointestinal tract is exceptionally susceptible to untoward reaction to certain therapeutic agents. Considerable evidence has been presented to indicate that the clinical picture of acute intrahepatic obstructive jaundice results from certain agents commonly used in gastrointestinal dysfunction and disease. The inference is that wide usage, which condones the risk of hepatotoxicity, is unfortunately prevalent. Stimulation of the appetite by iproniazid does not justify risking hazardous dosage. Approximately 76% of the population of the United States have been treated with antibiotics. The superinfection from disturbance of the normal bacterial flora permits emergence of pathogenic organisms. The resultant severe pseudomembranous enterocolitis, if not suspected and properly managed, is often fatal. Other untoward gastrointestinal reactions observed include atypical anticholinergic-induced achalasia, esophageal obstruction resulting from bulk laxatives, esophagitis from antibiotics, acid-base imbalance from intensive antacid therapy, gastritis from gastric irradiation from duodenal ulcer, and carbohydrate-induced dumping syndrome.

The most widely used and probably most effective therapeutic agents today have been responsible for dramatic gastrointestinal reactions that have introduced new entities into the medical literature. Thiazine-induced cholostatic jaundice,[1] antibiotic-resistant staphylococcic pseudomembranous enterocolitis,[2] and steroid-activated or steroid-produced peptic ulcer[3] have each offered frustrations to the therapist whose healing agent boomeranged so as to produce another illness.

The gastrointestinal tract is exceptionally susceptible to untoward reaction to certain therapeutic agents.[3] Often, the drug has a specific gastrointestinal indication; in other instances, the reaction of the digestive tract has been used as an index of toxicity or of effective dosage, as, for example, in the case of digitalis, colchicine, or atropine. The present discussion will be limited to the more significant and more frequently encountered hazardous gastrointestinal reactions to agents of definitive therapeutic value in the field of gastroenterology. These agents have been classified according to two gradations of severity. Among the more hazardous have been included those agents whose effects persist after discontinuance of the therapy and excretion of the drug; these are associated with appreciable illness and potential death (table 1). The less severe reactions have been classified as symptomatic hazards, since the untoward reaction subsides on withdrawal or excretion of the drug; illness is minimal, and death is probably never a direct result (table 2).

Read in the Panel Discussion on a General Review of the Hazards Encountered in the Use of Certain Therapeutic Agents before the General Scientific Meetings at the 107th Annual Meeting of the American Medical Association, San Francisco, June 24, 1958.

Severe Gastrointestinal Therapeutic Hazards

Jaundice.—Considerable evidence has been presented to indicate that the clinical picture of acute intrahepatic obstructive jaundice results from two agents commonly used in gastrointestinal dysfunction and disease. Jaundice accompanied by an elevated level of alkaline phosphatase in the serum, negative result of serum flocculation tests, and evidence of bile thrombi and lymphocytic infiltration of the portal tracts on needle biopsy of the liver is considered the result of direct toxic action of arsenic on the intrahepatic biliary ducts—perhaps a sensitivity reaction to chlorpromazine. The exact pathogenesis of the jaundice due to chlorpromazine has not been established. Additionally, promazine and prochlorperazine have been indicated as icterogenic agents. Reports of iproniazid-induced hepatic involvement have added another complexity.

TABLE 1.—*Severe Therapeutic Gastrointestinal Hazards*

Manifestation	Agent	Indication
Jaundice	Chlorpromazine	Sedation
	Iproniazid	Stimulation of appetite
	Arsenicals	Amebiasis
Enterocolitis	Antibiotics	Colonic infections Amebiasis Preparation of intestine
Ulcerogenic disturbances		
Hemorrhage	ACTH	Ulcerative colitis
Perforation	Adrenal steroids	Hepatic disease Collagen diseases
Serum hepatitis	Needle	Parenteral therapy
	Blood	Replacement of blood

The agents responsible for this reaction are not therapeutically essential. Other amebicides are as effective as the arsenicals, which, fortunately, are not widely used. Antiemetic agents without the thiazine radical are available. Chlorpromazine, however, is reputed by its manufacturer to have reached over 10 million patients in the United States alone, the inference being that such wide usage condones the risk of hepatotoxicity. Stimulation of the appetite by iproniazid (Marsilid) does not justify risking hazardous dosage.

Enteritis.—Approximately 76% of the population of the United States has been treated with antibiotics, and in 9% a resistant organism has developed.[4] Enterocolitis[5] from antibiotic-induced staphylococci (micrococci) may be manifested merely by diarrhea, produced by elaboration of the enterotoxins, or it may progress to severe enterocolitis and occasionally to fatal fulminating episodes of pseudomembranous ulcerative colitis. Bacteriological studies have established the presence of staphylococci resistant to the antibiotic used as the pathogen; these have been found after use of almost all the antibiotics. The superinfection from disturbance of the normal bacterial flora permits emergence of pathogenic staphylococci. The resultant severe pseudomembranous enterocolitis, if not suspected and properly managed, is often fatal.

This induced illness could be considered a necessary evil if antibiotics were used only when adequately indicated. Effort should be expended toward its prevention by cautious use of these drugs and by close observation during their administration to detect resistant organisms before the reaction becomes severe.

Ulcerogenic Agents.—Development or activation of peptic ulcer, with its complications of hemorrhage and perforation,[6] has occurred too frequently during administration of ACTH, the adrenal steroids, and the Rauwolfia compounds to be considered merely coincidental.[7] This hazard seems greater with the steroids. Gastric hypersecretion, adrenocortical hyperfunction, and lowered tissue resistance have each been incriminated as the mechanism, but careful appraisal has failed to establish the precise ulcerogenic effect of these agents.

The exact relationship of the development of ulcer to the medication, the mode of pathogenesis, and the true frequency as compared to the over-all incidence of peptic ulcer are difficult to determine. Yet, the prevalence of reported, as well as unreported, cases forbids our disregarding the obvious dangers inherent in indiscriminate, unduly prolonged, and excessive administration of the steroids. Prophylactic measures to control gastric hyperacidity should be used whenever administration of steroids is indicated.

Only infrequently, and then with larger doses of the Rauwolfia compounds, has significant gastric hypersecretion occurred with ulcerogenic possibilities. Rauwolfia-induced hypersecretion[8] has been attributed to local action, endogenous secretion of histamine, and central suppression of inhibitory sympathetic neural impulses.

TABLE 2.—*Symptomatic Therapeutic Gastrointestinal Hazards*

Manifestation	Agent	Indication
Fungal infection .... (moniliasis, stomatitis, esophagitis, anoproctitis)	Antibiotics	Colonic infections Amebiasis Preparation of intestine
Salmonellosis activation	Antibiotics	Colonic infections Amebiasis Preparation of intestine
Gastric hypersecretion..	Rauwolfia compounds	Sedation
	ACTH	Hepatic disease
	Adrenal steroids	Ulcerative colitis Collagen diseases
Delayed gastric emptying	Anticholinergics	Peptic ulcer
Masked hemorrhage and perforation	Anticholinergics	Peptic ulcer
Paralytic ileus	Anticholinergics	Peptic ulcer
Constipation	Anticholinergics	Peptic ulcer
Impaction	Barium	Diverticulosis
	Bulk preparations	Constipation
Vitamin deficiency	Antibiotics	Intestinal infection Amebiasis Preparation of intestine
Nausea and vomiting...	Sulfonamides	Intestinal infection
Biliary dyskinesia	Opiates	Pain

Serum Hepatitis.—Viral serum hepatitis is identified with the syndrome of serum hepatitis that develops six weeks to six months after parenteral inoculation of virus-contaminated blood or its products or after use of a contaminated needle.[9] Transfusions are frequently given to patients with gastroenterologic complaints in whom acute and chronic loss of blood necessitates replacement. Every effort should be made to exclude blood donors who represent potential vectors. Unnecessary transfusion should be avoided, and parenteral equipment should be carefully sterilized.

Symptomatic Gastrointestinal Therapeutic Hazards

Fungal Infections.—Still extremely divergent are opinions [10] regarding the pathogenicity that usually results from organisms indigenous to man wherein lowered resistance due to altered bacterial flora by antibiotic therapy permits invasion by Candida albicans, Aspergillus, Penicillium, Cryptococcus, and Geotrichum to result in intensive involvement of the tongue, buccal mucosa, pharyngeal esophagus, and perianal area. Nystatin [11] may be an effective prophylactic and therapeutic antifungal agent, but I have found undecylenic acid, local measures, anesthetic agents (procaine), anti-inflammatory solutions (steroids) with dilute iodine to be more efficient.

Activation of salmonellosis has been reported as a complication of the use of tetracycline, to which most strains of Salmonella are relatively resistant.[12]

Gastric Hypersecretion.—Gastric hypersecretion may occur during excessive, prolonged, or parenteral administration of Rauwolfia compounds in the sensitive patient.[13] That hypersecretion ever results from administration of ACTH or adrenal steroids has been debated.[3] In any event, since the use of both agents has been associated with hypersecretion they are best avoided in the presence of peptic ulcer and its complications.

Delayed Gastric Emptying.—Delay in gastric-emptying, as a result of anticholinergic-induced decreased gastric motor activity, may become clinically significant in the presence of partial pyloric obstruction,[14] wherein retention produces a vicious cycle of retention-stimulated gastric secretion. This has also been observed with belladonna alkaloids.[15] Judicious use of these agents should prevent such occurrence. Large doses, however, in the absence of pyloric disease, have resulted in retentive phenomena.

Hemorrhage or Perforation.—Hemorrhage from a peptic ulcer may occur during anticholinergic therapy and defy recognition. Hemorrhage may be concealed when the expected vasomotor response to the vagal-acting drug is misinterpreted but is actually the result of loss of blood. Perforation may also ensue, but the pain may be eliminated as a premonitory sign of this complication. Although unusual, these complications occasionally develop. Furthermore, protracted bleeding has been observed after continued use of anticholinergics during bleeding episodes.

Paralytic Ileus.—The paralytic ileus, accentuated by administration of anticholinergics during treatment of acute pancreatitis, may inhibit motility to a disturbing degree in the preoperative and postoperative periods. This disturbance, with associated curtailment of motility and inhibition of gastrocolic and defecation reflexes, has produced a significant degree of constipation and, at times, severe impaction.

Vitamin Deficiency.—Vitamin deficiencies are most likely to occur in patients who have received prolonged antibiotic or sulfonamide treatment, which reduces intestinal bacteria that normally produce vitamin K and several members of the vitamin B-complex group. Significant hypoprothrombinemia may be a true hazard should the chemotherapy be a preoperative measure for colonic resection.

Nausea and Vomiting.—Nausea and, occasionally, vomiting have resulted from administration of sulfonamides.[16] Abdominal pain as the result of administration of chlorpromazine has also been reported.[17]

Biliary Dyskinesia.—During administration of opiates, biliary dyskinesia and suppression of hepatic function, with delayed metabolism of opiates by a diseased liver, are often overlooked hazards of these drugs in the preoperative and postoperative periods in the patient with jaundice.

Other Hazards.—Other untoward gastrointestinal reactions observed include atypical anticholinergic-induced achalasia, esophageal obstruction resulting from bulk laxatives, esophagitis from antibiotics, acid-base imbalance from intensive antacid therapy, gastritis from gastric irradiation for duodenal ulcer, and carbohydrate-induced dumping syndrome. Dietary carotenemia probably has little significance if not erroneously diagnosed as jaundice. Diarrhea is not an unusual consequence of most antihelminthic measures. Obstruction as a result of energetic treatment for ascariasis is a severe and, at times, fatal reaction.

Such diuretic aids as the various carbonic anhydrase inhibitors, the ammonium resins, and ammonium itself are hazardous in impending hepatic coma, as are efforts to enforce a high-protein diet. Development of pancreatitis during administration of adrenocortical hormones has been an objection to steroid treatment of pancreatitis. Diverticulitis has also been observed as a fairly frequent complication of antibiotic therapy. Mineral oil has been said to affect absorption of vitamin A.

Therapeutic procedures, such as indwelling duodenal tubes, have resulted in erosive esophagitis; the Sengstaken-Blakemore tube has precipitated esophageal ulceration; and the Miller-Abbott tube, improperly inflated, has caused pressure necrosis, with perforation, in the small intestine. The esophageal dilator has sometimes perforated the esophagus.

Summary

The high efficacy of many gastroenterologically applicable therapeutic agents is marred by toxicity. Adequate evaluation of therapeutic demand should precede the use of agents recognized as hazardous so as to preclude the indictment of doing more harm than good. Knowledge of such side-effects and the ability to recognize and cope with them intelligently are as essential as recognition of indication, mode of administration, and dosage.

ESOPHAGEAL CYTOLOGY BY A GAUZE-SPONGE SMEAR TECHNIQUE

Lee M. Hershenson, M.D., Virginia Lerch, M.A.
and
Morris A. Hershenson, M.D., Pittsburgh

For cytological examination of the esophagus, a small piece of gauze is rubbed past a suspected lesion by means of an esophageal dilator introduced over a rubber-tipped guide wire. Smears made from the material thus obtained contain large numbers of well-preserved cells. This facilitates accurate differentiation of benign from malignant lesions, since the probability of finding tumor cells in a case of cancer depends on the total number of cells sampled and correct identification requires cells in a well-preserved state. Except where esophageal varices are suspected, this method appears to be safe. No complications were encountered, and diagnostic accuracy was high.

Cytological methods of examination have well-established value in the confirmation of clinically or radiologically suspected malignancy of the esophagus. They are safer and more convenient than biopsy through the esophagoscope and have in some instances even a greater accuracy. Not always, however, is adequate cellular material obtained by the usual lavage procedure. A technique that is consistently productive of more well-preserved mucosal cells should increase the reliability of this important diagnostic tool.

Earliest attempts at cytological diagnosis of esophageal lesions were made with smears of secretions aspirated at esophagoscopy, but frequently these gave only scanty or degenerated cells. The technique now most widely used consists of introducing a Levin tube through the nose or mouth until the tip just passes the esophagogastric junction or encounters an obstruction, then having the patient swallow several hundred milliliters of saline solution while aspirating at the same time from the tube, and making smears from the centrifuged sediment of the wash solution thus recovered. With this method several investigators[1] have reported near-

---

From the departments of medicine and pathology, the University of Pittsburgh School of Medicine and the Presbyterian and Woman's hospitals.

perfect accuracy in small groups of cases, and in another study[2] 50 of 53 cases of esophageal cancer were correctly diagnosed. In the largest series of patients examined by this method, a positive diagnosis of malignancy was made in 103 of 148 cases (69.6%) of primary esophageal neoplasms.[3] These latter authors emphasized that in most cases the malignant cells were few, to be found only after laborious screening of the slides, and that the absence or extreme scarcity of tumor cells was the usual cause of incorrect negative interpretations. They found, on the other hand, three false-positive diagnoses in 135 benign cases.

Several methods for improving the quality of the cytological material have been proposed. Smears have been made from secretions wiped off esophageal bougies after their use for therapeutic dilatation and from bits of gauze tied around the end of a Levin tube and passed down the entire length of the esophagus or to the point of obstruction.[4] A foam-rubber swab attached to a wire handle has been devised and found to give much better material than the lavage technique.[5] Good results have been reported with smears made from cotton or gauze swabs rubbed over a lesion under direct observation through the esophagoscope.[6] That procedure sacrifices convenience, but the specimens obtained are said to contain abundant cellular elements, frequently well-preserved sheets or masses of cells with histological detail intact.

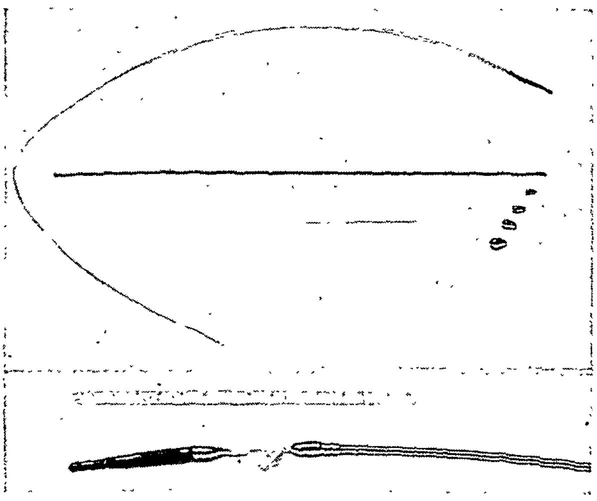

Fig. 1.—*Top,* esophageal bougie used for cytology, consisting of rubber-tipped wire guide, flexible spiral, and olive dilators. *Bottom,* detail showing rubber tip, gauze square threaded on wire, and olive attached to spiral.

Method

The method used in our present study combines the effectiveness of the gauze swab in obtaining cellular material with the convenience of a bedside or office procedure. An esophageal bougie of original design is used to push a small piece of gauze through the length of the esophagus, even past a stenotic lesion. The instrument (fig. 1) consists of two parts: (1) a stainless steel piano-wire guide, 110 cm. long, with a flexible woven-rubber tip, 6 cm. long and 3 mm. in diameter, fixed at one end and (2) a steel spiral, 65 cm. long and 2 mm. in diameter, which slides over the piano-wire guide and has at one end a rounded collar 3 mm. in diameter and at the other end a thread onto which can be screwed olive dilators ranging in diameter from 6 to 12 mm. (19 to 37 F.). The procedure for obtaining cytological specimens is carried out with the patient sitting up and with no preparation other than overnight fasting. This is necessary so that the esophagus, if partially obstructed, does not contain food residue that would make the specimen unsatisfactory. First, the guide wire is introduced by leading its flexible rubber tip into the hypopharynx with the index finger. This guide is then gently advanced until its tip is in the stomach, at which point slight resistance is easily felt. If an obstructing lesion i encountered in the esophagus, the wire is ease lightly back and forth and at the same time rotate until its soft tip finds the lumen in the esophagu and slides past the lesion without forcing. With the guide in place, a piece of fine-mesh gauze approximately 1.5 cm. square is placed on the wire, followed by the spiral with a 6 mm. (19 F.) olive attached, and this is pushed down the full length o the esophagus, carrying the gauze before it, until i meets the tip of the wire in the stomach, and the the entire assembly is withdrawn as a unit. Th whole procedure takes less than a minute. The ti of the guide wire and the olive are then separate slightly (fig. 1, *bottom*), and from the gauze between them smears are made, carefully transferrin as much material as possible to slides and immediately fixing them by immersion in alcohol-ethe mixture. The procedure then is carried out a secon time.

It is important to note that if the passage of th olive dilator is hindered by a partially obstructin lesion, it is quite safe to exert a moderate amoun of pressure in an effort to force the gauze past th lesion, since the previously inserted guide wire obviates the danger of perforation. If the smalles olive cannot pass a stenotic area, then the repea procedure is carried out with the spiral reverse using the small rounded collar at its other end t push the gauze down the esophagus. On the othe hand, if no resistance is met the first time, then th second time a slightly larger gauze square and larger diameter olive are employed. The objectiv in any case is to have the gauze rub the involve esophageal mucosa, gently abrading from any lesion enough cells to give the cytologist unequivoca evidence.

In this study the slides were stained by a mod fied hematoxylin-eosin method devised by one o us (V. L.). The simplicity and rapidity of this staining procedure are advantageous for any cytologica study. After the smears have been in the alcoho ether fixative for a minimum of five minutes, the are removed, air-dried, and immersed in Harris hematoxylin for one minute. Then they are washe briefly in tap water, dipped two or three times in very dilute (approximately 1.0%) hydrochloric acid solution, and washed again in tap water. Next, the slides are placed for 10 to 12 seconds in dilute (0.5%) eosin solution, then dehydrated in two changes of 95% alcohol and two changes of absolute alcohol, cleared in xylene and mounted with Permount. The entire staining procedure can be accomplished easily in less than 10 minutes.

The cytological criteria in preparations stained by this technique are essentially similar to those with the Papanicolaou stain.[1] Size, shape, staining, and arrangement of the cells are important in determining whether they are benign, malignant, or atypical. Most significant of all is nuclear detail. Regardless of size, shape, or staining of cells, the presence of irregular nuclear borders, dense chromatin, and prominent nucleoli is more diagnostic of tumor cells than a combination of the previously mentioned factors. No single characteristic, such as unusual size or hyperchromaticity, is worthy evidence of a malignancy. The diagnosis should be based on the occurrence of several abnormal characteristics, found not just in one cell but in many cells.

An important difference between the method for obtaining cellular material described here and the lavage method is that we often obtain tiny bits of tissue, up to 1 mm. in size and grossly visible. Although it would be feasible to fix, imbed, and section these tissue fragments by standard histological practice, it has been more convenient to make "imprint" or "touch" preparations, as performed with comparable material in bone marrow aspirates. This is done by lightly touching the tissue fragment repeatedly between a pair of slides, thus leaving on each slide "prints" of a layer of cells. Such material presents masses of perfectly preserved cells that permit unequivocal differentiation of benign and malignant tissue (fig. 2).

Results of Esophageal Cytology

	Cases, No.	Cytological Interpretation		
		Negative (No Tumor Cells)	Doubtful	Positive (Tumor Cells Present)
Benign esophageal diseases	23	23	0	0
Carcinoma, epidermoid, of esophagus	13	0	0	13
Adenocarcinoma, involving esophagus, primary in stomach	8	3	2	3
Technical failure	5	...	...	...

Results

The results that we obtained by our technique in 44 cases are shown in the table. The group of benign diseases comprised nine cases of cardiospasm (achalasia), eight of esophagitis, four of stricture, and two cases of diffuse esophagospasm. The diagnosis was confirmed in 2 of these 23 cases at operation. In the others, the impression of benignity was supported by all other clinical evidence and by subsequent progressive improvement during a follow-up period of 6 months minimum and 14 months average for the whole group. The 21 cases of carcinoma were proved by biopsy, surgery, or autopsy. The squamous cell tumors were primary in the esophagus, while the group of adenocarcinomas were growths involving both the lower end of the esophagus and the cardia of the stomach, which presumably was the site of their origin. An additional group listed in the table, the technical failures, consisted of patients having such a high degree of obstruction that the 3-mm. (10 F.) rubber tip of the piano-wire guide could not be passed through the area of obstruction, and therefore the lesion could not be wiped with the gauze. The significance of this group will be discussed later.

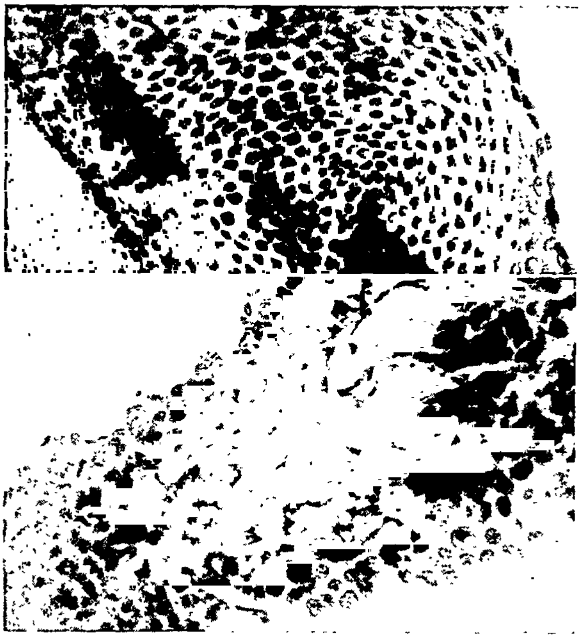

Fig. 2.—"Touch" preparations from tissue fragments obtained by gauze-sponge. *Top,* normal squamous epithelium. *Bottom,* epidermoid carcinoma.

These data indicate that a positive report of finding tumor cells by this technique was reliable, without exception in this series. There were no false-positive diagnoses in the benign cases. Neither were there any instances of failure to find malignant cells, leading to mistaken negative diagnoses, in the cases of primary epidermoid (squamous cell) carcinoma of the esophagus. It is informative also to analyze the results further according to the location of the lesion. Eleven of the benign lesions and 12 of the primary esophageal cancers were seen by x-ray to be situated above the esophagogastric junction. In the differential diagnosis of such lesions, which did not afford the possibility of being gastric in origin, the cytological method was consistently trustworthy in this series. On the other hand, the 21 patients with lesions demonstrated by roentgenographic examination to be located at the esophagogastric junction presented a problem, since a lesion of the lower end of the esophagus may be produced by extension of carcinoma of the cardiac end of the stomach. Eight such cases occurred in this series, with the gastric origin of the growth being suspected by x-ray in half of them. Esophagoscopy in six revealed no visible tumor, the esophagus apparently being involved extrinsically, with no mucosal lesion seen in the lumen. It is not surprising, therefore, that the diagnostic accuracy in these eight cases was as disappointing as with other cytological methods in carcinoma of the stomach.

Failure to accomplish properly this technique of cytological study, which occurred in five cases, gave a group in which the diagnosis by cytology was indeterminate. The significance of these technical failures must be assessed with reference to their recognition and their effect on the management of the patient. With the method described here, technical failure cannot occur without being recognized. One usually can tell when the tip of the guide wire has reached the stomach by sensing the slight resistance and observing how far the guide has been introduced, and one cannot fail to feel with certainty whether or not the olive-tipped dilator has pushed the gauze past a partially obstructing lesion. If it has not, one can anticipate that the cellular material will be inadequate. Thus, a technical failure will not be mistaken for a valid negative cytology. These failures, in our experience, are of no consequence in the management of the patient. Lesions producing such a degree of narrowing of the lumen that the tip of the guide cannot pass are lesions that, even if benign, are too far advanced to be treatable by bougienage. In such cases, nearly complete obstruction itself has proved to be an indication for resection, without regard for the differential diagnosis of the nature of the lesion.

Comment

In the 44 cases in which this technique was performed properly, interpretation of the smears was made not only with accuracy but also with ease. Cells were present in large numbers, often in sheets or clumps. There were no instances of doubtful interpretation due to inadequacy of the cellular material, the type of case that presents the most difficult problem to the cytologist. Theoretically, a diagnosis of malignancy may be based on identification of a single typical tumor cell. From the practical standpoint, few cytologists are willing to let such a grave decision rest on one cell. This is particularly true because in most cases of malignant neoplasm every exfoliated tumor cell does not exhibit all the diagnostic criteria of cancer. Diagnosis depends rather on synthesizing, from a number of cells observed, a composite picture that is characteristic of malignancy. The more cells present, the clearer this picture may be and the more reliable the interpretation. Accuracy of diagnosis depends also on obtaining cells in a well-preserved state. The method used here does this consistently, pr vided the material rubbed from the lesion by th gauze is smeared on slides as soon as the gauze i withdrawn from the esophagus and that the slid are at once immersed in fixative.

Another consideration bearing on the accuracy cytological methods that must be emphasized that they are in fact sampling processes subject t statistical laws. The probability of identifying tum cells in a case of cancer therefore depends on th total number of cells sampled. Any technique th puts more cells on the slide will inevitably gi greater diagnostic accuracy.

The evaluation of any new technique requires careful scrutiny of its possible hazards. We believe that the method presented here should not be used where esophageal varices are suspected because of the potential risk of inducing hemorrhage. Varices usually can be differentiated from carcinoma by roentgenographic examination. In the occasional case where this leaves some doubt, esophagoscopy is conclusively diagnostic. With this possible exception, the technique appears to carry no risk of hemorrhage. Although the gauze frequently was blood-stained after rubbing past a lesion, significant bleeding did not occur in any of our cases. The potential risk of perforation is eliminated by exercising gentleness and discretion in advancing the rubber-tipped guide wire. Once it is in place, it unfailingly leads the dilator through the lumen with no danger. An esophageal diverticulum, which none of the patients in this series presented, would require particular care in the introduction of the guide. We have used this guide wire and the olive-tipped bougies for therapeutic dilatation several hundred times in the past seven years without accident.

Summary and Conclusions

A new method for obtaining material from the esophagus for use in cytological examination is carried out by the pushing of a small piece of gauze past a suspected lesion by means of an esophageal dilator introduced over a rubber-tipped guide wire. Smears made from the material thus obtained contain large numbers of well-preserved cells, facilitating accurate differentiation of benign from malignant lesions.

With the use of this technique in 44 patients, correct negative diagnoses were made in all of 23 cases of benign esophageal disease, and correct positive diagnoses of malignancy were made in all of 13 cases of epidermoid (squamous cell) carcinoma. No errors were made in the differentiation of lesions located above the esophagogastric junction. Lesions situated at the esophagogastric junction may present difficulty, since this method frequently may give a negative result with a tumor at this site that is a gastric neoplasm rather than a primary esophageal carcinoma. The results suggest that this technique should give a higher percentage of correct cytological diagnoses than lavage methods and that it may permit more early detection of cancer of the esophagus.

HAZARDS OF ANTIBIOTIC THERAPY

Wallace E. Herrell, M.D., Lexington, Ky.

The indiscriminate use of antibiotics has created serious problems. Two episodes here given illustrate the misuse of penicillin. Patients for whom it is ordered should be questioned as to evidence of sensitivity, and after an injection they should be watched by a physician or nurse for 30 minutes. Reactions, if they occur, should be treated not with oxygen but with epinephrine or with steroids intravenously. The use of streptomycin is rarely followed by major complications, but its minor side-effects include contact dermatitis, and its toxic effects on the eighth cranial nerve, though not life-endangering, are distressing. Preliminary studies indicate that dihydrodesoxystreptomycin is less toxic. The fact that the tetracyclines are highly effective and can be given by mouth has resulted in widespread misuse. They can cause blood dyscrasia and anaphylactic reactions, but the most serious major hazard is superimposed staphylococcic enterocolitis and wound infections. There is a definite association between chloramphenicol and aplastic anemia. The rational use of antibiotics in the future depends on a return to strict aseptic technique in hospitals. The occasional temporary exclusion of one or more antibiotics from the hospital, long enough for the common pathogens to regain their sensitivity to it, would greatly improve the effectiveness and increase the safety of antibiotic medication.

Some may feel that the topic of the hazards of antibiotic therapy has been overlabored. It is my conviction, however, that a discussion of this subject is more important today than it has been at any time since the introduction of antibiotics almost 20 years ago. Sir Alexander Fleming's life was largely devoted to studying microbes and their behavior. In 1918, he became interested in wound infections, and it was in 1929, while he was studying the behavior of staphylococci, that the famous contamination of his culture occurred. Fleming, if he were here today, would be vitally interested in the problems that confront those of us who are occupied with the use of antibiotic agents in the treatment of infectious diseases.

The topic I am to discuss is the hazards of antibiotic therapy. Space does not permit detailed discussion of the nearly 20 antibiotics that are clinically available. I shall comment on the reactions of toxicity that may be encountered after the administration of the most commonly used antibiotics, classifying them as minor (non-life-endangering) or major (life-endangering and fatal) hazards.

Minor hazards of antibiotic therapy are drug rash (with or without pyrexia), angioneurotic edema and urticaria, serum sickness-like reaction, intestinal reactions (including diarrhea, nausea, and flatulence), superimposed infections (such as id reactions and infections due to Candida), certain neurotoxic reactions, and renal irritation. Major hazards of antibiotic therapy are anaphylactic reactions,

superimposed staphylococcic infections (including staphylococcic enterocolitis and staphylococcic septicemia), blood dyscrasia, and exfoliative dermatitis.

Penicillin

Penicillin possesses a low degree of toxicity. However, its widespread and indiscriminate use has created serious problems. The average yearly production of penicillin for human use at present is approximately 200 tons, which is equivalent to more than 2 billion average daily doses of 300,000 units each. It is not surprising, therefore, that problems have arisen.

The most commonly encountered minor reactions to penicillin include drug rash (with or without pyrexia); angioneurotic edema and urticaria; serum sickness-like reaction; and id reactions. These reactions are troublesome to be sure, but their management poses no great problem.

The major hazards of penicillin therapy today are anaphylactic reactions and superimposed staphylococcic infections. Welch and associates,[1] in a recent survey, reported a mortality of approximately 10% in 793 cases of anaphylaxis due to penicillin over a three-year period. This reaction occurs with about equal frequency in both sexes. I would like to emphasize, however, that it occurs less frequently in individuals less than 12 years of age. It is also evident that anaphylactic reactions to penicillin usually occur after the intramuscular administration of procaine penicillin G. The figure of 793 cases in a three-year period may well be conservative, since many reactions of this type are not reported. My own experience, however, agrees closely with the quoted mortality of approximately 10%. I believe that early recognition and immediate treatment of anaphylactic reactions to penicillin would lower the mortality. The following case report is a typical example of the hazard under discussion.

A 48-year-old, previously robust and healthy man was admitted to the hospital at 6 p.m., because of cough, fever, and chills of six days' duration. He had received symptomatic treatment for three days. There were physical signs of pneumonia in the left upper lung, and roentgenographic studies revealed pneumonia in that lobe. Laboratory study results were negative, except for a leukocyte count of 23,600 per cubic millimeter. There is no record that the patient was questioned concerning any previous sensitivity to penicillin. The resident ordered 1 million units of procaine penicillin G to be administered by the intramuscular route. This was done by the nurse, who then returned to her station. Twenty minutes later the patient was found dead. Postmorten examination revealed pneumonia in the left upper lobe and edema in the remaining lung tissue. No other significant cause for the patient's death was found.

This report of a case from a hospital is, I fear, an example of an anaphylactic cause of death that might have been prevented. The conspicuous deficiencies in the management of this case were that no attempt was made to elicit the history of previous sensitivity to penicillin and that the patient was left alone after injection of the antibiotic. Since experience has shown that anaphylactic reactions to penicillin occur within 30 minutes after its administration, a physician or a nurse should remain with the patient during that time.

The following report, with the headline "Penicillin Reaction Kills Woman," appeared in a leading newspaper in a metropolitan city in March, 1958:

> (Name of city).—(Name of woman), 34, 705 N. W. Second St., died Friday night in ——— Hospital as the result of a reaction to penicillin administered for contusions she suffered in a beating, Dr. ———, county medical examiner, said. A penicillin reaction severe enough to cause death is "rare," he added. Police Officer ———, called to the hospital when the woman was admitted for treatment, said the drug was given by a nurse. The nurse called Dr. ——— as soon as the reaction set in and the injured woman's breathing became difficult, according to ——— (the police officer). Dr. ——— placed the woman in an oxygen tent, but she died about 20 minutes later. (The police officer) ——— said the woman told him after the reaction set in that she had been similarly affected before. He said her injuries were not serious.

I believe that several principles of antibiotic therapy were violated in this case. The antibiotic was administered for contusions, in the absence of any demonstrable infection. The history of previous sensitivity to penicillin was not elicited before its administration. Treatment was carried out without a physician in attendance. When the reaction occurred, oxygen was administered, instead of epinephrine or steroids intravenously. Finally, the newspaper report states that this type of death is rare, which, unfortunately, is untrue.

Superimposed staphylococcic enterocolitis and septicemia, major hazards of antibiotic therapy, do occur occasionally after the administration of penicillin. From my own experience and that reported by others, I would estimate their incidence is probably no greater than 1%. I therefore propose to discuss these hazards later. Likewise, blood dyscrasia is quite uncommon after penicillin therapy. Fatal exfoliative dermatitis is a rare reaction but is a serious problem when it does occur. It is a major threat in an individual who is sensitive to penicillin and who receives long-acting penicillin, such as benzathine preparations. For this reason, I rarely use such preparations.

Streptomycin and Dihydrodesoxystreptomycin

Streptomycin.—Several minor hazards may be encountered after the administration of streptomycin. Drug rash, although not common, sometimes occurs. Perhaps the most troublesome cutaneous toxic reaction to streptomycin is contact dermatitis. The most serious minor hazard of streptomycin therapy is toxicity for the eighth nerve. It is well known that disturbance of the vestibular branch of the eighth nerve occurs more often when the streptomycin base is used, while impairment of the auditory branch of the nerve is a more common occurrence after the administration of dihydrostreptomycin. Circumoral paresthesia is a not uncommon reaction to either form of streptomycin. It should be emphasized that, although neurotoxic reactions may be distressing to the individual who experiences them, they are, for the purpose of this discussion, classified as minor (non-life-endangering) hazards.

Major hazards, such as anaphylactic reactions, superimposed staphylococcic infections, and blood dyscrasia, rarely have occurred after the administration of streptomycin.

Dihydrodesoxystreptomycin.—Dihydrodesoxystreptomycin sulfate is a chemical analog of streptomycin developed by Ikeda and associates[2] at the Scientific Research Institute in Tokyo. Their studies suggested that this preparation was as active as, or slightly more active than, the parent compound and was less toxic. For the past six months my colleagues and I have carried out some clinical studies on this antibiotic. To date we have used it in the treatment of 51 patients. Twenty-six of these patients were suffering with a variety of severe, acute infections. The average daily dose of dihydrodesoxystreptomycin was 1 to 2 Gm., given in divided doses every 12 hours by the intramuscular route. We have administered as much as 2 Gm. of the antibiotic daily for 14 days. If continued longer, the dosage was reduced to 1 Gm. daily. We have successfully administered dihydrodesoxystreptomycin by the intrathecal route, also. The recommended dose is 100 mg. per injection. Twenty-five patients with culturally proved pulmonary tuberculosis also have been treated with dihydrodesoxystreptomycin. This study was carried out in collaboration with Dr. James T. Gilboy at the Julius Marks Sanatorium in Lexington, Ky. In the treatment of tuberculosis, the antibiotic was administered in doses of 1 Gm. twice weekly. Our studies to date, although preliminary, permit us to make the following statement: When compared with other forms of streptomycin, dihydrodesoxystreptomycin causes less pain at the site of injection, a lower incidence of paresthesias of the face and mouth, and less neurotoxic reactions. For example, transient impairment of hearing has been reported in only one case and dizziness or evidence of vestibular disturbance in none. These studies will be reported in detail elsewhere. If further experience confirms that to date, use of streptomycin in this form may greatly reduce the minor hazards encountered after administration of this antibiotic.

Tetracyclines

The tetracyclines are highly useful antibiotics. It is my conviction, however, that their use is attended by some of the major hazards of antibiotic therapy. The fact that these antibiotics can be administered effectively by the oral route has resulted in their widespread and indiscriminate use. Minor hazards that may follow administration of the tetracyclines include drug rash (which is not common), urticaria, and mild gastrointestinal disturbances. Superimposed infections due to Candida, which are of a local character, constitute another frequently encountered problem.

Major hazards, such as blood dyscrasia, exfoliative dermatitis, and anaphylactic reactions, rarely occur after the administration of the tetracycline antibiotics. Superimposed staphylococcic infection is, in my opinion, the most serious major hazard of antibiotic therapy in hospitals today. There is strong evidence to support the statement that the widespread and indiscriminate use of the tetracyclines is the chief factor involved. The two most serious superimposed staphylococcic infections are staphylococcic enterocolitis and severe wound infections with sepsis.

Staphylococcic Enterocolitis.—Staphylococcic enterocolitis is an important problem. I would like to draw attention again to the mortality of one of the major hazards of antibiotic therapy, namely, anaphylactic reactions to penicillin, which is approximately 10%. Available published material and my own experience lead me to conclude that the mortality of staphylococcic enterocolitis is in the order of 40%. This high rate undoubtedly is due to two factors: lack of recognition of the disease and inadequate treatment. The following case is an example.

The patient, a 37-year-old woman, previously had been in excellent health. Thirty-six hours before her admission to the hospital she experienced epigastric pain, which later shifted to the right lower quadrant of the abdomen. A diagnosis of acute appendicitis was made, and appendectomy was performed. The appendix was found to be acutely inflamed and gangrenous. There was a slight amount of peritoneal soiling. The patient received 400,000 units of penicillin and 0.5 Gm. of streptomycin postoperatively and again 12 hours later. On the second postoperative day, because of slight fever (101 F [38.3 C]), oral administration of tetracycline (Achromycin) was begun in a dosage of 250 mg. four times daily. On the third postoperative day her temperature was 103 F (39.4 C) and pulse rate 110 beats per minute. The tetracycline therapy was continued. There was considerable abdominal distention, and peritonitis was suspected. On the fourth postoperative day the possibility of staphylococcic infection was first considered, and swabs from the rectal secretions were made. Gram's stains revealed many clusters of a gram-positive cocci, which later, on culture, was identified as coagulase-positive Staphylococcus (Micrococcus) pyogenes var. aureus. On the fifth postoperative day tetracycline therapy was discontinued and the surgical resident ordered erythromycin administered by the intravenous route. Shortly thereafter, the patient, whose temperature had risen to 105 F (40.5 C), died. Autopsy revealed extensive staphylococcic enteritis, limited to the small intestine.

The significant points illustrated by this case are as follows: 1. It is doubtful that prophylactic use of the antibiotic was indicated. 2. The clinical picture of distention and shock was interpreted as possible peritonitis rather than ileitis. 3. Diarrhea was absent, as is often the case when the disease is limited to the ileum. 4. The patient's clinical course prompted the clinician to continue the administration of the broad-spectrum antibiotic by the oral route. 5. When, late in the course of the illness, erythromycin therapy was begun, the antibiotic was administered by the intravenous route, although it would have been far more effective had it been given through the nasal catheter and every effort made to get it directly into the intestinal tract.

Severely Infected Wounds with Sepsis.—I believe that the widespread, indiscriminate use of broad-spectrum antibiotics eliminates sensitive strains of micrococci from patients soon after their admission to hospital wards, leaving them vulnerable to attack by the resistant micro-organisms they encounter if they remain more than a few days in the hospital. This accounts for the marked increase in the wound infection rate, which results in increased morbidity and, often, serious complications, including staphylococcic septicemia.

Chloramphenicol

The minor hazards of antibiotic therapy are relatively insignificant in connection with chloramphenicol. Likewise, some of the major hazards—namely, anaphylactic reactions, exfoliative dermatitis, and superimposed staphylococcic infections—rarely occur after the administration of chloramphenicol. There can be no mistake, however, concerning the possibility of serious and fatal blood dyscrasia after the use of this antibiotic, alone or in combination with other antibiotics. The blood dyscrasia may take the form of aplastic anemia, agranulocytopenia, or thrombocytopenic purpura. By far the most common is aplastic anemia, which, unfortunately, is almost always fatal. The chance of successful treatment of blood dyscrasia is far less than that of anaphylactic reaction (10% mortality) and superimposed staphylococcic enterocolitis (40% mortality). Individuals in the younger age groups are particularly susceptible to blood dyscrasia after the administration of chloramphenicol, in contrast to the low incidence of anaphylactic reactions to penicillin in that age group. Almost 50% of cases of aplastic anemia to date have occurred in the younger age group, predominantly in white females. The following report of a case is a fairly typical example of the major hazard under discussion.

The patient, a 7-year-old girl, was admitted to the medical service of a hospital on Dec. 6, 1957. She had had measles and chicken pox. For two years she had had frequent respiratory infections and mild asthma. On Nov. 1, 1957, she had been hospitalized because of bronchopneumonia and treated with a suspension of chloramphenicol for 11 days with good response. On Dec. 2, characteristic lesions of purpura were noted on the child's ankles and she was found to be very anemic. She received 500 cc. of blood. On admission to the hematology service, her erythrocyte count was 3,500,000 per cubic millimeter, hemoglobin concentration 11.1 Gm. per 100 cc., platelet count 25,000, and leukocyte count 2,100 per cubic millimeter. The differential count was as follows: neutrophils 8%, lymphocytes 89%, monocytes 1%, and eosinophils 2%. Bone marrow aspiration revealed only a few normal elements; most of the cells identified were plasma cells and mature lymphocytes. Findings in the remainder of the laboratory and roentgenographic studies were negative. The patient was dismissed three days later. On Dec. 25, she was readmitted because of epistaxis and a perirectal infection. Her temperature became extremely high and spiking, and there was bleeding from her gums. Blood cultures were positive for Escherichia coli. The patient died on Jan. 2, 1958. Autopsy findings confirmed the clinical diagnosis of aplastic anemia.

I have pointed out repeatedly in the past the definite association between the administration of chloramphenicol and the development of aplastic anemia. It seems to me the problem is clear-cut. Chloramphenicol is the drug of choice in the treatment of typhoid and salmonellosis. It is also effective against some infections due to strains of Staph. pyogenes var. aureus that are resistant to other antibiotics. Therein lies its usefulness. There seems little justification for using chloramphenicol in preference to other available agents in the treatment of pneumococcic and streptococcic infections, particularly in the younger age group.

Erythromycin

Erythromycin is an antibiotic that has been widely used. Minor hazards that have been encountered after its administration are drug rash (rare) and, on occasion, flatulence and diarrhea (which usually occur when the dosage of erythromycin exceeds 300 mg. every six hours). Erythromycin is by far the least toxic of the commonly used antibiotics. I am unaware of any major or life-endangering hazard that has resulted from its use.

Miscellaneous Antibiotics

Neomycin.—Toxic effects on the eighth cranial nerve and renal irritation are the two most troublesome reactions that may occur after the administration of neomycin.

Bacitracin.—Impairment of renal function may result when bacitracin is administered in doses in excess of 10,000 units four times daily.

Polymyxin.—Severe pain at the site of injection and neurotoxic effects, such as paresthesias and cerebellar ataxia, are common reactions to polymyxin.

Novobiocin.—There is a high incidence of cutaneous toxic reactions, with or without fever, after administration of novobiocin. In my experience, the incidence of this reaction is in the order of 20%.

Vancomycin.—Vancomycin, a new antibiotic, is active against strains of Staph. pyogenes var. aureus that are resistant to many other antibiotics. Impairment of function of the eighth nerve after its administration has been reported. This toxic effect is greatly increased if vancomycin is administered in the presence of impaired renal function. Hyperpyrexia, drug rash, and severe phlebitis at the site of injection also have been reported to follow vancomycin therapy.

Amphotericin B.—This antibiotic shows promise in the treatment of certain systemic mycoses. In my experience with it, which is limited, there appears to be a wide variation in different persons' ability to tolerate this drug. Chills and hyperpyrexia are the most troublesome reactions when the dose of amphotericin B is in excess of the patient's tolerance. Transient azotemia also has been observed after administration of this antibiotic.

Ristocetin.—Definite but transient leukopenia has been reported after ristocetin therapy.

Comment

It is my opinion that the three major hazards of antibiotic therapy are anaphylactic reactions, superimposed staphylococcic infections, and blood dyscrasia. Although many of the antibiotics have been incriminated in all of these hazards, the evidence suggests that serious and often fatal anaphylactic reactions are most common after the administration of procaine penicillin G by the intramuscular route; serious and often fatal superimposed staphylococcic infections, largely a problem in hospitalized patients, are due at least in part to the widespread use of the broad-spectrum antibiotics; and serious and often fatal blood dyscrasia occurs most frequently after the administration of chloramphenicol. A discussion of the hazards of antibiotic therapy would fail in its purpose if recommendations were not made for curtailing and controlling them. Therefore, the following recommendations are made.

Anaphylactic Reaction.—Discourage and discontinue the indiscriminate use of penicillin. Never administer procaine penicillin G by the intramuscular route to patients with a history of previous sensitivity to this antibiotic or repeated allergic manifestations, including asthma. Keep any patient to whom procaine penicillin G is administered intramuscularly under observation for at least 30 minutes after the injection. When an anaphylactic reaction occurs, immediately administer epinephrine hypodermically or steroids intravenously or, in some instances, both.

Superimposed Staphylococcic Infections.—Abolish the routine prophylactic use of all antibiotics in patients with uninfected surgical wounds of all types. Insist on a return to strict aseptic technique in the surgical suites and in the dressing of all wounds. Immediately obtain a culture of all wounds suspected of being infected and study the microorganisms, especially Staph. pyogenes var. aureus, by means of sensitivity tests and bacteriophage typing. Isolate every patient in the hospital with a staphylococcic infection. If necessary, reopen the isolation wards formerly inhabited by patients suffering with common contagious diseases. Make cultures periodically of the nasopharynx of personnel in hospitals, particularly those in so-called key areas. Treat or remove these individuals when they are found to harbor antibiotic-resistant microorganisms. Do not hesitate to manipulate the antibiotics. For example, exclude from use in the hospital one or more of the antibiotics for a long period of time and then readmit them if the common pathogens regain their sensitivity. Return to a well-documented method of preventing surgical complications in certain abdominal procedures, namely, the installation of 5 Gm. of sulfathiazole in the peritoneum at the time of abdominal surgery when there is evidence of soiling of the peritoneum.

Blood Dyscrasia.—We must accept the available evidence that strongly suggests the connection between the use of chloramphenicol and the development of blood dyscrasia. Restrict use of this antibiotic to the treatment of typhoid, salmonellosis, and the occasional infection caused by Staph. pyogenes var. aureus that is resistant to other available antibiotics. Condemn the use of chloramphenicol in the treatment of mild, non-life-endangering infections of all kinds. Do not administer this antibiotic to patients in the younger age group (under 12 years of age), with the possible exception of those suffering with typhoid or salmonellosis.

DIETARY APPROACH TO ATHEROSCLEROSIS.—Atherosclerosis is the Number One public health problem. Many factors have been implicated in the pathogenesis of this disease. Prominent among these factors is the amount and kind of fat in the diet. The evidence now appears to be conclusive that sufficient quantities of polyunsaturated fat in the diet, with proportional decrease in saturated fat, will result in major decrease in blood lipid. Some evidence indicates that such blood lipid lowering produces a desirable effect upon existing atherosclerosis. Much additional time and work will be required to clarify the prophylactic and therapeutic value of this type of dietary approach.—Harry Balch, M.D., Stanford Splitter, M.D., Paul Flynn, M.D., and L. W. Kinsell, M.D., The Relationship of Dietary Fat to Atherosclerotic Disease, *California Medicine,* September, 1958.

TREATMENT OF POLYCYTHEMIA VERA WITH BUSULFAN (MYLERAN)

John Louis, M.D., Chicago

Polycythemia vera was treated in 18 patients in whom the disease had existed for periods ranging from two months to 10 years. Most of the patients had been treated previously by various means, and three were in a state of partial remission (having normal hematocrit readings) at the time of the study. All were treated with busulfan (Myleran) by mouth. Initial dosages ranged from 2 to 10 mg. daily; maintenance dosages ranged from 8 mg. per day to 2 mg. per week. In seven patients this treatment was supplemented with venesection. Complete remission (normal hemograms with absence of signs and symptoms of polycythemia vera) was obtained in 11 patients; incomplete remission (normal hemograms with persistence of one or more signs or symptoms of the disease) was obtained in 6; partial remission occurred in one case. Hematocrit values, which ran as high as 70 in some male patients, returned in every case to normal levels (less than 54% for men). Leukocyte counts were lowered in every case and fell to leukopenic levels (less than 3,500 cells per cubic millimeter) in three. Two patients, whose case histories are given, developed anemia and thrombocytopenia in addition to leukopenia. Close supervision of the patients receiving busulfan therapy is necessary if excessive depression of the bone marrow is to be avoided. The ultimate place of this drug in the treatment of polycythemia vera remains to be determined.

Busulfan (Myleran) has been an effective agent for the treatment of chronic granulocytic leukemia; however, it has been reported to be of little therapeutic value in other myeloproliferative diseases. Currently there are three methods for the treatment of polycythemia vera; they include the use of venesection, radioactive phosphorus (P^{32}), and triethylene melamine. Each method has a disadvantage. Venesection, though it decreases the red blood cell mass, has little effect on the leukocytes and thrombocytes, so that many of the complications associated with increase in these elements continue to be manifested. Repeated venesection, in addition, leads to an unphysiological state of iron deficiency. Therapy with radioactive phosphorus produces a more nearly normal state, since all of the marrow elements are suppressed. However, certain hematologists are of the opinion that this form of therapy is associated with a greater incidence of leukemia. Though this objection has not been conclusively documented, the possibility of such side-effects has tempered enthusiasm for the use of this agent in the treatment of polycythemia vera.

These objections to current methods of therapy made it desirable to investigate the relative merits of other marrow-suppressing agents. During the past eight years we have evaluated such agents. At the suggestion of Dr. J. H. Burchenal we studied the effect of busulfan in the control of the polycythemic state.[1] The present report deals with one and one-half years experience in the treatment of polycythemia vera with busulfan.

Methods and Results

Eighteen patients with polycythemia vera were treated with busulfan for 4 to 76 weeks (mean 38 weeks). There were 8 women and 10 men, with ages ranging from 50 to 71 years (mean 62.8 years). The diagnosis of polycythemia vera was established by the usual hematological techniques. The known duration of illness ranged from two months to 10 years. All except three patients had received prior therapy. Seven patients had been previously treated with combinations of radioactive phosphorus, triethylene melamine, and venesection. Eight patients had received intermittent courses of therapy with triethylene melamine and venesection.

Hematocrit readings at the onset of therapy ranged from 47 to 70% in the men and from 50 to 55% in the women. Three of the men were not polycythemic at the onset of therapy and were, therefore, given maintenance doses of busulfan. The initial dose of busulfan varied from 2 to 10 mg. per day for intervals of 1 to 12 weeks. The mean dose per day of the initial treatment period ranged from 2 to 4 mg. per day (mean 3.0 mg.; median 3.0 mg.; 95% limits 1.5 to 6.5 mg.). The median of the initial treatment period, from the beginning of therapy with busulfan to the onset of remission, ranged from 1 to 57 weeks (mean 19 weeks; median 10.2 weeks; 95% limits 1 to 80.6 weeks). This therapy lowered hematocrit values to normal (males < 54%, females < 48%) in all of the patients treated and represented reductions of 2 to 19% (mean 7.2%). In seven of the patients venesection was done in conjunction with busulfan therapy: two, 500 ml.; one, 1,000 ml.; three, 1,500 ml.; and one,

5,000 ml. An obvious correlation between the dosage of busulfan and the degree of hematocrit reduction was not apparent.

Leukocyte counts were lowered in each instance. Nine patients had leukocyte counts greater than 12,500 cells per cubic millimeter (range 16,000 to 54,000). In these patients the leukocyte count became normal in all except two, after 1 to 50 weeks of therapy (mean 16.3 weeks). Two patients whose counts were still elevated at the time of this analysis had counts of 13,000 and 19,000 cells per cubic millimeter after 3 to 21 weeks of therapy. Reduction in the leukocyte count either preceded, concurred with, or, most frequently, followed the decrease in the hematocrit readings. The changes in the leukocyte count, therefore, did not necessarily parallel reductions in the hematocrit readings.

For the purpose of analysis in this report, a complete remission refers to attainment of a state with a normal hemogram and the absence of signs and symptoms referable to polycythemia vera. An incomplete remission is attainment of a state with a normal hemogram but with persistent abnormalities in the signs and/or symptoms. Partial remission is attainment of a state with normal hematocrit reading but with abnormalities in the other formed elements in the blood. No response is failure of any change to occur.

The hematocrit readings were normalized in all of the patients treated. Eleven patients attained complete remission, six incomplete remission, and one a partial remission. Two patients reverted to their polycythemic state after complete remissions of 22 and 48 weeks. Both have responded to second courses of therapy. The remaining patients are in their initial remission, ranging from 4 to 58.7 weeks (median 17 weeks). All but two patients received maintenance therapy. The maintenance dose ranged from 2 to 18 mg. per week (mean 9.5 mg.) for intervals of 4 to 58.7 weeks (mean 24.6 weeks). The size of the maintenance dose was governed by changes in the peripheral hemogram. During the initial period of therapy patients were observed at weekly intervals until a remission was obtained. Subsequent to correction of the polycythemic state and stabilization of the hemogram, patients were observed at monthly intervals.

Spleens were palpably enlarged before the administration of busulfan in six patients. During remission the spleen could not be palpated in one; the size was decreased in four, unchanged in one, and enlarged in another patient whose spleen was not palpable prior to therapy. The liver was palpably enlarged in four patients prior to therapy with busulfan. During remission the liver appeared larger in two, was no longer palpable in the other, and was not altered in size in the fourth patient. Leukopenia (leukocyte counts $<$ 3,500 cells per cubic millimeter) occurred in three patients. In one the leukocyte count decreased to 3,100 cells per cubic millimeter but subsequently became normal after therapy was discontinued for one month.

Report of Cases

Two patients developed anemia and thrombocytopenia in addition to leukopenia.

Case 1.—A 55-year-old male had had polycythemia vera for three years prior to receiving busulfan. He had been previously treated with triethylene melamine and venesection. His last dose of triethylene melamine had been given four months prior to busulfan therapy. Maintenance therapy was instituted consisting of 2 mg. per day of busulfan for seven weeks. With the patient on this dosage the hematocrit reading rose from 48 to 56 mm. The dosage was then increased to 4 mg. per day for 16 weeks, with resulting decrease in the hematocrit reading to 54% and the leukocyte count to 6,600 cells per cubic millimeter. The dosage of busulfan was then reduced to 2 mg. per day for six weeks. Therapy was then discontinued because of a reduction in the leukocyte count to 2,800 cells per cubic millimeter. Subsequently the pancytopenia developed and progressed until five weeks after cessation of therapy when the leukocyte count was 1,900 cells per cubic millimeter, hematocrit reading 21%, and platelet count 19,520 cells per cubic millimeter. This state has persisted until the present time (20 weeks after cessation of therapy). The bone marrow contained normal cellularity of all the hematopoietic elements. Clinically, except for moderate weakness, the patient is asymptomatic and able to continue with his occupation.

Case 2.—Pancytopenia developed in a second patient receiving busulfan—a 55-year-old woman with polycythemia of four years' duration. Initially she received 4 mg. per day for two weeks. Her dosage was increased to 8 mg. per day for four weeks since the hematocrit reading increased from 52 to 54%. This reduced the hematocrit reading to 53%, but therapy was discontinued because of a drop in the leukocyte count from 15,300 to 4,500 cells per cubic millimeter. The ensuing pancytopenia progressed to its maximum intensity 13 weeks after therapy was stopped. At this time the hematocrit reading was 25%, leukocyte count 1,400 cells per cubic millimeter, and platelet count 30,000 cells per cubic millimeter. The patient was given a transfusion of 500 ml. of blood because of the onset of weakness, palpitation, and anginal pain. Bone marrow was adequate in cellularity for all the hematopoietic elements. The polycythemic state subsequently reappeared 48.5 weeks after cessation of therapy.

Comment

In this series of patients busulfan effectively alleviated the polycythemic state. The wide variation in dosage, however, necessitates frequent patient visits and makes the use of this agent more cumbersome than other forms of therapy. In 2 of 18 patients the development of unheralded pancytopenia further emphasizes the importance of close supervision of patients receiving this therapy. This problem further adds to the difficulty of establishing safe maintenance dosage. Venesection concomitant with busulfan therapy appeared to minimize this problem in the seven patients so treated. The delay in the manifestation of the marrow-suppressing effects from drug therapy appeared reduced by this procedure since smaller doses of busulfan were required. By this method, therapy is aimed at preventing elevation of the hematocrit reading to polycythemic levels rather than at effecting a reduction. Other side-effects from busulfan therapy have not been observed in this series to date.

Therapy with busulfan did not consistently reduce the size of the liver and spleen in polycythemia vera as in chronic granulocyte leukemia.[2] Further evaluation of this agent in the treatment of polycythemia vera will be required before its ultimate place in the therapy of this disease can be established.

Summary

Eighteen patients with polycythemia vera were treated with busulfan (Myleran). In seven of these venesection was used concomitantly. The hematocrit readings were reduced to normal in all of the 15 patients with elevated readings. Three patients maintained normal readings after receiving maintenance therapy. Initial dosage of busulfan was variable, ranging from 2 to 10 mg. per day for 1 to 12 weeks. Remissions lasted up to 65 weeks. All but two patients received maintenance therapy ranging from 8 mg. per day to 2 mg. per week. Transient leukopenia occurred in one and pancytopenia in two others. Close supervision of polycythemic patients receiving busulfan therapy is necessary to prevent excessive marrow suppression.

CLINICAL NOTES

ALCOHOL-INDUCED PAIN IN HODGKIN'S DISEASE

William E. Braun, A.B.
and
Bruce I. Shnider, M.D., Washington, D. C.

Ethyl alcohol, when ingested by patients with certain systemic diseases, may give rise to severe pain in the organ or organs involved by the disease process. At first, alcohol-induced pain was reported only in patients with Hodgkin's disease, and as a result was considered to be specific for this condition.[1] The most definitive statement supporting this phenomenon appeared in the Annotations of the *British Medical Journal*[11] and is quoted as follows: "Enough evidence has now accumulated to show that alcohol-induced pain in Hodgkin's disease is not just another of those clinical curiosities of little importance in the practical management of patients. So far this symptom has been reported only in Hodgkin's disease; it does not seem to occur in other types of malignant lymphomata or other neoplastic conditions."

Recently, reports of similar pain in condition other than Hodgkin's disease have become mor prominent in the medical literature[2] and have cas doubt on the specificity of this phenomenon. I 1953 Alexander[2a] reported the presence of alcoho induced pain in two instances of bone disease. H personally experienced this type of pain in Brodie's abscess of his tibia and also alluded to Lieutenant Colonel Graham who "suffered fro a pyogenic infection of bone and had experienced a similar alcohol-induced pain." Joske[2d] in discussing etiological factors in pancreatitis reported two cases in whom ingestion of only small amounts of alcohol resulted in severe pancreatic pain.

Not until 1957 did more extensive reports of the nonspecificity of this type of pain appear. James and co-workers[2b] reported two patients with carcinoma who had alcohol-induced pain at the site of their lesion and who as a result were given misdiagnoses of Hodgkin's disease. The first of these two patients noticed spontaneous relief from alcohol-

induced pain despite the fact that by x-ray her mediastinal mass had enlarged. The mediastinal mass was resected, and histological sections revealed a thymic carcinoma. The second patient at autopsy showed adenocarcinoma and necrosis of the pancreas, a similar growth in the lung, and a small adenocarcinoma in one kidney. Allowing for the possibility that in the first case the thymic carcinoma was a localized precursor of Hodgkin's disease and that in the second case the pancreatic lesion represented acute pancreatitis triggered immediately by alcohol ingestion, James and co-workers conclude: "With these reservations, our experiences suggest that alcohol-induced pain is not specific to Hodgkin's disease, but that it may occur in other malignant conditions, and that it may be the first indication of their presence. Had we known this, case one (thymic carcinoma) might have been explored while the tumour was still removable."

Another study by Conn and co-workers [2c] reported alcohol-induced pain in 4 of 98 patients tested. Two of these four had Hodgkin's disease, one a fractured hip, and one acute lymphangitis and sarcoidosis. In addition, histories of alcohol-induced pain were obtained in one case of giant follicular lymphoma, one case of Hodgkin's disease, and one case of an apparently normal male physician who was thoroughly checked for any evidence of Hodgkin's disease.

When alcohol-induced pain is present, symptoms may appear immediately after the ingestion of alcohol or after a latent period of 10 to 20 minutes. It usually continues for 15 minutes to three hours. Occasionally it may last a few seconds or a few days. Very small amounts of an alcoholic beverage, even a swallow of beer or a sip of sherry, can cause this pain, which may on occasion require morphine for relief. Characteristically, it is located at the site of the lesion, primarily bony or lymphatic, and at times more than one site may be involved.

In our series of 48 cases (see table), four patients with diseases other than Hodgkin's disease experienced alcohol-induced pain indistinguishable from that experienced by two of the patients with Hodgkin's disease.

Materials and Methods

A total of 48 patients were tested for alcohol-induced pain. Of these 48 patients 9 had Hodgkin's disease, one a lymphosarcoma, 15 bone and joint lesions, 12 had a miscellaneous group of malignancies with generalized metastases, and 11 had other diseases with associated lymphadenopathy (see table).

The ethyl alcohol was administered as an oral preparation in the form of vodka. The vodka used was 100-proof and calculated to be the equivalent of a 50% ethyl alcohol solution. Each patient was given 30 cc. of vodka mixed with an equal amount of orange juice. The clinical status and symptomatology of the patient to be tested were recorded. After the oral administration of the alcohol solution, any change in the patient's condition or symptomatology was noted. When pain did occur, personal observation was continued until the pain ceased. If no change occurred within 30 minutes, resident physicians continued observing the patient.

In all instances the preparation was given to the patients without their being aware that they were receiving alcohol, and when positive results were obtained these were checked by the administration of the orange juice alone.

TABLE 1.—*Diseases Evaluated for Alcohol-Induced Pain*

Diseases	Patients Tested, No.	Positive Results, No.
Lymphomas		
Hodgkin's	9	2
Lymphosarcoma	1	0
Bone and joint lesions		
Multiple myeloma	4	0
Osteomyelitis	4	1
Traumatic fractures	5	2
Osteoarthritis	2	0
Malignancies with metastases		
Carcinoma of the breast	2	1
Carcinoma of the lung	2	0
Carcinoma of the tonsil	2	0
Carcinoma of the esophagus	1	0
Melanoma	5	0
Other diseases with lymphadenopathy		
Pulmonary tuberculosis	6	0
Sarcoidosis	4	0
Nonspecific	1	0
Total no. of cases tested		48
Total no. of positive results		6
No. of positive results in Hodgkin's disease		2
No. of positive results in other diseases		4

Results

In the nine cases of Hodgkin's disease, two positive responses were obtained. The first patient was a 29-year-old female who had extensive involvement of her mediastinal, cervical, axillary, and inguinal lymph nodes. She had noted for several years that the ingestion of a cocktail or any other alcoholic beverage would produce pain in the supraclavicular area. At the time of admission she was found to have, in addition to the lymphadenopathy described, involvement of the supraclavicular nodes and a bony defect in the upper portion of the sternum. The ingestion of alcohol would produce a severe sharp pain in the region of the bony defect and in the supraclavicular lymph nodes after a latent period of about 10 minutes. This would last for approximately 5 to 10 minutes. It could be reproduced repeatedly by the administration of alcohol. There was no radiation and it remained localized to these areas without being manifest in the cervical, axillary, or mediastinal regions.

The second case was that of a 29-year-old male who had extensive involvement with Hodgkin's disease. Ten minutes after the ingestion of alcohol, this man became aware of the gradual onset of a dull aching pain over the cervical and axillary lymph nodes. This gradually increased in intensity, lasted for a period of 15 minutes, and then gradually disappeared. Again this symptom could be reproduced by the administration of alcohol at repeated intervals.

The next two cases demonstrated a similar type of pain produced in two patients who had traumatic fractures and were admitted to the orthopedic service. The first of these was a 46-year-old female who had a traumatic fracture of the right humerus. This patient noted the gradual onset of a dull throbbing pain at the site of fracture approximately 20 minutes after the ingestion of alcohol. This would gradually increase in severity over the next 20 minutes and then diminish and disappear. The usual duration of this symptom was about 30 minutes. The second case was that of a 29-year-old male who would develop a sudden severe pain at the site of his fracture 10 minutes after the ingestion of alcohol. This was excruciating in nature, would last for 5 or 10 minutes at this intensity, and would then gradually diminish. The duration of symptoms in this instance was 20 minutes.

Another case was that of a 43-year-old female with staphylococcic osteomyelitis involving the left hip, right tibia, and fibula. She demonstrated the sudden development of a severe sharp pain in the involved areas which would last 10 to 15 minutes and abruptly disappear.

The last case was that of a 44-year-old female who had extensive metastases from a carcinoma of the breast. This patient would note a stinging or at times a burning sensation in an axillary node which was invaded by an inflammatory metastatic process. This sensation would develop about one minute after the ingestion of alcohol and was of extremely short duration. However, it would be reproduced by repeated administration of the preparation used in this study. The administration of orange juice alone failed to reproduce this symptom.

Comment

Several theories have been proposed to explain the phenomenon of alcohol-induced pain. Hoster [1a] suggests that edema of the site involved may be responsible for the pain. However, de Winter [1e] reports a patient with an osseous lesion of Hodgkin's disease in the sacrococcygeal region who had relief of pain with hot baths. Since heat increases blood flow and causes vasodilatation, it might be expected on the basis of this theory to cause pain rather than to relieve it. Bichel and Bastrup-Madsen [1d] tested seven vasodilators in patients with Hodgkin's disease and alcohol-induced pain. None of these vasodilators (including glyceryl trinitrate ointment, histamine, and nicotinic acid) could reproduce thi symptom. Release of histamine at the site of th lesion has been suggested as a possible mechanism by Burchell,[3] however, histamine failed to produce pain in the studies by Bichel and Bastrup-Madsen Gros [1f] was able to alleviate the pain with antihistamines. This tends to support Justin's [11] theory tha vasomotor changes of an allergic nature are responsible. Dawe [4] points out that in many cases of th granulomatous type of Hodgkin's disease the lesion show deposits of hyaline fibrous material aroun smaller arteries and nerves. Swelling, induced b alcohol, in this material or in the nerve itself ma produce pain. It may be possible that alcohol ca induce swelling which heat alone cannot. Conn and co-workers [2c] propose that the irritating effect of the alcohol itself may cause the pain. It is obvious that the mechanism is not clear.

Clinical studies have demonstrated that this phe*nomenon is not specific for Hodgkin's* disease. Patients with other malignancies or bone diseases may experience pain which is indistinguishable from that seen in Hodgkin's disease after the ingestion or infusion of alcohol.

At times this finding of alcohol-induced pain may be of clinical value. Reliable clinical reports have confirmed its presence in patients with Hodgkin's disease, traumatic fracture, osteomyelitis, carcinoma of the breast, thymus, and pancreas, acute pancreatitis, acute lymphangitis, and sarcoidosis and by history (without confirmatory testing) in a case of giant follicular lymphoma and in a patient with no demonstrable pathology.[2c] The basic examination of such a patient should be directed to evaluate the presence or absence of these particular diseases.

Hoster,[1a] de Winter,[1e] and Godden and co-workers [1h] have suggested that in patients with alcohol-induced pain as a result of Hodgkin's disease the relief of this symptom might be used as an indication of successful palliative therapy. In addition, the appearance of pain at a new site in such an individual after the ingestion of alcohol may indicate new areas of involvement not yet clinically evident, and the physician should be alerted to this possibility.

In spite of these clinical implications, alcohol-induced pain must be considered a nonspecific phenomenon occurring in a variety of diseases, many of which may not yet be reported.

Summary

Forty-eight cases of various types of lymphadenopathy, bony lesions, and malignancy have been studied for the presence of alcohol-induced pain. After the oral ingestion of alcohol, in two cases of Hodgkin's disease, three cases of bone disease, and one case of metastatic carcinoma, this symptom was present. This demonstrates that this phenomenon is found in other diseases and that it is indistinguishable from that seen in patients with Hodgkin's disease. It should therefore not be used as a diagnostic aid for this condition.

It does, however, have some clinical value in directing the physician to a consideration of the various diseases in which it has been reported. In patients with Hodgkin's disease, this symptom when present may be of value in focusing early attention on new areas of involvement.

LIPIDS IN THE BLOOD.—The lipids are for the most part insoluble in water, and in the blood they do not occur in the free state but are associated with each other and with proteins as complex water-soluble molecules (lipoproteins) and as emulsion particles (chylomicrons). In the post-absorptive state (a term used to define a state when neither absorption from the gut nor mobilization from the fat depots is occurring), the lipids in the plasma—fatty acids, triglycerides, phospholipids and cholesterol and its esters—are found in one or other of the two classes of lipoprotein complexes known as the α- and β-lipoproteins. These are maintained at a more or less steady concentration by processes which occur predominantly in the liver. When absorption of a fatty meal occurs, additional lipid, almost entirely in the form of chylomicrons, enters the blood stream from the thoracic duct and causes a transient increase in the concentration of total lipid. The chylomicrons consist predominantly of triglyceride, but they also contain a small proportion of cholesterol and phospholipid, and in the blood they are apparently stabilized by a surface layer of protein (Frazer, 1949; Robinson, 1955). The form in which fat is mobilized from the depots is less well defined; it may be partly as triglyceride in lipoproteins and chylomicrons or as unesterified fatty acid. The latter occurs in the blood as a soluble complex with the plasma albumin. In general, the removal of lipids from the blood is determined by the permeability of the blood capillary membrane to the various lipid complexes or to their lipid components. However, at certain sites, cells in contact with the blood, such as reticulo-endothelial cells or possibly hepatic parenchymal cells, may be able to take up lipids directly.—J. E. French, D.M., D.Phil., B. Morris, B.V.Sc., D.Phil., and D. S. Robinson, M.A., Ph.D., Removal of Lipids from the Blood Stream, *British Medical Bulletin*, September, 1958.

LOW-SODIUM DIETS—PHYSIOLOGICAL ADAPTATION AND CLINICAL USEFULNESS

Thaddeus S. Danowski, M.D., Pittsburgh

Meneely[1] and others have pointed out that the practice of adding sodium chloride to our diet is largely and perhaps entirely based on an acquired taste. It has been suggested that the use of salt as a condiment began after its introduction as a preservative of meats and other perishables. In the history of man, this event appears to have coincided with the establishment of semipermanent abodes in contrast to the previous nomadic existence. The evidence in support of this view is inferential and is based largely on the fact that the word for salt does not appear in the language of any tribe prior to the establishment of settlements. On the other hand, it should be pointed out that animals seek out springs which contain this salt. In the adult animal, at least, this may be presumed to be a matter of taste.

Adjustments to Sodium Restriction

Irrespective of whether man's taste for sodium chloride meets a fundamental physiological need or is acquired, the fact remains that mammals possess an effective means of conserving sodium and chloride during periods of total deprivation of these electrolytes. Thus, the institution of a sodium-free regimen promptly evokes a marked reduction in the renal output of this ion in the urine to levels approximating zero[2] and reduces the sodium content of sweat and saliva.[3] These levels can then be employed as a measure of the efficacy of sodium restriction. This restriction even augments the already high tendency to absorb sodium from the portions of the gastrointestinal tract caudad to the stomach.[4] This conservation is mediated largely and perhaps entirely through the adrenal cortex and particularly through the most potent of the sodium-conserving steroids, aldosterone. Other adrenocortical steroids may, however, play a role. Higher centers probably participate in this regulation in view of the demonstration that some unidentified portion of the brain influences aldosterone output,[5] that, in occasional cerebral disorders, sodium wastage occurs, and that antidiuretic hormone, under certain circumstances, exerts a natriuretic and chloruretic effect.[6] This last point is controversial, however, and requires various qualifications that are too extensive for inclusion in this review.

Only a few observations concerning the effects of sodium restriction on body composition are available, and their value is compromised by the usual limitations in such measurements and by the fact that the prolonged studies have been conducted only on ill patients.[7] Under these conditions, a slight decrease in extracellular sodium and a diminution of the extracellular space and the plasma volume usually occur. Many patients on a sodium-restricted regimen, and especially those on a rice diet, lose weight. This weight loss represents a decrease in extracellular volume, a loss of body fat, and, at least in the initial phases of the use of such diets limited in protein, a loss of body protein.

Clinical Use of Sodium-Restricted Regimens

In Congestive Heart Failure.—For at least a half-century,[8] the recognition of a diminished ability to excrete ingested sodium in congestive heart failure has provided a natural basis for sodium restriction in the prevention and treatment of edema. The once lively controversy as to whether such limitations in sodium output are the result of diminished filtration or increased tubular reabsorption of sodium has quieted down with the demonstration that both factors may be operative,[9] and it is now succinctly summarized in the phrase "glomerular-tubular imbalance." The practical issue remains: When and to what degree must sodium restriction be practiced? It seems wise to institute a diet low in sodium in all cases of congestive heart failure, prophylactically if for no other reason, even though effective control of edema may be achieved by diminishing physical activity, by administering digitalis and diuretics, and by related measures that correct the fundamental defect in congestive fail-

---

From the University of Pittsburgh School of Medicine.

ure, that is, the disparity between the needs of the tissues and the ability of the heart and circulation to meet these needs. The degree of restriction can be modified in time, however, in accord with the effectiveness of the other variables in the treatment program. In some patients a diet containing 800 mg. of sodium may suffice. In others, rigid restriction to 30 or 50 mg. of sodium fails to control or correct an increasing edema.

In Cirrhosis with Ascites with or without Edema.—Similarly, in cirrhosis with ascites and peripheral edema, the degree of sodium interdiction that is necessary is determined by the effectiveness of other measures designed to improve the renal output of this ion. Thus, replenishment of circulating colloid by plasma, human serum albumin, or plasma substitutes may induce a diuresis. Relief of increased intra-abdominal pressure by abdominal paracentesis or diuretics can diminish the tendency to reaccumulate sodium excesses in some patients. In others, none of these measures proves effective unless improvement in the underlying hepatic disorder is achieved.[10]

In Renal Diseases with Edema.—Whenever weight gain, pitting edema, or hypertension are present in acute glomerulonephritis, it is wise to restrict sodium as much as possible. The need for absolute interdiction appears less clear in the milder attacks when it is remembered that patients can pass through the entire episode without recognizable symptoms or signs. However, since the dangers of unrestricted sodium intake are definite in certain patients (hypertension, convulsions, actual or simulated congestive failure, and pulmonary edema[11]), it is best to practice salt restriction in all patients, irrespective of the severity of the attack.

In subacute glomerulonephritis characterized by a nephrotic syndrome with anasarca, only a minority of the patients control their edema on sodium restriction alone, but if restriction is not practiced routinely, the degree of edema increases. In some of these patients, however, cancellation of the low serum albumin values alone may produce a diuresis.[12]

In chronic nephritis, most patients show no clinically significant ability to dispose of sodium loads.[13] In view of this fact, the question of sodium restriction as a prophylactic measure in all cases of chronic nephritis is difficult to answer categorically. Opinions vary concerning the possible adverse effects of sodium restriction upon renal function. It is true that decreases in effective renal blood flow, in glomerular filtration, and in maximum tubular function are often recorded during the low-sodium and protein-adequate regimens, but, in the experience of Page and Corcoran[14] and of others, these are usually not of clinical significance. It is our custom to advise patients with chronic renal disease who have no edema to decrease sodium intake by avoiding high-salt foods and to employ salt substitutes as condiments. In some patients with severe hypertension, more rigid sodium restriction is prescribed, in the hope that the course of the vascular component of the disease will be retarded.[14] If the renal failure is accentuated, the patient is returned to a more liberal ration of sodium. The rare, true sodium-waster should, however, be kept in mind in limiting sodium intake in any patient with renal disease. Once edema appears, salt-losing nephritis can be discarded as a possibility.

In Treatment of Hypertension.—The advent of effective antihypertensive drugs has decreased the interest in, and the use of, low-sodium regimens in the therapy of hypertension. However, in a minority of patients with blood pressure elevations, restriction of the sodium intake to 200 mg. per day or less is followed by a decrease in readings toward or to normal.[14] The program should be followed for four to six weeks before deciding that the patient will not respond.

In Toxemia of Pregnancy.—Though detailed observations on body fluid changes in normal pregnancy and in toxemia that are based on the newer techniques are just beginning to accumulate, they support the rationale of the time-honored restriction of sodium in any pregnant woman who develops hypertension, proteinuria, or edema. Irrespective of whether these clinical manifestations in a particular patient represent toxemia or some other incidental form of cardiovascular-renal disease such as glomerulonephritis, a low-sodium diet is proper therapy. General application of this view undoubtedly played a major role in decreasing the incidence of toxemia of pregnancy.

In Low-Salt Syndromes.—Some comments are in order concerning particularly troublesome forms of the low-salt syndrome, that is, the presence of congestive heart failure, cirrhosis, or renal disease in the hyponatremic edematous patient. The whole subject of low-sodium syndromes and their relation to sodium restriction has been discussed elsewhere,[15] and at this time it will suffice to point out that these patients are usually not sodium-depleted. Their total sodium stores are actually increased, and sodium administration fails to restore the concentrations of sodium in the blood to normal and ultimately only aggravates the edema. Occasionally, an element of sodium depletion may be superimposed upon this form of hyponatremia. This seeming contradiction is resolved if it is recalled that these instances of hyponatremia fall into the so-called new steady state category. Alterations in the volume, composition, and distribution of water and sodium, either as a result of the underlying disease or possibly the therapy, are perpetuated by a new setting or a relative inefficiency of the homeostatic mechanisms. Sodium restriction, except as a measure that prevents further accumulations, is invariably ineffective. The very low concentrations of sodium in the urine, even before the institution of sodium restriction, are in keeping with the high output of "sodium retaining factor" that is largely or entirely aldosterone.[16] Even if the entire intake of sodium is cut off, a diuresis does not occur. Occasionally a patient will respond to expansion of the plasma volume with colloids, and it has been suggested that restriction of water intake is beneficial. All attempts should be made to correct the underlying disease of the heart, liver, or kidney. No great amount of hope in sodium restriction is justified, and the prognosis for these patients as a group is poor; in our experience one-third to one-half die.[15]

TABLE 1.—*Sample Diet* Containing 50 Mg. of Sodium*

*Supplemented with iron and vitamins and containing 2,644 calories.

During Adrenocortical Steroid Therapy.—Diets extremely low in sodium (30 to 50 mg.) are completely effective in preventing the sodium accumulation that accompanies the use of corticotropin (ACTH), cortisone, and hydrocortisone.[12] As a matter of fact, in previously edematous patients a diuresis may occur during the course of such treatment. In our experience, such diets are well tolerated by children, and hospitalized adults abide by the regimen without undue distress for months. Such marked sodium restriction does not prevent the steroid-induced rise in blood pressure observed in some three-quarters of such patients, nor does it cancel the tendency to hypokalemia and alkalosis.[6] Potassium supplementation is usually not necessary, since the low-sodium diets already contain some 150 mEq. of this ion.

Practicalities and Hazards of Low-Sodium Diets

Tables 1, 2, 3, and 4 indicate constituents that may be included in diets containing 30, 50, and 200 mg. of sodium.[6] Though expressed as sodium chloride, the actual chloride content of these diets is not known. The acceptability of such diets is largely dependent on the benefits they confer on the patient, on the ingenuity of the dietitian or housewife, and on the use of sodium chloride substitutes. A number of useful volumes on low-sodium cookery are available for this purpose. If salt substitutes are used in conjunction with diets limited in sodium, their composition should be scrutinized when potassium restriction is also necessary. Iron and vitamins must be included in all these regimens if low-sodium diets are to be used for more than a few days.

The rice diet introduced by Kempner[17] or a low-sodium, dialyzed milk formula fortified with carbohydrate may also be used for purposes of sodium restriction.[6] The rice diet is low in protein (25 Gm.), but this quantity permits attainment of nitrogen balance. Monotony, however, is a major problem with both of these regimens.

In some patients, the sodium content of the diet may be liberalized somewhat by intermittent use of diuretics and by prescribing the acidifying forms of the cation exchange resins. The latter should be given in dosages of 40 to 60 Gm. each day for several days at a time, the potassium-containing form should be avoided if potassium accumulation is a problem.[18] The ammonium types should not be employed in patients on the verge of hepatic coma.

TABLE 2.—*Other Constituents Used in a Diet,* Containing 50 Mg. of Sodium*

Beverage		Coca-cola, fruit juices, sodium-free dialyzed milk, water
Cereal	Cooked:	Cream of wheat (plain), corn meal, oats (rolled), Ralston, Wheatena
	Dry:	Puffed rice, puffed wheat, shredded wheat
Fruit	Fresh:	Any fresh fruit except cantaloupe
	Canned:	Applesauce, apricots, cherries, grapes, peaches, pears, pineapple, prunes, dates, figs (raw or canned), lemon juice
Vegetable		Asparagus (fresh or frozen), beans (dry, navy, fresh or frozen green, fresh lima, soy), corn on cob (fresh), cranberries, cucumbers, eggplant, lentils, lettuce, onions, peas (fresh), peppers (green), potatoes, tomatoes, rice
Miscellaneous		Bread (unsalted), butter (unsalted), casec, cinnamon, cloves, cocoa (American process), coconut (fresh or unsalted), cornstarch, flour, honey, jelly, macaroni, mustard, Necco wafers, nuts (unsalted), peanut butter (unsalted), pepper (black), popped corn (unsalted), vinegar, spaghetti, Spry, sugar

*Variety has been added to diet by use of readily available proprietary handbooks describing use of protein supplements modified, when necessary, by eliminating those ingredients that would increase sodium content of diet above 50 mg. All foods to be cooked without addition of salt. Diet must be supplemented with iron and vitamins.

The chief hazard of sodium-restricted diets is the depletion of the sodium ion. Depletion may occur abruptly as a consequence of extrarenal losses of this ion in diarrhea, vomiting, other gastrointestinal drainage, or sweating. Circulatory collapse or water intoxication with convulsions may then result. Under such circumstances, the regimen should be discontinued immediately and sodium salts and plasma or plasma substitutes administered. In addition, patients on exchange resins may develop potassium depletion and deficits of multivalent cations such as calcium and iron.[18] This can be avoided by interrupted programs of administration.

Summary and Conclusions

In any patient with edema, the therapeutic goal is the attainment of a negative balance of sodium chloride and water. Regimens restricted in sodium either in the form of the rice diet, dialyzed milk formulas, or diets containing 30, 50, 200, or 800 mg. of sodium chloride often result in a diuresis in patients with congestive heart failure, cirrhosis, renal failure, or toxemia of pregnancy. In prolonged usage, sodium-restricted diets are monotonous and prove burdensome. It should be remembered that some patients respond to slight or moderate sodium-restricted diets, especially if the underlying cause can be corrected. Cation exchange resins in the appropriate cycle and diuretics may prove to be effective adjuvants in such patients.

TABLE 3.—*Diet* Containing 200 Mg. of Sodium*

Beverage	Low-sodium milk (2 cups), tea, fruit juice, Coca-cola, cocoa (American process) made with low-sodium milk or water
Bread	Yeast bread or rolls made without salt or milk, as desired
Cereal	Cooked, without salt, as desired; puffed wheat, puffed rice, shredded wheat
Fat	Any unsalted fat, as desired
Fruit	As desired (limit cantaloupe and dried figs to 1 serving)
Meat or alternate †	Egg (limit to 1 a day), meat or fish (5 oz. cooked weight), any fresh meat (except kidney, liver), any fowl, any fresh fish, oysters
Potato or alternate	As desired
Seasoning	Any except salt
Soup	Cream soups, made from allowed foods
Dessert	Made from allowed foods, such as unsalted fruit pie, fruit tapioca, cornstarch pudding
Sweets	Jam, jelly, honey, maple sirup, white sugar, as desired
Vegetable	1 cup of fresh or frozen or canned without salt; asparagus, green beans, wax beans, lima beans (fresh),‡ navy beans, peas (fresh),‡ tomatoes, soy beans, broccoli, Brussels sprouts, cabbage, carrots, cauliflower, rutabagas, turnips, parsley, cowpeas, eggplant, endive, lentils (dry), squash, corn, lettuce, parsnips

* No salt, soda, or baking powder used in the preparation of any foods.

† No meat juices, broths, or gravies are to be used.

‡ Frozen lima beans and peas are salted.

* Supplemented with iron and vitamins and containing 1,490 calories.

There exists, however, a group of edematous patients with low levels of sodium in their serum in whom none of these measures proves effective. In these forms of the low-salt syndrome, the mechanisms regulating the concentration, volume, and distribution of body fluids are operating at new settings, or homeostasis is disturbed. These have been called "new steady states." The edema does not respond to sodium restriction, because the renal conservation of filtered sodium is virtually complete as a result of increased amounts of sodium-retaining factors that consist largely or entirely of the mineral-regulating adrenocortical steroid, aldosterone. In such patients, the concentration of sodium cannot be returned to normal by sodium administration. The chief therapeutic attack should be directed at the underlying disease of the heart, liver, or kidney. In some patients, however, expansion of the plasma volume may control the edema, and it has been suggested that water restriction may be of benefit.

Rigidly restricted diets may prove beneficial in the control of hypertension, though antihypertensive drugs are more effective in this regard. Sodium-restricted diets are also beneficial as a prophylaxis in patients prone to develop edema, as in pregnancy or in those receiving adrenocortical steroids or other agents that lead to sodium retention.

The hazards of sodium restriction are those of sodium depletion, usually via extrarenal routes, with circulatory collapse, renal failure, and a tendency to convulsions resulting from the attendant hyponatremia. The clinician must be alert to the premonitory signs of the salt depletion type of low-salt syndrome. These may consist of mental changes such as confusion, decreases in urine output, or a rising level of blood nonprotein nitrogen or blood urea nitrogen.

The effectiveness of a sodium-restricted regimen may be judged by the patient's responses, such as diuresis, weight loss, decrease in edema, or improvement in clinical status; however, the failure to observe any of these changes does not necessarily mean the patient is not following the diet assiduously. Measurements of urinary sodium output may detect incomplete adherence in those patients in whom secondary aldosteronism is not pronounced. The use of low-sodium diets requires a definition of the mechanisms operative in any particular instance of edema, an appropriate degree of sodium restriction, the use of adjuvants such as exchange resins and diuretics, and an awareness of the adverse effects of sodium depletion.

THE CAROTID SINUS.—The carotid sinus is a bulbous dilation of the first portion of the internal carotid artery. The tunica adventitia of the sinus is thicker than the tunica adventitia of the rest of the artery, and contains special nerve cells or "nerve receptors" situated between the layers of collagen. Pressure-sensitive fibers of the glossopharyngeal ("nerve of Hering"), hypoglossal, vagal, and cervical sympathetic nerves are generally believed to carry afferent impulses to the vasomotor and cardio-inhibitory centers in the reticular formation of the medulla. From here the impulse traverses the central synapses and, after crossing, passes contralaterally as a motor impulse toward the periphery through widespread autonomic nerve pathways, namely the vagus, the sympathetics, and the central motor pathways. The type of response, therefore, depends primarily on the direction of the motor responses induced. Normally, the carotid sinus is concerned with regulation of blood pressure and cardiac rate, and mechanical pressure will cause slight slowing of pulse with concomitant slight fall in blood pressure. In patients in whom the carotid sinus reflex mechanism is abnormally sensitive, however, mechanical stimulation produces marked symptoms.—R. E. Roscoe, M.D., C. P. Faller, M.D., and K. E. Quickel, M.D., The Treatment of the Carotid Sinus Syndrome, *The American Journal of Cardiology,* September, 1958.

Coffins, Costs, and Care

"I think one reason hospital costs are going up and have gone up is that the patient now comes out on his own two feet, instead of in a coffin."

That is the opinion of U. S. Congressman Thomas B. Curtis of Missouri. He goes on to say, "People get an awful lot more for one dollar of medical and hospital care today than they ever got before." Curtis believes that the increased cost of living today indicates, in many cases, an increase in the quality and standard of living. Among these increases are better medical care and longer life.

These same years of added life, however, are levying a tax of inflation on America's older citizens, thus creating an economic problem, the Congressman said. His suggested solution: Modern nursing homes which can care for the aged at a reduced rate.

Government, Curtis said, will always play an active role in solving social problems, but he stresses the individual's role in bringing about improvements and he urges medicine to take an interest in governmental activities at the "grass roots" level.

In a final word of advice to physicians assembled at the A. M. A.'s recent PR Institute, Curtis said: "Keep a broad outlook, get the word out on specific issues, and give Congressmen the benefit of your beliefs and honest debate."

Doctors Start Acting to Foster Scholarship Among Teenagers

Academic achievement has become a national resource—and physicians of at least one county medical society are putting those words into action.

Within a few weeks, thanks to leadership by members of the Adams County Medical Society at Quincy, Ill., another incentive to improved high school scholarship in that community will be established. The first annual cash awards of $100 each and engraved gold keys will be presented to the boy and the girl who earned the highest grades—with emphasis on academic subjects—during the past year in the six high schools of Quincy and Adams county.

This so-called Doctor's Plan of awards, made possible by an anonymous Quincy physician, is the latest of several steps taken under medical society initiative in recent years to counteract a public school tendency of promoting sports and extracurricular activities at the expense of book learning. The growing movement in Illinois was inspired by a group of Fort Dodge, Iowa, physicians who launched a campaign in 1954 "to promote and popularize scholarships as the principal objective of schools." Those doctors created the Fort Dodge Foundation for Academic Achievement, which honors top scholars of the community's two high schools at a banquet each spring.

Two years after the successful Fort Dodge effort began, the Kiwanis Club of Quincy (which has nine physician members) and the club's Swanberg Kiwanis Foundation (brain child of Dr. Harold Swanberg, a radiologist in the community) organized the Quincy Major Learning Program—"dedicated to a college education for every talented high school graduate of Quincy and Adams county." The president of the foundation is Dr. Warren F. Pearce, an internist.

Through the spoken and the written word, that program is hammering home the point that a "crisis in education" (see box) could cause this nation to lose "the cold war of the classrooms." Physicians, teachers, businessmen, parents, local government officials, Kiwanis Club members in many fields of endeavor—all have been intent upon doing everything possible to identify superior and talented high school students and to guide and motivate them to secure a college education. All have been emphasizing the fact that presently half of this nation's brightest high school students do not go to college. Those were the words and aims in Quincy. So far, these are the actions, too:

—The Adams County Medical Society has established annual awards of certificates for up to 10% of the boys and 10% of the girls of local high

Fig. 1.—These students, competing for college scholarships in Illinois, personify the successful efforts of many individuals and groups—including physicians and their medical societies—to promote academic achievement as a higher priority goal for teenagers.

What Others Say About Our "Crisis in Education"

"In [Soviet] education the spirit is a race for knowledge, for supremacy in a way of life and world leadership. They are convinced that time is on their side and they can win world supremacy through education and hard work. We as a nation cannot afford to disregard the challenge imposed upon us by the Russian race for knowledge." —Dr. Lawrence G. Derthick, U. S. Commissioner of Education

"There is no substitute, in preparatory education, for the rigorous study of fundamentals in mathematics, English, a foreign language, science, history and social studies."

—Dr. Milton Eisenhower, President of Johns Hopkins University

"Every [high school] student must take four years of English, four years of social studies, two years of mathematics, two years of science."

—Dr. James B. Conant, former President of Harvard University

"English, foreign languages, science, mathematics, and history are the things that every high school student needs. All of us have to live in a modern world where things are fundamental. All are citizens and must use intelligence in making decisions, otherwise the nation is headed for disaster."

—Dr. Arthur Bestor, Professor of History, University of Illinois

school graduating classes who achieve highest grades (with emphasis on performance in academic subjects). The certificates are presented at joint luncheon meetings given by the medical society and the Kiwanis Club.

—Last summer 82 local high school teachers attended workshop sessions on guidance counselling, conducted by Western Illinois University and financed by grants from the Quincy Board of Education and the Swanberg Collegiate Educational Fund of the American Medical Writers' Association.

—Scholarship opportunities, particularly those offered by the State of Illinois (fig. 1) have been publicized broadly in the Quincy area as added incentives to academic achievement. Last month the Quincy Major Learning Program scheduled four television, school, and luncheon meeting talks in Quincy for the associate director of the Illinois State Scholarship Commission.

—Literature on scholastic incentives and current scholarship opportunities is being sent free of charge to parents in Adams county and to high school students.

—Local high school seniors who score high in National Merit Scholarship tests are praised in published items, such as one distributed last month under the headline "Quincy Is Proud of Four Quincy Senior High School Seniors."

—A program is under way to acquaint other county medical societies and community organizations with the great public service potential of projects similar to the ones in Fort Dodge and Quincy. Under this program, for example, Dr. Swanberg is scheduled to address a group of community leaders in Kirksville, Mo., later this month (Dec. 18). In addition, an exhibit of the Quincy Major Learning Program has been shown before several local and national Kiwanis groups, the Illinois State Medical Society, the Mississippi Valley Medical Society, the American Medical Writers' Association, and other organizations.

The Broader Picture

Already, these activities sparked by physicians in Iowa and Illinois are being reinforced on a national scale. Last March, for example, the Commission on Research and Service of the accrediting North Central Association of Colleges and Secondary Schools received a grant of $174,000 from the Carnegie Corporation of New York to conduct a two-year research project whose purpose is identical to that of the pioneering medical society efforts: "To find, develop, and implement procedures and programs in secondary schools which will identify, guide, and motivate as many as possible of the superior and talented students in all fields of learning to desire, plan for, and acquire a thorough college education."

Meanwhile, physician concern generally in public school education is rising on an individual basis throughout the nation. This is shown in the latest biennial survey report of the A. M. A. Council on Medical Service, which indicates that more and more physicians are serving on their local school boards. Such community service, of course, is both typical and traditional for the medical profession (see Medicine at Work, THE JOURNAL, March 16, 1957).

All this is gratifying to Dr. Swanberg. He says: "What a wonderful achievement it would be for the nation if county medical societies all over the country would give high school academic scholarship awards. How well we succeed in educating each child to the maximum of his inherent potential will ultimately determine his fate and our own."

Committee on Indigent Care Plans Study of State Programs

How well are the personal health needs of the indigent and medically indigent being met in your state? Is there an adequate plan for provision of indigent care, or does it depend in great measure on the charitable impulses of physicians?

These are the kinds of questions the A. M. A. Committee on Indigent Care of the Council on Medical Service will be asking constituent societies early next year in an effort to up-date its continuing study of indigent medical care plans begun in 1951. Discussion of the proposed questionnaire took place at a Committee meeting in Chicago Nov. 2. In 1955, the Committee published case studies of indigent care operations in 18 communities selected to indicate variations in approach and medical society participation.

In 1956, the House of Delegates adopted the Committee's "Guides for Medical Societies in Developing Plans for Tax-Supported Personal Health Services for the Needy." How well these guides are understood and how widely they are being used are two areas the new study will cover.

First recipients of the questionnaire will be Committee members who expect to gain insight into the problem by studying the situation in their own states. Field studies of selected areas may begin next spring.

Bill for Indigent Care Anyway?

"Physicians should always bill for indigent care services, even if they do not expect payment, because not to do so is to give public agencies supporting such services an untrue picture of the cost of such care."

This opinion was expressed recently by a participant at a meeting of the A. M. A. Committee on Indigent Care. "Agencies charged with providing medical care for the indigent balk at the cost of providing Blue Cross, Blue Shield, or other kinds of prepayment plans on the ground that present methods of providing medical care are cheaper," he said. "They aren't really cheaper, they just appear to be because many physicians do not bill for services they perform for indigent patients."

Chairman of the Committee on Indigent Care of the Council on Medical Service is Dr. John F. Burton of Oklahoma City. Other members are Drs. A. J. Bowles of Seattle; I. Jay Brightman of Albany, N. Y.; E. P. Coleman of Canton, Ill.; Wesley W. Hall of Reno, Nev.; E. A. Ockuly of Toledo, Ohio; and Dean W. Roberts of Chicago. Consultants are Mr. R. M. Hilliard of Chicago and Mr. Nelson B. Neff of Reno. Mr. George W. Cooley is Staff Secretary.

Five U. S. population centers are known to have central information and referral services for the chronically ill, and the Committee on Indigent Care plans to publish a report on their history, administration, operation, and services later this winter.

The five are located in Chicago, Milwaukee, Cleveland, San Francisco, and Essex County, N. J. These organizations assemble, study, and make available information on existing resources and facilities for the chronically ill. They also have the potential for determining unmet needs, developing coordinated programs, and assisting others in planning facilities and programs.

Planning for Indigent Care Is Obligation of Local Societies

"The medical profession should guide the development and operation of the medical aspects of [indigent care] programs to assure their remaining within proper bounds," the Committee on Indigent Care stated this week in its annual report submitted at the Clinical Meeting in Minneapolis.

To accomplish this, the Committee again urges that state and county medical societies take an active part in the planning and operation of such programs. Its report states: "The Committee plans to gear its future activities to the needs of the various states, providing them with necessary information on laws and existing programs, advice, and consultation when requested."

The Committee is planning more meetings, similar to those offered in the past, at which representatives of state societies will gather to compare and perhaps work out their problems together with the Committee and federal bureau help. Several state associations, according to the Committee, have taken an active part "not only in planning indigent medical care programs, but even in stimulating legislatures and governmental officials to undertake the study of state needs and facilities, preparatory to such programs."

"The Committee feels that there will be a continually increasing interest in medical services in welfare programs," the report continues. "It behooves medicine to work with welfare agencies and to see to it that proper and adequate programs are developed.

"This recommendation does not apply only to those areas where the medical profession receives payment from public funds. Even when the physicians' services are provided through the charity of the individual physician in his office or while he is on staff service at the local hospital, the medical society should still maintain an active interest in the goals, the methods, and the operation of the over-all medical care program."

Five Health Groups with One Aim—Improve Patient Care

What are some of the problems which arise when a New Yorker is moved from a hospital to a convalescent home? How might properly-worded booklets help disturbed patients in South Dakota adjust themselves to hospital routines? How many Rhode Island patients will benefit from knowledge gained by physicians, nurses, and hospital administrators at joint conferences on infections and on rehabilitation techniques?

These and related questions are being answered daily through the activities of special committees in hundreds of hospitals throughout the nation. A pioneer in this movement is the 10-year-old National Joint Commission for the Improvement of the Care of the Patient, which met several weeks ago in New York City to review achievements of similar commissions in 25 states, to elect officers, and to discuss such matters as development of hospital administrators, legal liability in hospitals, and medical house staff orientation. Named chairman for the coming year was Rev. John J. Flanagan, S. J., executive director of the Catholic Hospital Association. Elected as A. M. A. representative to the commission's executive committee was Dr. Cleon Nafe of Indianapolis, a member of the A. M. A. Board of Trustees. Miss Margaret Giffin, director of hospital nursing for the National League For Nursing, was reelected secretary.

The National Joint Commission was created in 1948 as the result of an A. M. A. House of Delegates report. It is organized on the belief that professional people whose work is interrelated and mutually dependent can serve the patient more effectively when there is opportunity for cooperative planning, free discussion of problems, and evaluation of coordinated activities. These joint groups at the national, state, and hospital levels are designed to be advisory only—neither legislative nor setting policy for the parent organization. Members of the National Joint Commission represent the American Hospital Association, the American Medical Association, the American Nurses' Association, the National League for Nursing, and the National Federation of Licensed Practical Nurses. (The New York session last Oct. 24 and 25 was preceded by a meeting of the A. M. A. Committee on Nursing.)

Following are sample activities of the state commissions as reviewed at the National Joint Commission conference:

Arizona—"Gave assistance with legislation pertaining to Nursing Practice Act and intravenous therapy."

Connecticut—[illegible] education costs; legislating for nursing scholarships; developing a licensed practical nurse program.

Kansas—"Acquainting" Blue Cross and Blue Shield with nursing needs and resources.

Nebraska—Presenting programs on rehabilitation and nursing homes.

New York—Promoting regional conferences patterned on the Governor's Conference on Problems of Aging; studying use of intensive care units (see Medicine at Work, THE JOURNAL, April 26, 1958).

South Dakota—Sponsoring workshops on disaster planning, diversional therapy and control of visitors to hospitals; compiling booklet for patients on the "why's" of hospital procedures (see Medicine at Work, THE JOURNAL, Dec. 1, 1956).

Texas—Publishing a health careers booklet, "Deep in the Health of Texas."

Washington—Recommending a permanent advisory committee on drugs and therapeutics.

Extension of the National Joint Commission's aims to state and hospital units was begun five years ago. A similar step was taken this year when the A. M. A. Board of Trustees and the A. H. A. Board of Trustees endorsed a recommendation that every hospital create a Joint Conference Committee made up of representatives from its medical and governing groups "in order that there be a mutual understanding of each other's activities and problems" (see Organization Section, THE JOURNAL, Nov. 1, 1958). That recommendation now is being adopted in hospitals the country over. It, too, inevitably will serve to improve the care of the patient as the health professions keep pace with modern needs.

For, as Peter B. Terenzio, director of the Roosevelt Hospital in New York City, remarked to the National Joint Commission at its October meeting: "Originally, hospitals were places to die, not to get well. They were places for the poor sick, not for sick people generally. Today's hospital is for the care of the patient—everything else is secondary."

Two Minnesota Societies Aim at Home Care for the Chronically Ill

Medical societies in two rural Minnesota counties have joined with other groups in programs to provide chronically ill and disabled patients with home nursing and rehabilitation services.

Wright County's medical society joined a citizens' committee which is cooperating in turn with the state medical association's committee on chronic disease and with the state health department to conduct a house-to-house survey. By late summer, the combined volunteers had recorded 155 persons confined to their homes by chronic illness, 49 of whom were previously unknown to county authorities. More than two-thirds of the number were

65 or older. Forty per cent were suffering from diseases of the heart or blood vessels.

Other groups with representation on the citizens' committee include the board of public health nursing and the county welfare board.

Wright County has already begun a layman's course in nursing care for the homebound. Other recommendations growing out of the survey include:

—Establishing rehabilitation nursing as a service of the county public health program.

—Offering outpatient physical therapy at the community hospital.

—Encouraging a handicraft and recreation center for the aged and the handicapped.

—Assembling a roster of persons qualified to offer home nursing care.

—Establishing evaluation techniques on patient rehabilitation potential.

Seventy miles away, in Steele County, the board of commissioners, cooperating with the county medical society and the public health nursing board, has established a pilot home nursing care program for the homebound ill or disabled.

A licensed practical nurse gives supervised care to patients under a doctor's care. Cost of the visits—up to $3—depends on ability to pay. The program is partially subsidized by the Minnesota department of health.

Query 313 on Medical Care Ideas

The question: Taking everything into account, who do you think is likely to get better medical care—the person in a medical plan in which he chooses the doctor, or the person in a medical plan in which the plan chooses the doctor?

The answer: Seventy-six per cent of the 313 persons interviewed in a national survey said they felt that better care would result if the patient, rather than the medical plan, selected the physician.

Those figures are reported as results of a representative sample of the adult population by Opinion Research Corporation for the American Medical Association.

The results, according to the Opinion Research Corporation, also indicated that a majority of those interviewed:

—Said they felt continuity in a doctor-patient relationship was an important factor in good medical care.

—Said they preferred to choose their own physician even if it meant paying part of their own medical costs.

Detailed reports on the findings were published in two issues (Oct. 20 and Nov. 3) of *The A. M. A. News.*

New Facilities Being Used in Fight Against Alcoholism

Two new facilities to aid those struggling to defeat alcoholism (see Medicine at Work, THE JOURNAL, July 19, 1958) have come into being in recent months. In New York City, three men with $4 and a personal knowledge of the horrors of alcoholic addiction opened Fellowship Center in an 88th Street hotel. And in Birmingham, the Alabama Commission on Alcoholism opened the doors of its first outpatient clinic.

The aim in New York is "to bridge the gap between the attainment of sobriety and a full, useful life." Alabama's stated objective is "to assist (the patient) to regain, not only sobriety, but better health and greater happiness by means of a more ideally adjusted personality."

The Fellowship Center is an outgrowth of one man's self-dedication at a time when he was in a New York jail, a despairing alcoholic. It took five years, but last January, Buford Peterson and two other men who had known similar suffering pooled their petty funds and their impressive faith to rent 14,000 feet of space in a small hotel.

With use of money lent or contributed to the work, Fellowship Center functions primarily to rehabilitate the alcoholic whose home life has been shattered and whose addiction has frequently led to his being imprisoned. Peterson, an alcoholic for 20 years, says: "Sobriety, when first gained, leaves one in a state of weakness, confusion, indecision. Without a helping hand, a lapse looms dangerously."

The Center offers immediate physical necessities, bolsters "sick" morale, helps find work, explains the victim's plight to his family, and pools the wisdom of representatives of public and private agencies.

Alcohol and its influence on personal well-being is being approached on two other levels.

—A seminar on counseling the alcoholic was presented for area clergymen Oct. 24 by the Chicago Committee on Alcoholism. Speakers included Dr. Patrick Israel, psychiatrist and psychiatric director of the committee, and Granger Westberg, professor of religion and health at the University of Chicago.

—In February, an organization to discourage drinking by adolescents—Allied Youth, Inc.—will ask physicians in the U. S., through local chapters, to provide expert discussion leadership at meetings of teenagers. The high school-aged youngsters are encouraged to learn the nature of alcohol with the idea that this will encourage abstention.

Dr. R. C. Boyer, medical director of the New York City Department of Correction, is a member of the board of directors. Other board members and advisors include religious leaders, judges, social workers, and parole officers.

Alabama's establishment of an outpatient clinic—as reported in the *Journal of the Medical Association of Alabama*—marks a change in policy. In 1945, the state created a Commission on Education with Respect to Alcoholism, emphasizing the educational approach. Last year, however, the legislature gave the commission an annual appropriation of $150,000 and called for the establishment of outpatient clinics.

Staffed by a team that uses the multidisciplinary approach found effective in other states, the first clinic accepts patients on self-referral or those who come at the suggestion of physicians, family, friends, clergymen, social agencies, or Alcoholics Anonymous.

Director of the clinic and senior physician is Dr. Edwin M. Fuchs, resident psychiatrist since 1955 at the Philadelphia General Hospital. He is assisted by a part-time internist, a part-time psychologist, and two full-time psychiatric social workers.

New Look in Christmas Gifts

A novel approach to the idea of Christmas giving has been taken by the Arizona Medical Association. It recently approved a resolution asking that the usual donors of small holiday gifts to physicians replace them with contributions to the American Medical Education Foundation. A new AMEF newsletter, "The Foundation," reports that such donations would be expected to replace promotional calendars, desk sets, pens, and other items ordinarily sent to doctors.

The newsletter also reported:

—A gift of $1,000 from the Alaska Territorial Medical Association shortly after statehood was approved for the Territory this year.

—Two gifts from medical societies representing proceeds of polio vaccination programs carried out on a public-service basis. A donation of $2,708 was received from the Nashville Academy of Medicine and the Davidson County Medical Society of Tennessee. Another $1,750 came from the Pueblo County Medical Society of Colorado.

—Plans for the eighth annual meeting of AMEF state chairmen to be held Jan. 24-25 in Chicago.

In the seven years since its founding under AMEF auspices, the AMEF has disbursed to medical schools more than 7 million dollars contributed by physicians and other donors (see Medicine at Work, THE JOURNAL, April 20, 1957).

Case of the Disappearing Rental Illustrates Question in Ethics

The Case of the Druggist and the Disappearing Rental is not a new Whodunit, but it forms an example of the type of ethical problem the A. M. A. Judicial Council feels should be handled by the county society.

The case, cited as part of the Council's annual report submitted this week at the Clinical Meeting in Minneapolis, involved a proposed contract for office rental sent to the Council by an unnamed physician. The office space was owned by a druggist and located in the same building as his own drugstore. Rental was to be $1,000 a month, but would be reduced on a sliding scale, depending on the number of prescriptions filled for the doctor's patients.

The Council's report said: "If the physician sent the druggist an average of 10 prescriptions a day the rent would be $900 a month; if he sent 20 a day, rent would be $800. With each daily increase of 10 prescriptions by the physician, the druggist agreed to reduce the monthly rental by $100 until the rental would be $1 a month if the physician sent the druggist an average of 100 prescriptions a day."

Is this unethical? It certainly is according to the report, which also stated: "The component society is an autonomous group and as such one of its principal duties is to apply ethical principles. Apparently this obligation is not recognized . . . or is, at best, not accepted as a principal obligation. The Council has noted a failure on the part of physicians to turn to their county societies concerning the application of ethical principles and the failure of county societies to be more aggressive in developing a sound program of ethics."

The Council receives numerous letters containing statements similar to this: "One of the doctors on the staff of our hospital is in doubt concerning an ethical problem. Will you please advise me so I can tell the doctor what his conduct should be?"

"Why should a doctor go to a hospital administrator with a question of ethics?" the report asks. "Why should the hospital administrator accept the responsibility? How often do hospital personnel . . . resolve or attempt to resolve questions of ethics?"

The Council believes that "if medical societies fail to accept and discharge their obligations in matters of ethics others will assume these obligations by default."

The report urges "county and state societies to adopt a critical attitude toward their programs to 'uphold the honor and dignity' of the profession of medicine. These programs must be based on a sound knowledge and understanding of ethical principles." To aid societies in this regard the Council has distributed this past year representative opinions and interpretations of the "Principles of Medical Ethics," so that members now have a "collection of precedents to which they may turn when it becomes necessary to evaluate the ethical propriety of particular conduct."

Medical Leadership in Time of Disaster

"I know of no profession or group that is more dedicated to the cause of civil defense than is the American Medical Association. It is a good thing for all of us that you are, for it is with you, and all others so strategically situated, that our civil defense effort will succeed, or fail."

With these words, Leo A. Hoegh, Director of the Office of Civil and Defense Mobilization, keynoted the ninth County Medical Societies Civil Defense Conference in Chicago early last month. Attended by more than 200 persons representing 31 states, the conference offered speakers on such subjects as federal and local CD planning, biological and chemical warfare, public health disaster problems, the role of paramedical services, and reports on three disaster exercises. In addition, workshop sessions were held to discuss specific problems in mass casualty care.

Selected comments by speakers at the two-day conference—sponsored by the A. M. A. Committee on Civil Defense, Council on National Defense—include:

Dr. Carroll P. Hungate, member, Council on National Defense—"To properly handle the medical effects of nuclear weapons was, long ago, recognized as the greatest organizational challenge to American medicine in the 20th century. We are meeting this challenge, and our results are reflected in the better handling of natural disasters, new awareness of the effects of radiation in industry, medicine, research, and from atomic sources."

Col. Ingalls H. Simmons, Director, Department of Preventive Medicine, Army Medical Service School—"If you are out walking in the street when a bomb goes off, fall flat, face down, immediately. This is going to be a big American problem, because we are just too curious. Curiosity pays dividends in some ways, but at the time of a thermonuclear bomb, it certainly will not pay you to look around to see what is happening."

Russell W. Bunting, DDS, Dental Consultant, OCDM—"For the past seven years, the dentists of this country have been placed in an equivocal position. They have been told that their basic medical training, their experience with handling patients in severe pain, and their cooperation with medicine in the care of their patients makes them high priority professional personnel. But, as yet, organized medicine has made no official statement to sanction or support . . . allied professional training."

"Every home and eating place, as well as many office buildings, have several sources of emergency water supply which might well be forgotten in the confusion of a disaster," Col. Ingalls H. Simmons told those attending the ninth County Medical Societies Civil Defense Conference in Chicago last month.

Water heaters, the flush tanks of toilets, ice cube trays, water bottles, and canned fruits and vegetables packed in water are all safe and protected sources for the seven gallons per person that is the minimum weekly ration, he said. Col. Simmons is the Director of the Department of Preventive Medicine of the Army Medical Service School at Fort Sam Houston in Texas.

Dr. Gunnar Gundersen, president, American Medical Association—"I believe that every physician has a responsibility to prepare himself, and to participate in disaster planning in his community. Nurses, paramedical personnel, hospital clerical personnel, ambulance drivers, rescue workers, and others will look to the physician for guidance in performance of duties in the disaster situation. It is the physician who must coordinate the activity of these persons."

Dr. Paul S. Parrino, Director, Biophysical and Medical Sciences Office, OCDM—"It is necessary to explore the biological, physiological, and psychological factors involved in living in shelters. This is necessary to know the vital and immediate medical problems that might arise. We need to know the effects of group living in close space for long periods of time."

Disaster Plan Developed for Metropolitan Kansas City Area

A comprehensive disaster plan for the metropolitan Kansas City area is now ready for use. In reporting this fact Sept. 13 to the A. M. A. Committee on Civil Defense and regional medical representatives in Boston, Dr. Carroll P. Hungate, a member of the committee, said that workability of the plan depends on whether satellite communities accept the Kansas City mayor as head of the program and community officials as his deputies. The mayor's role in the plan had been recommended by the governor of Kansas.

The plan visualizes fire stations as centers for the organization of disaster units, which would include physicians and other health and medical personnel.

To implement its planning, Kansas City in September began a Light Rescue course open to men and women at 25 fire stations. Instruction will be headed by fire captains specially trained in the work. Other courses, planned for later dates, will include such subjects as first aid and survival.

Double-Duty Ambulance

An ambulance, like an insurance policy, is purchased with an eye toward the emergency situation, but it can be made to serve more than double duty. Proof is the eight-patient vehicle designed by Dr. Thomas F. Nevins Jr., plant physician of the Linden, N. J., refinery of Esso Standard Oil Company.

Built on a five-ton truck chassis, the ambulance has every emergency facility but is used also for mass inoculations, a safety eyeglass program, and as a mobile first aid station for the company's occupational health program.

In addition to the standard ambulance equipment, Dr. Nevins' brain child includes a 110-volt generator, a recording and PA system, gas and oxygen masks, a built-in oxygen supply, and a portable resuscitation unit with remote controls.

Perhaps best of all, the unit cost only about $16,000. "A regular one-patient station wagon type costs at least $12,000," Dr. Nevins says.

Committee Studying Mobile Units in Employee Health Programs

The role of mobile units in employee health programs and the range of services they provide are being studied by the A. M. A. Committee on Medical Care for Industrial Workers, according to the Committee's annual report submitted this week at the Clinical Meeting in Minneapolis. Units have been broadly categorized by the Committee on the basis of the following service arrangements and ownership:

—Those operated by a labor union as a fringe benefit resulting from collective bargaining for members located in numerous small plants within a state. They are staffed by a medical case worker and a clinical laboratory technician who perform tests evaluated by the physician in charge of the program. General nature of the findings is reported to the person examined and a report is usually sent to his personal physician. Companies serviced by these units have no occupational health programs of their own.

—Units which are a part of a management-sponsored program that tour company installations in several states where no plant physicians are employed. An examining physician and a technician conduct a variety of tests and immunizations. Findings are reported to the family physician and to the company's central medical office.

—Those operated by a physician-owned service and offered to industry on a contractual basis. Screening examinations are done by local physicians hired for the purpose.

—Units operated by a nonprofit organization formed jointly by management, labor, and professional groups to serve a geographic area. Industry pays a fixed amount per employee for annual multiphasic examinations. If tests reveal need for medical care, the employee is referred to his own physician.

According to the annual report, the Committee plans to study mobile units in greater detail "particularly in determining to what extent is the screening of employees for the express purpose of detecting nonoccupational diseases properly a part of an occupational health program."

Chairman of the Committee on Medical Care for Industrial Workers is Dr. Frank J. Holroyd of Princeton, W. Va. Other members are Drs. Leo Price of New York City; Edwin P. Jordan of Charlottesville, Va.; William A. Sawyer of Rochester, N. Y.; Clyde Sparks of Ashland, Ky.; Frederick Slobe of Chicago; Thomas J. Danaher of Torrington, Conn.; and Melvin N. Newquist of New York City. Staff research associate is Mr. Murray Klutch of Chicago.

CIH Works on Immunization Guide

Defining the role of industrial medical departments in the matter of immunization has posed an increasing problem in recent years—a problem for which an A. M. A. committee hopes to have an answer soon. The Committee on Industrial Health Emergencies of the Council on Industrial Health is working on a "Guide for Industrial Immunization Programs," it was reported at a meeting of the Council held Sept. 4-7 in Portland, Ore.

The Council also heard:

—That its Committee on Industrial Health Emergencies will poll 69 selected industrial health departments asking details on their handling of employee immunization during last year's Asian influenza epidemic. The survey is being made at the request of the A. M. A. Special Committee on Influenza as a part of the development of a standby program for use in future mass immunizations.

–Vice Chairman Robert A. Kehoe warn that the Council must soon be prepared to offer a statement on the principles of undergraduate training in occupational medicine.

–A discussion of plans for the 19th Annual Congress on Industrial Health to be held in Cincinnati Feb. 16-18. Theme of the congress will be "Occupational Medicine–Education, Research, and Practice."

Chairman of the A.M.A. Council on Industrial Health is Dr. William P. Shepard of New York. Vice Chairman is Dr. Robert A. Kehoe of Cincinnati. Other members are Drs. V. C. Baird of Houston; John N. Gallivan of East Hartford, Conn.; Rutherford T. Johnstone of Los Angeles; E. S. Jones of Hammond, Ind.; Lemuel C. McGee of Wilmington, Del.; Melvin N. Newquist of New York City; Paul S. Richards of Salt Lake City; Oscar A. Sander of Milwaukee; Charles F. Shook of Toledo; and James H. Sterner of Rochester, N. Y. Dr. B. Dixon Holland is Staff Secretary.

Opinions of 10,000 Lawyers Sought in Medicolegal Study

When the A. M. A. Legal Department surveys 10,000 attorneys this winter on matters of mutual interest, it will be the second phase of a long-range study of medical professional liability. The first phase polled some 7,500 physicians on their experiences in the area of malpractice. Both studies illustrate the increasingly close relationship of law and medicine (see Medicine at Work, THE JOURNAL, Dec. 15, 1956).

Questions will be in the areas of interprofessional relations, medical professional liability, and expert medical testimony. Realizing that attorneys' professional contacts with physicians vary widely, the questionnaire will also include a section to determine the individual experience that lawyers have had with doctors in their work.

Experiences and common goals relating to medicine and law led to the formation, in 1957, of a joint national medicolegal committee composed of representatives from both the A. M. A. and the American Bar Association. That committee drafted a National Interprofessional Code for Physicians and Attorneys, a guide for relationships between the two professions in legal procedures.

The Code was adopted by both the A. M. A. and the A. B. A. at their annual meetings this year. Calling for implementation at local levels (see Organization Section, THE JOURNAL, Aug. 23, 1958), the Code lays down suggested procedures in such areas as subpoenas, pretrial medical reports, court appearances, fees, and complaints.

Research and Specialism Will Highlight Education Congress

> Nothing out of its place is good and nothing in its place is bad. –Walt Whitman
>
> The origin of all science is in the desire to know causes; and the origin of all false science and imposture is in the desire to accept false causes rather than none; or, which is the same thing, in the unwillingness to acknowledge our own ignorance. –William Hazlitt

Those two quotations–the first signifying specialization and the second research–have been cited as keynotes for the 55th Annual Congress on Medical Education and Licensure when it convenes at the Palmer House in Chicago next Feb. 7 through 10. The Congress is sponsored by the A. M. A. Council on Medical Education and Hospitals in cooperation with the Association of American Medical Colleges, the Advisory Board for Medical Specialties, and the Federation of State Medical Boards of the United States. In carrying the themes of "Specialization in Medicine" and "the Role of Research in the Education of all Physicians," presentations and workshop sessions will explore such topics as:

–Specialism in relation to modern society, medicine, the pursuit of excellence, and the various phases of graduate medical education.

–General educational values inherent in the experimental method.

–The role of research in educational objectives of clinical and basic medical sciences and in graduate medical education.

–Research orientation relating to teachers and practitioners of medicine.

The Annual Congress last February attracted more than 1,000 medical educators and others in a program which highlighted the theme of medical education challenges and future needs. A detailed program for the coming Congress will appear in a future issue of THE JOURNAL.

There's That Word Again–

The word is serendipity–finding something valuable without deliberately looking for it–and on Jan. 18 physicians are scheduled to meet with scientists from other disciplines to discuss the imposing influence of "happy accident" phenomena. The "Bahamas Serendipity Session" at Nassau, believed to be the first of its kind, was arranged by Dr. B. L. Frank of Montreal. He says it was suggested by data reported in a Medicine at Work article in THE JOURNAL last Dec. 21. At last report, the program still was being compiled. Notices were sent to researchers in such fields as cybernetics, pharmacology, biophysics, bacteriology, and hydraulics.

"IMMUNE" OR "NO TAKE" REACTION IN SMALLPOX VACCINATION

DURING the American occupation of Japan at the end of World War II, and during the Korean conflict, some of our American military personnel contracted smallpox.[1] The unique situation was that these servicemen had been vaccinated against the disease and possessed records showing "successful" vaccination.

Epidemiologic investigations revealed that many of these so-called vaccinated soldiers' records showed "immune reaction," "no reading," "no reaction," or "no take." The term "immune" reaction should never be considered as evidence of a successful vaccination. While the phrase is used by some physicians when they see no physical signs at the site of inoculation, a negative reaction is more likely the result of improper preparation of the site of vaccination, a vaccine that has lost its potency (because of being outdated or more probably due to improper storage), or faulty technique in the actual vaccine process. The best clinical evidence seems to indicate that, even after a recent vaccination, revaccination if properly administered with potent vaccine will cause a demonstrable lesion at the vaccination site.

The "early" or "immediate" reaction develops in virtually all persons who have ever had a primary vaccinia take and is an allergic reaction to the vaccinia antigen and not related to the infectivity of the vaccine applied. In partially immune or susceptible individuals who have had a prior vaccination, such an allergic reaction to revaccination with potent live virus then subsequently proceeds to a vaccinoid reaction. Heat-inactivated smallpox vaccine can produce, in revaccinated persons, reactions that are morphologically indistinguishable from the so-called accelerated reactions after insertion of potent vaccine. Reactions have been observed to range from a simple papule to one in which the papule is replaced by vesiculation and pustulation, surrounded by a zone of erythema.[2]

If kept consistently below the freezing point, vaccine lymph may be expected to maintain its potency unimpaired for at least six months. If the lymph is stored below 50 F (10 C) it should maintain its potency for at least 14 days. If, however, the lymph is kept at ordinary room temperature its potency cannot be assured for more than seven days. Vaccine lymph should be stored in the dark and exposure to any source of heat should be avoided. Dried smallpox vaccine should retain its potency for at least six months without refrigeration in temperate climates, or for at least one month at tropical temperatures. When opened, the vaccine should be used at once; any surplus should be discarded and not kept for subsequent use unless it can be kept in a refrigerator at a temperature below 10 C when the potency may be maintained for a week.[3]

Jenner himself recognized the immediate type of reaction and it has even been proposed that this immediate reaction be called the Jenner reaction.[4] This particular reaction is found in all persons who have an active immunity from a previous case of smallpox, a vaccinia, or a vaccinoid reaction. The reaction comes on about 12 hours after vaccination and it lasts for 48 to 72 hours. It consists of a macule or a papule—rarely a vesicle. In those highly allergic individuals in whom a vesicle occurs as an allergic reaction, its early appearance distinguishes it from a vaccinoid response. There is slight induration around the vaccination site caused by the inflammatory reaction of the body destroying the cowpox virus. If one rolls the vaccination site under the finger one gets a feeling of possibly a small pea being in the skin.

Vaccine failures in primary immunization of very young infants have been shown to be due to interference by placentally transmitted maternal antibodies. Repeat vaccination at the age of 8 or 10 months is indicated. Repeated failures in revaccination should lead to attempts at another site, such as the opposite arm, away from the area of the previous scar. When protection is imperative, revaccination on the flexor surface of the forearm usually will result in a vaccinoid reaction in almost anyone.

Revaccinations should be inspected at three days and again at seven days. Actual evidence of immunity cannot be determined unless the site of vaccination is reexamined.

ORGANIZATION SECTION

REVISION OF CATEGORIES IN A. M. A. DIRECTORY

In the 1958 American Medical Directory there appears for the first time an attempt to delineate the type of practice. Categories are provided for "General Practice," "Full-time Specialists," "Part-time Specialists," etc., through 12 categories.

Confusion has been caused by the category referred to on page 9 of the Directory as "Full-time Hospital Staff—T. O. P. 5 Paid house officers who assist in conducting the professional work of the hospital, directly relating to the care and management of patients." In several respects, this wording is unfortunate. Many physicians who should have been classified as "full-time specialists" or "full-time medical school" or under some other classification, have been listed under T. O. P. 5.

A revision has been sent to all the owners of the 1958 Directory, which substitutes the following paragraph for the present T. O. P. 5:

"FULL-TIME STAFF IN HOSPITALS—T. O. P. 5. Physicians full-time in hospitals, other than interns and residents; includes many physicians who also could be classified under other T. O. P. categories such as full-time specialists, medical school faculty personnel, research, etc."

SECTION MEETINGS, ATLANTIC CITY, JUNE 8-12, 1959

The various sections of the Scientific Assembly that met in the morning at the San Francisco meeting will meet in the afternoon at Atlantic City, and vice versa, except where joint meetings are held between two or more sections. In such instances an afternoon section may meet jointly with other sections in the morning or a morning section may meet in the afternoon. The schedule follows:

Morning
Wednesday, Thursday, Friday
June 10-12

Anesthesiology
Dermatology
Gastroenterology and Proctology

COUNCIL ON INDUSTRIAL HEALTH

A GUIDE FOR MEDICAL SERVICES FOR CONSTRUCTION PROJECTS

This guide has been prepared by the ad hoc *Committee on Medical Services for Construction Projects of the Council on Industrial Health, American Medical Association, the members of which are Drs. Irving R. Tabershaw, New York, and Joseph A. Quigley, Cincinnati.*

B. DIXON HOLLAND, M.D., *Secretary.*

The official policy statement of the American Medical Association entitled "Scope, Objectives, and Functions of Occupational Health Programs" and the Council on Industrial Health publication entitled "Guiding Principles of Medical Examinations in Industry" were developed *primarily* to guide the establishment and operation of occupational health services in "ordinary," static employment situations. These statements offer considerable help in the establishment and operation of occupational health services for construction projects and are recommended for such use insofar as practicable. Construction projects, however, differ sufficiently from ordinary industrial operations and pose sufficiently different occupational health problems as to require an additional special occupational health guide. This statement is intended to serve as such a guide.

The Need for Medical Services for Construction Projects

Many serious personal injuries occur on construction projects. Aside from the humane consideration of providing the best in medical care, the scope of medical services available may affect considerably the total cost of the project. As indicated by the manual rates for workmen's compensation insurance, insurance losses in the construction industry are among the highest. In concrete construction, for example, the rate in different states varies from $2 to $10 per hundred dollars of payroll, and the rate for structural steel erection varies from $5 to $25 per hundred dollars of payroll (according to Liberty Mutual Insurance Company, New York). When it is considered that approximately half of the monies expended on any project is for wages, it can be seen that insurance losses may appreciably affect the total cost. Generally, at least 2% to 2½% of the total cost of construction is for workmen's compensation premium, e. g., for a 10 million dollar project, the premium would vary between $200,000 and $250,000. Since premiums vary according to the contractor's previous experience, some with poorer records are charged as much as two to three times the normal manual rate.

In addition to the medical and indemnity losses, there are the intangible factors, such as loss of time in travel to physicians' offices and interference with construction schedules. Accident prevention is the basic approach to the control of these losses, and the establishment of a competent medical service not only assists in the prevention of accidents but can minimize their ultimate ill-effects in terms of the residual impairment of the injured worker and the monetary loss involved. Records of the medical department in accidental injury cases, if properly kept and utilized, can assist materially in the accident prevention program.

Furthermore, an efficient medical service favorably influences the workmen's compensation experience by reducing losses after the accident has occurred. This is accomplished in a number of ways: 1. The initial care of an injury is good, i. e., first aid is administered quickly and properly since facilities and trained personnel are immediately available. 2. Treatment on the premises may prevent serious complications, as minor injuries are more likely to be reported and treated if the worker is not subjected to lost time and inconvenience in travel. When the worker obtains good and prompt medical care, the period of disability is reduced to a minimum, with economic gain to both the worker and the employer. 3. Serious and complicated cases will be referred at an early date to a qualified specialist, with the elimination of the cost of an intermediate physician's services and the reduction of lost time and compensation.

Good placement examinations are strongly urged, and contracts which exclude them are to be discouraged. The state of health of crane operators and truck drivers, for example, concerns their fellow workers, and their examination for placement should be compulsory. It is not advisable to allow a man to attempt to do work which is inconsistent with his abilities. Opposition to the proper placement examinations seems to be presented only by those who either fear their misuse as a bar to employment or have a callous disregard for the rights and safety of their fellow workers.

In some states (for example, New York) the general contractor is held liable for conditions which he creates or permits to exist on his jobs. As a result, in a large number of instances, subrogation rights have been exercised by subcontractors or their carriers to recover under the general liability coverage of the general contractor. With a well-operated and accepted medical department it has been found that at the time the injured employee is first treated a complete story can be obtained, the site of the accident can be examined, witnesses secured, and the information developed so that the possibility of a liability-type of case is minimized.

An additional reason for providing medical service on construction projects is that they are likely to be located in isolated areas and may involve problems of medical care which are not ordinarily encountered in other industries. Good medical service is also of value from a public relations standpoint.

Basic Requirements and Guide to Their Fulfillment

The effectiveness of a medical program depends to a great extent on the advance planning and its coordination with the safety program. Experience has proved that efficient services are rarely developed after a construction project has started. The following points should be considered:

Number of Workers Employed.—The number of workers employed each month by shift and by craft should be estimated. Employment is likely to be low at the initiation of a project, rise to a peak for a varying period, and then gradually taper off. On many projects local craftsmen are not available in sufficient numbers and with the necessary skills. The contractor may in such instances have to provide on-site barracks. This involves problems in sanitation and medical care. The area from which the labor force is recruited should be determined, as it is not unusual for workers on construction projects to drive several hours to and from work. This complicates the problem of on-site follow-up of injury and off-site medical care. Although a large number of workers may be involved, there may be fewer cases needing medical attention at any one time because of dispersal and varying shifts.

Unusual Features of Project.—Unusual features of the construction project should be considered and dealt with. For example, road building operation may require the use of mobile medical equipment. The building of a bridge may involve special problems of transportation and location of medical facilities. Silicosis and caisson disease may be special occupational hazards. Excessive heat and noise also may be problems. The likelihood of the occurrence of snake bite, insect-borne diseases such as malaria, enteric diseases such as typhoid fever, and other water and food-borne diseases should be considered. Tetanus may be a problem. Climatic conditions may cause frostbite and also may damage roads enough to make hazardous the transportation of injured or ill workers. The availability of community facilities for use in catastrophe should be determined. If a disease such as influenza is likely to reach epidemic proportions in the area, and if local facilities to deal with this problem are inadequate, the company will, by default, have to use its own judgment as to immunizing its employees. The solution for such problems necessitates special preparations and special facilities.

In addition to the above considerations, the following requirements are basic and must be fulfilled.

Physician.—A qualified physician should be employed to direct all medical services at the job site. The location of hospitals and the type of services they are prepared to offer should be determined. To utilize the physician's full potential, it is advisable to engage him on a continuing basis. His functions are (*a*) supervising the medical department, (*b*) supervising the first-aid facilities and personnel, (*c*) supervising the treatment of all occupational injuries and illnesses, (*d*) advising management on all medical policies and problems, (*e*) supervising job sanitation, (*f*) assisting in the safety program, (*g*) conducting physical examinations of workers, and (*h*) promoting health education and applying principles of health maintenance. Additional responsibilities and duties occasionally may be necessary depending on local conditions. In isolated communities these may be extended to include the medical care of the families of workers.

Emergency Medical Services.—Medical staff and facilities required for the particular construction project should be provided. The following general guides are suggested: 1. When a small construction force (less than 300) is to be employed for a short period (not more than two months), individuals trained in first aid usually will be the only "medical" personnel necessary on the premises. A qualified first-aid attendant should be available for each shift, and adequate first-aid kits should be available. Workers should be instructed to report all injuries. The first-aid attendant should be under the direction of the responsible physician, and injured workmen should be sent to the physician's office or to the hospital after being given first aid.

2. When a somewhat larger construction force (300 or more) is employed for a longer period (two months or more) a professional nurse, registered in the state, should be in attendance full time in an adequate medical facility on the premises. In addition, the nurse should have some training in industrial nursing and first aid. A physician should be retained on a part-time basis to visit the premises at regular intervals, and while there carry out all treatments as indicated and practicable. The medical facility should have adequate equipment and supplies for outpatient treatment.

3. When a large construction force (more than 2,000) is employed, a full-time physician with appropriate nursing staff should be engaged. When more than one nurse is employed, one should be designated to supervise. A medical facility should be provided on the premises adequate to implement the medical program. Provisions should be made for short-term inpatient care. The facility should be located near the construction operations and have such utilities as hot and cold running water, sewage disposal, and electricity. If a plant is being constructed, and if it is to have eventually a complete medical facility, consideration should be given to the early completion of such facility so that it may be used during the construction phase.

Medical Records.—A confidential medical records system should be established to include (*a*) a daily log listing chronologically all patients visiting the medical facility for occupational and nonoccupational injuries and illnesses, (*b*) cumulative individual medical records, (*c*) adequate workmen's compensation records, and (*d*) periodic statistical analyses.

Insurance Coverage, and Compliance with State and Local Laws.—The type of insurance coverage and the nature of the services provided by the carrier, e. g., industrial hygiene, rehabilitative, should be determined. The physician should acquaint himself with the procedures that will facilitate the processing of claims. The number of subcontractors and the type of work each does and the type of insurance coverage each has should be ascertained. Applicable state and local requirements in regard to the provision of medical care under workmen's compensation should be ascertained and complied with.

Job Sanitation.—Special problems in sanitation exist on all construction sites. Provision must be made for safe and potable drinking water, sewage disposal, and sanitary eating facilities.

COUNCIL ON NATIONAL DEFENSE

RESULTS OF SURVEY OF PHYSICIANS SEPARATED FROM ACTIVE MILITARY SERVICE

This opinion survey of physicians separated from active military service has been conducted by the Council on National Defense since 1952. The questionnaire utilized in the survey is primarily designed to obtain pertinent data based on the physician's observations and opinions, while in the armed forces, concerning the utilization of physicians and the medical staffing conditions in the uniformed services.

Periodically, the results of this continuing survey are reported in The Journal. *The questionnaire also requests comments and suggestions as to ways to further improve the Medical Corps as well as ways and means whereby organized medicine can be of greater assistance to military physicians. Consequently, the results of the survey serve as a basis for recommendations and conferences with representatives of the military establishment.*

Frank W. Barton, *Secretary,*
Council on National Defense

This report covers the period from Jan. 1, 1957, to Dec. 31, 1957. During that period, the Council sent out 2,055 questionnaire forms and, of these, 1,167 completed ones were returned, representing a 56.8% response.

The age distribution of responding physicians in the Army, Navy, and Air Force is disclosed in table 1.

Number of Years Since Graduation

More than half of the physicians replying to the question on years since graduation were graduated from medical school in 1950 or subsequent to 1950; the second largest group graduated during the period 1945-1949. None failed to indicate the years of graduation from medical school. Table 2 discloses the complete tabulation.

Table 1.—*Age Distribution of Physicians by Five-Year Age Groups*

Age	Army	Navy	Air Force
25-29	73	115	275
30-34	119	116	225
35-39	78	33	52
40-44	29	12	14
45-49	13	1	3
50 and over	4	3	2
Total	316	280	571

Table 2.—*Number and Percentage Distribution of Physicians Graduated from Medical Schools in Selected Intervals*

Interval	No.	%
Before 1940	15	1.3
1940-1944	87	7.5
1945-1949	313	26.8
1950 and later	752	64.4
Total	1,167	100.0

Years of Residency Training

The largest group replying to the question on years of residency training had no residency training while the second largest group had but one year residency training at the time of entrance on active duty. A complete breakdown is given in table 3.

Occupation at Time of Entering Service

The largest group of physicians who served in the Army, Navy, and Air Force were in residency training at the time of entrance in military service.

Table 3.—*Percentage Distribution of Total Physicians by Years of Residency*

No. of Years	No.	%
None	408	35.0
1	258	22.1
2	154	13.2
3	182	15.6
4	110	9.4
5	40	3.4
6	15	1.3
Total	1,167	100.0

The second largest group in all three services were in specialty practice. Table 4 indicates the percentage distribution by services according to type of practice at time of entering military service. The summary report for the year 1956 reflected that the largest groups in the Army and Navy were engaged in general practice at time of entrance on active military duty, while the largest group in the Air Force was in internship.

Table 4.—*Percentage Distribution of Physicians According to Type of Practice at Time of Entering Military Service*

	Army, %	Navy, %	Air Force, %
Internship	5.7	11.8	11.4
Residency	33.2	45.4	45.7
General Practice	22.5	14.6	15.8
Specialty Practice	30.1	18.2	16.1
Other	8.5	10.0	11.0
Total	100.0	100.0	100.0

Number of Physicians Holding Board Certificate by Field of Specialization

Table 5 shows the detailed numbers, by specialty and branch of service, of physicians holding board certificates. Of the 209 physicians who have board certificates, 78 were in the Army, 42 were in the Navy, and 89 were in the Air Force. The specialties covered over 15 different fields, of which the largest were internal medicine (34) and surgery (34). The second largest was radiology, and the third largest was pediatrics. In the previous report for the year 1956 internal medicine was first followed by surgery and pediatrics. By branch of service, a total of 24.7% of those in the Army, 15.0% of those in the Navy, and 15.6% of those in the Air Force had board certificates.

TABLE 5.—*Number of Physicians Holding Board Certificates by Field of Specialization*

Field of Specialization	Army	Navy	Air Force
Pediatrics	7	4	11
Psychiatry and neurology	5	4	8
Orthopedic surgery	4	..	7
Dermatology and syphilology	2	..	2
Radiology	7	6	12
Urology	2	1	1
Obstetrics and gynecology	5	1	2
Internal medicine	13	7	14
Ophthalmology	4	3	7
Pathology	5	4	5
Otolaryngology	1	..	2
Surgery	15	7	12

Neurological surgery	3	..	..
Unspecified	2	1	1
Total	78	42	89

Government Medical Education Received

Of the 1,167 physicians responding, a total of 193 stated that they had received assistance from the government in their medical education. There were 974 who indicated they had received no government assistance. The largest single group receiving government assistance was under the Army Specialized Training Program. The next two largest groups were under the Navy V-12 Program and the GI Program.

TABLE 6.—*Percentage Distribution of Physicians by Type of Governmental Medical Education Received*

	Army, %	Navy, %	Air Force, %
Army Specialized Training Program	54.4	22.7	44.5
Navy V-12	14.7	43.2	12.4
GI Bill	11.8	13.6	18.5
ASTP and GI Bill	13.2	...	8.6
Navy V-12 and GI Bill	1.5	9.1	4.9
Other	4.4	11.4	11.1
Total	100.0	100.0	100.0

Table 6 shows the percentages by branch of service. Of the responding physicians, 78.5% of those who served in the Army, 84.3% of those in the Navy, and 85.8% of those in the Air Force received no government assistance.

Training Received While in Service

There were 600 of a total of 1,167 responding physicians who received military medical training while on active duty in the Army, Navy, and Air Force. The Medical Field Service School accounted for the largest number, with the School of Aviation Medicine the second largest group. Table 7 sets forth the numbers and percentage distribution of physicians by type of training received in each branch of service. The totals in this table exceed the total number of responding physicians because some physicians took more than one course.

TABLE 7.—*Number and Percentage Distribution of Physicians by Type of Governmental Medical Training Received*

	Army		Navy		Air Force	
Type of Training	No.	%	No.	%	No.	%
Basic course, medical field service school	283	85.0	9	3.1	93	15.9
Advanced courses, medical field service school	10	3.0	1	0.3	5	0.9
School of aviation medicine	6	1.8	28	9.6	168	28.8
Marine medical officers training	...	...	10	3.4	...	...
Marine field service training	...	...	8	2.7	...	...
Amphibious forces training school	1	0.3	15	5.1	...	...
Other schools	2	0.6	2	0.7	1	0.2
None of the above	31	9.3	220	75.1	316	54.2
Total	333	100.0	293	100.0	583	100.0

Physicians' Evaluation of Military Training

The majority of physicians filling out the questionnaire felt that all important features of military training had been satisfactorily covered. A small percentage indicated the training was unsatisfactory but gave no specific reasons. Others stated reasons why they considered their military training unsatisfactory. Table 8 shows, by branch of service, the percentages that were satisfied and unsatisfied and the percentage distribution of the causes of dissatisfaction.

Physicians' Evaluation of Assignment

The majority of responding physicians stated that their longest and next longest assignments were almost completely in line with their training and experience.

With respect to satisfaction with assignments, a greater proportion of the Air Force and Army physicians expressed satisfaction concerning their longest assignment than did the Navy physicians, while more in the latter group were satisfied with their next longest assignment than were the Army and Air Force physicians.

TABLE 8.—*Physicians' Evaluation of Military Training*

	Army, %	Navy, %	Air Force, %
Satisfactory	82.6	68.9	79.5
Unsatisfactory	17.4	31.1	20.5
Total	100.0	100.0	100.0
Unsatisfactory and insufficient training in			
Basic orientation and indoctrination	29.1	62.5	39.3
Military customs, administration, regulations, etc.	25.4	20.5	24.8
Military medicine and surgery	18.2	11.4	13.7
Miscellaneous	20.0	1.1	18.8
No answer	7.3	4.5	3.4
Total	100.0	100.0	100.0

However, a considerably greater proportion of Army physicians were very satisfied with their longest assignment than were Navy and Air Force physicians. A greater proportion of Army and Navy physicians were very satisfied with their next longest assignment than were Air Force physicians.

Tables 9 and 10 show the percentages by branch of service for physicians who responded to this question.

Types of Patients Treated

One of the questions was designed to determine the percentage of time devoted by physicians to military personnel, dependents of military personnel, and administrative duties, both at domestic and overseas stations. Table 11 sets forth the percentages for all branches of service.

TABLE 9.—*Relation of Assignments in the Service to Training and Experience*

Questions and Replies	Army, %	Navy, %	Air Force, %
Was longest assignment in line with training and experience?			
Almost completely	63.0	49.5	65.4
Partially, but satisfactorily	15.1	18.3	21.1
Partially, not satisfactorily	13.2	18.6	10.0
No, hardly at all	8.7	13.6	3.5
Total	100.0	100.0	100.0
Was next longest assignment in line with training and experience?			
Almost completely	52.3	56.8	51.0
Partially, but satisfactorily	14.7	18.9	27.4
Partially, not satisfactorily	13.2	9.5	10.6
No, hardly at all	19.8	14.8	11.0
Total	100.0	100.0	100.0

TABLE 10.—*Physicians' Satisfaction with Assignment*

Assignment and Response	Army, %	Navy, %	Air Force, %
Longest Assignment			
Very satisfied	52.1	35.7	44.6
Fairly satisfied	27.4	35.4	38.1
Dissatisfied	12.7	16.4	11.5
Very dissatisfied	7.8	12.5	5.8
Total	100.0	100.0	100.0
Next Longest Assignment			
Very satisfied	45.9	44.4	37.0
Fairly satisfied	27.6	34.5	38.3
Dissatisfied	14.8	12.3	12.8
Very dissatisfied	11.7	8.8	11.9
Total	100.0	100.0	100.0

Types of Nonmilitary Medical Care Provided

The question which was designed to determine the types of medical duties most frequently performed for nonmilitary persons elicited the information that in all three branches of the service outpatient care ranked first at domestic and overseas stations. In the Army, surgery ranked second at both domestic and overseas stations. In the Navy, pediatrics was second at domestic and overseas installations. General medical and hospital care was second for Air Force physicians both in the United States and at overseas bases. Table 12 sets forth the types of services rendered and with what frequency.

TABLE 11.—*Percentage of Time Spent in Treating Military Personnel, Dependents of Military Personnel, and Other Duties*

Persons Treated	75-100%	50-75%	About 50%	25-50%	Under 25%	No Response
Military personnel						
Domestic	15.6	10.4	15.7	12.9	20.1	25.3
Overseas	13.9	4.9	7.3	5.1	4.9	63.9
Dependents of military personnel						
Domestic	20.1	9.5	14.1	14.1	18.7	23.5
Overseas	5.1	2.2	5.8	6.4*	9.8	70.7
All other duties

Overseas	1.5	0.7	1.5	3.4	13.8	79.1*

* Forced to total 100%.

Medical Care of Dependents of Military Personnel Which Could Have Been Adequately Performed by Civilian Medical Personnel

With respect to service in the United States, the majority of responding physicians were of the opinion that all medical care of nonmilitary persons could have been adequately performed by civilian medical personnel. In the three branches of the service, 582 of 930 physicians, or 63%, so responded. However, in regard to overseas service only 100 of 393 physicians, or 25%, were of that opinion. In fact, 140 of 393 physicians, or nearly 36%, stated that none of the medical care of nonmilitary persons at overseas stations could have been adequately performed by civilian medical personnel. Table 13 shows the percentages of physicians in the Army, Navy, and Air Force and their opinion in regard to the feasibility of the treatment of dependents of military personnel by civilian medical personnel at both domestic and overseas bases.

TABLE 12.—*Type of Service Provided to Dependents of Military Personnel*

Type of Service	Army, %	Navy, %	Air Force, %
Domestic			
Outpatient care	36.6	39.1	33.0
Surgery	14.8	9.6	12.2

Physicians' Evaluation of Staffing Conditions

One of the questions was designed to obtain the opinion of physicians as to staffing conditions of nurses, enlisted medical personnel, physicians, dentists, and others in the two units where the physician served his longest and next longest assignments. With respect to the longest assignment, the tabulation of this multiple-answer question indicated that in the Army replies indicating overstaffing totaled 160, understaffing 339, and adequate staffing 690. In the Navy, overstaffing totaled 165, nderstaffing 239, and adequate staffing 615. The ir Force tabulation revealed 314 replies of overaffing, 749 of understaffing, and 1,157 of adquate affing.

The response to the question concerning the next ngest assignment revealed that in the Army overaffing totaled 78, understaffing 126, and adequate affing 429. In the Navy, the results were 84, 115, nd 407, respectively, while the Air Force tabulaon was 106, 205, and 510 respectively. Table 14 eflects, in detail, the percentages relative to overtaffing, understaffing, and adequate staffing conitions in the three military services for the hysicians' longest and next longest assignments.

Unnecessary or Wasted Aspects of Military Training

There were 334 physicians who responded affirmatively to the question, "Were there any aspects of your military training that were unnecessary or wasted?" Negative answers were received from 833 medical officers. With respect to the affirmative replies, the most frequently mentioned area of waste was the performance of nonmedical duties. Table 15 shows the responses to this question by branch of service.

Physicians' Suggestions for Making Military Service More Attractive to Medical Men

There were 1,051 physicians who offered suggestions for making military service more attractive for physicians. Only 110 physicians felt that nothing could be done to make military service more attractive to medical men.

In the 1956 survey the number one suggestion was a recommended improvement in the utilization of medical personnel while the 1957 survey reveals a recommended increase in pay as the most frequent suggestion for making military service more attractive to medical men. The 1956 number one suggestion as well as a recommendation of adequate family housing did not appear as one of the top 10 suggestions in the results of the 1957 survey. Table 16 sets forth the suggestions from physicians in the three branches of military service.

Suggestions for Improvement of Services Furnished by Medical Associations to Military Physicians

A total of 397 physicians, or 34%, offered suggestions in response to the question concerning the role of national and local medical associations in maintaining closer contact or rendering better service to their members who served as physicians in the armed forces. Some physicians offered more than one suggestion. The multiple suggestions are tabulated in table 17. The other 770 physicians who returned the questionnaire offered no suggestions.

Physicians Who Would Voluntarily Remain in Service

In response to the question relative to military service beyond the obligatory tour of duty, 675 physicians indicated they would not be willing to stay in military service for more than two years of service under any conditions except total war. There were 492 physicians who indicated they would serve an additional period under certain conditions. Some physicians listed more than one condition. Table 18 reflects the reasons or conditions under which an additional period of service would be acceptable.

Preferred Branch of Service for Practice of Medicine

In response to the question of preference if the physician were going to practice medicine in a federal government agency, 453 physicians stated a preference for the armed forces. A total of 436 physicians expressed a preference for other agencies of the federal government, 248 had no preference, and 30 did not answer. Of those who preferred the armed forces, the majority chose the branch of service in which they had served. Table 19 sets forth the preferences as to branch of service.

Distribution of Physicians by Rank at Time of Discharge

The majority of physicians in the Army and Ai Force held the rank of captain at the time of th release from active military duty, while those sep rated from the Navy held the equivalent rank lieutenant, senior grade. There were 1,102 phy cians who answered this question. The survey in cated that approximately 2% of those who ported were in the lowest rank, while 85% held rank of captain or lieutenant, senior grade. Th were approximately 13% with the rank of major lieutenant commander and higher. Table 20 in cates the number and percentages by rank wit the three services.

Reserve Status

Of the 1,167 physicians reporting, 193 indicat they retained their reserve commissions while 9 resigned their commissions. There were two wl did not respond. By services, the Army had retaining commissions and 247 resigning; the Na had 44 retaining and 236 resigning; and the Force had 81 retaining and 489 resigning th commissions. Table 21 reflects the percentages branch of service.

Length of Active Service as a Medical Officer

In the Army 308 responding physicians serv an average (median) of 23 months in the Unit States and 152 responding physicians served an average (median) of 21 months at overseas stations. There were 279 naval medical officers who had an average (median) of 24 months active duty in the United States and 108 naval medical officers had an average (median) of 12 months overseas. Responses from 545 physicians in the Air Force revealed an average (median) tour of duty of 24 months in the United States, and 194 physicians in the Air Force had an average (median) tour of duty of 22 months at overseas bases.

MEDICAL NEWS

CALIFORNIA

Dr. Freeman Comes to California.—Dr. Gustave Freeman, medical researcher, has joined the biological sciences department at Stanford Research Institute as program director of medical research. He will direct preclinical cancer research at the institute and clinical studies conducted with neighboring hospitals. Concurrently with his assignment, Dr. Freeman will conduct an advanced program on nucleic acids with Prof. George W. Beadle, recently named to share the 1958 Nobel prize in medicine, at California Institute of Technology. Dr. Freeman comes to Stanford Research Institute from the Cancer Chemotherapy National Service Center at Bethesda, Md., where he was head of the clinical pharmacology and therapeutics section. In addition, he was a consultant-in-biology for the Children's Hospital in Boston; a member of the Johns Hopkins Hospital medical staff; and an assistant professor of medicine, Johns Hopkins University School of Medicine, Baltimore.

COLORADO

State Medical Election.—The Colorado State Medical Society has installed the following officers: president, Dr. John Zarit, Denver; president-elect, Dr. John L. McDonald, Colorado Springs; vice-president, Dr. Robert P. Harvey, Denver; treasurer, Dr. William C. Service, Colorado Springs; and constitutional secretary, Dr. Harry C. Hughes, Denver.

DELAWARE

Centers for Retarded Children.—Delaware reportedly has opened the first state-supported day care center for severely mentally retarded children in the U. S. Only the most helpless of the mentally retarded are accepted for care—from 9 to 5 five days a week. The purpose is twofold: to try to train the children in the basic phases of self-care; to relieve their parents of the constant strain of taking care of them at home. This is the first of a series of centers to be set up throughout Delaware under the jurisdiction of Dr. Mesrop A. Tarumianz, state mental health director.

ILLINOIS

Request for Old Pictures of Autos.—The Illinois State Medical Society is preparing an exhibit centered around an *Illinois Medical Journal* article which told of the role of physicians in the development of the automobile in the U. S. at the turn of the century. To help illustrate this exhibit, the society will appreciate the loan of old photographs showing physicians at the wheels of cars of 1900-1910 vintage. Scenes showing difficulties on the road, or poor highway conditions, are especially desired. Enlargements will be made of these photographs and the originals returned undamaged. Photographs should be accompanied by a memo giving the name and town of the physician, whether living or deceased, and the make and year of the automobile. They should be sent to Mr. John A. Mirt, Illinois State Medical Society, 185 N. Wabash Ave., Chicago 1.

Chicago

New Department of Experimental Surgery.—Michael Reese Hospital and Medical Center has announced the appointment of Dr. William C. Shoemaker as head of its new department of experimental surgery which will begin operations Jan. 1, 1959. Dr. Shoemaker at present is an assistant in surgery at the Peter Bent Brigham Hospital, Boston, and a research fellow at Harvard Medical School. At Michael Reese he will continue his research on the metabolism of the liver in surgical conditions, and other work of the newly formed department will concern the role of the autonomic nervous system in various surgical problems and the reconstruction of intraperitoneal smooth muscle organs. Dr. Shoemaker, a native of Chicago, received his M.D. degree from the University of California, San Francisco, in 1946 and served 38 months with the U. S. Navy Medical Corps.

MAINE

Dr. Hill Receives Huddilston Medal.—Dr. Frederick T. Hill, Waterville, medical director of Thayer Hospital, was honored recently by the Maine Tuberculosis Association which awarded to him its Roselle W. Huddilston Medal "for distinguished service and outstanding contributions in the field of health to the people of the State of Maine." The Huddilston Medal established in Maine to honor health leaders and recognize their work, is named for Mrs. John Homer Huddilston of Orono, a volunteer health worker and leader in the state for more than 40 years. It is given "in recognition of contributions within the total field of health which is in keeping with the tuberculosis association's concept that it should be interested in all aspects of health improvement, for all are important and

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

they all contribute to tuberculosis control." The medal is not limited to physicians and is primarily awarded in recognition of services rendered beyond the call of a person's ordinarily defined responsibilities and duties. The medal was presented to Dr. Hill at the annual meeting of the Maine Tuberculosis Association by Dr. Thomas A. Foster, Portland, chairman of the Huddilston Medal Committee. A citation, describing Dr. Hill's accomplishments, listed service as president of the Maine Medical Association (1936-1937), the Maine Hospital Association (1944-1946), and the New England Hospital Assembly (1954).

MASSACHUSETTS

State General Practitioner of the Year.—The Executive Committee of the Massachusetts Medical Society has named Dr. Kathleyne S. Snow as the society's "General Practitioner of the Year" and its nomination for the A. M. A. national award. Dr. Snow is the first woman physician to receive the Massachusetts honor. After her graduation from Tufts College Medical School in 1923, Dr. Snow set up practice in Jamaica Plain, where she continues to practice. In presenting her nomination to the Executive Committee her fellow physicians of the Norfolk District stated, in part, "A credit not only to the women in medicine, but to the whole medical profession, Dr. Snow richly deserves the honor of being selected as the Massachusetts General Practitioner for 1958."

MICHIGAN

Lecture on Schizophrenia.—Dr. Marvin L. Adland, clinical director of Chestnut Lodge Sanitarium, Rockville, Md., will give a lecture on the treatment of schizophrenia at the Haven Sanitarium, Rochester, Mich., Dec. 13.

Dr. Krystal Receives Research Award.—The Michigan Society of Neurology and Psychiatry on Oct. 23 presented its research award to Dr. Henry Krystal, an associate member of the society. This award, consisting of a prize of $250 and an appropriate scroll, is presented annually "for meritorious original work in neuropsychiatry done by men in the first five years of training or experience." Dr. Krystal's paper was entitled "Physiological Treatment of Delirium Tremens," and has been accepted for publication in the *Journal of the American Psychiatric Association.*

MINNESOTA

Institute on Perinatal Casualties.—The University of Michigan School of Public Health and the University of Minnesota School of Public Health will jointly hold an "Institute on Perinatal Casualties" Dec. 8-12 in Minneapolis, financed by a grant from the U. S. Children's Bureau. The program will be a series of seminars and discussions. Faculty case finding, care, and follow-up; perinatal mortality studies; care of the premature infant; etc. For informati write Dr. Donald C. Smith, associate professor o maternal and child health, University of Michiga School of Public Health, Ann Arbor, Mich., o Dr. Helen M. Wallace, professor of maternal and child health, University of Minnesota School of Public Health, Minneapolis, Minn.

NEBRASKA

Select Committee on Research.—Dr. Charles M Wilhelmj, professor of physiology, has been named chairman of an all-University Committee on Research at Creighton University School of Medicine, Omaha. This committee was selected by the Academic Senate, composed of deans of the various schools and colleges under the chairmanship of the academic vice-president, the Rev. William F. Kelley, S.J. The newly-named group will act as a clearing house for research in the university and as university agent in general research grants. Further, the Committee on Research will encourage, advertise, initiate, and approve research in the several colleges. It will serve as liaison body with the Jesuit Research Council of America.

NEVADA

State Medical Election.—The following officers of the Nevada State Medical Association have been elected for 1958-1959: Dr. Roland W. Stahr, president; Dr. Ernest W. Mack, president-elect; Dr. William A. O'Brien, III, secretary-treasurer; Dr. Wesley W. Hall, A. M. A. Delegate; and Dr. Earl N. Hillstrom, A. M. A. Alternate Delegate, all of Reno.

NEW MEXICO

Dr. Lovelace to Speak at Holloman.—Dr. William R. Lovelace, II, will fly to Holloman Air Force Base as guest of honor for the Dec. 9 dinner meeting of the Holloman Section, American Rocket Society. Dr. Lovelace will explore various aspects of human factor research related to the hazard encountered by "Man in Space." Formerly chief o the Aero Medical Laboratory at Wright Air Development Center, Dr. Lovelace is now an official o the Lovelace Foundation. He has also served a chairman of the Aeromedical Panel of the USA Scientific Advisory Board and is now a member o the NATO Advisory Group for Aeronautical Research and Development (AGARD) under D Theodore von Karman.

NEW YORK

Lectures on Psychiatric Care.—A series of six lectures on practical aspects of psychiatric care in th community is being presented to North Country area physicians by Drs. Warren A. Mann and David B. Robinson, both assistant professors of psychiatry. The lectures, which started Oct. 28, will end Dec. 11 and are being held at Mercy Hospital, Watertown. Presented at the request of the Jefferson

County Academy of General Practice and designed to provide information helpful in psychiatric problems encountered in the general practice of medicine, the lectures are concerned with development of psychosocial problems, diagnosis, immediate treatment, legal considerations, and community resources and responsibilities that may be developed. Sponsoring the lectures are the New York State Medical Society, the Jefferson County Medical Society, the Jefferson County Mental Health Association, and the academies of general practice of the four participating counties. Sessions are held from 7:30 to 9:30 p. m.

New York City

Annual Wechsler Lecture.—The annual Israel S. Wechsler Lecture will be given Dec. 12, 8:30 p. m., in the Blumenthal Auditorium of the Mount Sinai Hospital. Charles M. Pomerat, Ph.D., professor of cytology, University of Texas, Galveston, will speak on "Recent Advances in the Study of Living Nerve Tissue."

Centennial Exhibit for Dr. Koplik.—In celebration of the 100th anniversary of the birth of Dr. Henry Koplik (1858-1927) "one of New York City's pre-eminent physicians," an exhibition bearing upon the life and achievements of Dr. Koplik will be placed on view in The New York Academy of Medicine. Dr. Koplik was a specialist in the diseases of children, was an eminent exponent of preventive medicine, and is most widely known as the discoverer of the "Koplik's Spots." He was the founder of the first "Milk Depot," making milk available to the poor and the underprivileged free or at a minimum cost. Dr. Koplik served as medical director of the Good Samaritan Dispensary, and was one of the founders of the American Pediatric Society and at one time was its president. The exhibit at The New York Academy of Medicine, organized by Dr. Murray H. Bass and Dr. Jerome L. Kohn, will be on view at The New York Academy of Medicine, first floor lobby, until the end of December. The public is invited. Admission is free.

OHIO

Annual Meeting on Internal Medicine.—The annual meeting of the Ohio Society of Internal Medicine will be held Jan. 21, 8 p. m., at the Netherland Hilton Hotel, Cincinnati. The presiding officers will be Dr. Arnoldus Goudsmit, Youngstown, president; Dr. George J. Hamwi, Columbus, vice-president; and Dr. Leonard P. Caccamo, Youngstown, secretary-treasurer. The meeting will be devoted to a review of the progress made by the society in the interest of patient care requiring the specialty of internal medicine in the State of Ohio during the year 1958. Dr. A. Carlton Ernstene, governor of the college for Ohio, has invited the Ohio Society of Internal Medicine to take part in the program of the Ohio Regional Meeting of the American College of Physicians to be held Jan. 22 at the Veterans Administration Hospital in Cincinnati. The program will include the presentation of a panel dealing with "Status of the Internist in Medical Care Plans," moderated by Dr. Hamwi, head, division of endocrinology and metabolism, Ohio State University College of Medicine. The panel will consist of four members: Dr. William B. Walsh, chairman, Legislative Committee of the American Society of Internal Medicine, Washington, D. C.; Dr. John J. Grady, chairman, Committee on Insurance Plans, Cleveland Society of Internal Medicine, Cleveland; Mr. Charles H. Coghlan, executive vice-president, Ohio Medical Indemnity, Inc., Columbus; Dr. Paul I. Robinson, coordinator of medical relations, Metropolitan Life Insurance Company, representing the Health Insurance Council, New York City.

OREGON

Grant for Research Building.—A grant of $1,297,955 from the National Advisory Council of the National Institutes of Health for construction of the University of Oregon Medical School's proposed Medical Research Building was approved in late September, paving the way for a request by the Board of Higher Education for matching funds from the 1959 Oregon State Legislature. Preliminary plans for the research structure were approved by the Higher Education Board in June. The building will be rectangular, 57 by 182 feet. It will be nine stories high including two stories below ground, with a total floor area of about 106,902 square feet, and designed so that five additional stories can be added at some future date. The building will be located north of the Medical Science Building. It will be constructed of reinforced concrete with exterior finish to be of glass and panel construction. Interconnection between the new and existing facilities will be provided. Provisions are incorporated in the plans for storage and processing of radioisotopic materials and for radioactive materials laboratories. Animal quarters are planned in the two sub-grade levels.

PENNSYLVANIA

Philadelphia

Symposium on Hypertension.—The Hahnemann Medical College and Hospital will present a Symposium on Hypertension at the Town Hall, Philadelphia, Dec. 8-12, under the following section headings: Pathology and Clinical Aspects of Hypertension, Basic Concepts of the Etiology of Hypertension, Pharmacology of Hypertension and Use of Sympathetic Blocking Agents, and The Role of Salt and Diuretics in the Therapy of Hypertension. The latter part of the symposium concerns medical and surgical treatment. On the third and fourth day, the clinical pharmacodynamics and therapeutic use of drugs will be considered. Panel discussions scheduled for Dec. 12 will have the following titles and moderators:

Development of an Effective Therapeutic Program, Dr. John H. Moyer.
Effect of Therapy on Prognosis in Patients with Hypertension, Dr. Charles C. Wolferth Sr.
Surgical Approach to Essential Hypertension, Dr. John M. Howard.

Participants in the symposium include Dr. William D. M. Paton, professor of pharmacology, Royal College of Surgeons of England, London, who will present "The Rationality or Irrationality of Ganglionic Blocking Agents in Hypertension," and Dr. Mordochai Toor, head, third medical department and cardiopulmonary laboratory, Beilinson Hospital, Kupat-Holim, Petah-Tikva, Israel, who will speak on "The Effect of Increased Intrapulmonary, Intracardiac, and Intra-arterial Blood Pressure on Sodium Excretion."

University Center for Radiology.—The William H. Donner Center for Radiology of the University of Pennsylvania received a $150,000 endowment gift from The Donner Foundation when the one-million-dollar center was dedicated earlier this year. The gift for endowment was in addition to the foundation's earlier contribution of $600,000 toward construction of the center. The foundation also donated a 2-million-volt x-ray machine. The center, located adjacent to the Hospital of the University of Pennsylvania, was named for William H. Donner, Pennsylvania industrialist and philanthropist, in recognition of his long interest in radiological diagnosis and treatment. It was constructed at a cost of $847,000, plus $184,000 for equipment. The Fels Fund contributed $25,000 for a radiobiology research program, and the U. S. Public Health Service provided more than $284,000 in grants for equipment and construction. The center consists of three floors, providing 16,000 square feet of floor space, and is connected with the present department of radiology at the hospital. The basement level contains electronic and precision machine shops and an auditorium seating 68 persons. Patient care is centered on the main floor, and the second floor will serve as the experimental and service floor.

The William H. Donner Center for Radiology of the University of Pennsylvania, Philadelphia.

UTAH

University of Utah Medical Center Planned.—In 1957, the State Legislature authorized construction of a unified medical center on the University of Utah campus, Salt Lake City, and made an initial appropriation of funds for planning and construction. This new plant will bring together under one roof the many activities of the College of Medicine and Nursing now housed in widely scattered temporary buildings. Work has already gone into preliminary plans for the new structure, including individual and team visits to other medical centers of the country, visits to Salt Lake City of various expert consultants, full-time services of a "space analyst" experienced in medical center planning, etc. Faculty committees and architects are now working jointly on "preliminaries." At an estimated cost of 10 million dollars for construction and 2 or 3 million for utilities, landscaping and equipment, this reportedly will be one of the smallest and least costly of university medical centers in the U. S. About two-thirds of the funds needed for the project are in hand or in prospect. A public campaign is now being initiated to raise the remainder.

WEST VIRGINIA

General Practice Meeting in Charleston.—The 10th anniversary of the West Virginia Chapter of the American Academy of General Practice will be observed at a meeting at the Daniel Boone Hotel in Charleston Dec. 7 with a special scientific assembly. A film, "Building For Tomorrow," will be shown during the period from 9:30 to 10 a. m., after which the following program will be presented, with a luncheon at noon:

10 a.m.—Pre- and Post-Partum Gynecological Problems, Dr. John H. Holzaepfel, assistant professor, department of obstetrics and gynecology, Ohio State University College of Medicine, Columbus.
11 a.m.—An Appraisal of Present Therapy for Peptic Ulcer, Dr. Charles M. Caravati, associate professor of clinical medicine, Medical College of Virginia, Richmond.
2 p.m.—Acute Chest Surgery, Hiatal Hernia, and Open Heart Surgery, Dr. Donald B. Effler, department of chest surgery, Cleveland Clinic, Cleveland.
3 p.m.—Respiratory Infections—A General Review of Diagnosis and Modern Treatment, Dr. William Curtis Adams, assistant professor of child health, department of pediatrics, University of Louisville School of Medicine, Kentucky.

Members of the American Academy of General Practice will be granted 4½ hours category one credit for attendance at the meeting. There will be no registration fee.

WISCONSIN

Academy Meeting in Milwaukee.—On Dec. 16-20 the Milwaukee Academy of Medicine will present a series of conferences, clinics, and ward rounds to be directed by Dr. Arnold S. Relman, associate professor of medicine, Boston University School of Medicine, and physician in charge of the Renal and Metabolic Clinic at the Robert D. Evans Memorial Hospital, Boston, concerning "Electrolyte Problems and Renal Disease" and also fluid and electrolyte problems as encountered in other fields of medicine. All sessions are open to interested physicians without registration fee.

Dec. 16—University Club of Milwaukee, Cocktails and Dinner, 6:00 p.m., *scientific session,* 8:00 p.m.
Clinics and Rounds: 9:00 a.m. to 12 Noon.
Dec. 17—Milwaukee County General Hospital.
Dec. 18—Veterans Administration Hospital, Wood.
Dec. 19—Milwaukee Children's Hospital.
Dec. 20—Milwaukee County General Hospital.

For information write the Milwaukee Academy of Medicine, 561 N. 15th St., Milwaukee.

GENERAL

Retarded Child Programs Expand.—The Oct. 11 *Science News Letter* reports that efforts to understand the causes of and care for the mentally retarded child have mushroomed from four state programs three years ago to 44 such programs today. In 1955, four states were pioneering in the mental retardation problem. These states were receiving only $141,000 in special project money advanced by the Children's Bureau of the U. S. Department of Health, Education and Welfare, Mrs. Katherine B. Oettinger, chief of the bureau, said. In 1956, the federal government ear-marked one million dollars annually for state mental retardation projects. A major goal of the fund was to close the gap between early detection and treatment of mental retardation in preschool children. Several of the state programs that are supported by federal funds are training future physicians in the diagnosis and treatment of various forms of mental retardation. Some of the state projects are located in university medical centers. Some, as in Minnesota, Maine, Georgia, and Idaho, are concentrated in rural counties in an effort to determine both the need for services and the available resources that can be developed. In Florida, Colorado, Alaska, and Massachusetts the emphasis is on how to integrate mental retardation programs into the services of local health departments. Most of the children seen in these projects are of preschool age. Determination of the nature and degree of mental retardation, and the causes, is the first point of assistance. Consideration is given to physical conditions that, if improved, would lessen the handicap. The family situation affecting the child's condition is carefully studied, and resources in the community to aid the child are sifted.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories and possessions in the weeks ended as indicated:

Poliomyelitis Morbidity Trends.—According to the Poliomyelitis Surveillance Report of the Communicable Disease Center, Atlanta, Ga., for Oct. 31, during the 43rd week ending Oct. 25, 253 new cases (155 paralytic) were reported to the National Office of Vital Statistics. This represents a decrease in the total, but an increase in the paralytic cases. The previous week 289 cases were reported of which 140 were paralytic. Late seasonal rises in polio are not uncommon, the report stated, but the persistence of cases at this level, this long after the peak during the 38th week, is unusual. For the first time this year, paralytic cases exceeded the number for the corresponding week in 1956. During the 43rd week in 1956, 320 cases with 140 paralytic were reported. Aside from the concentration of cases in Michigan (total 57—paralytic 20), paralytic cases are distributed widely throughout the nation.

CANADA

Research Institute in Saskatoon.—The Saskatchewan Cancer and Medical Research Institute was formally opened May 10. The Institute has been built on the campus of the University of Saskatchewan College of Medicine, Saskatoon, through funds supplied by the Saskatchewan Division of the Canadian Cancer Society and the Government of Saskatchewan. It is connected by tunnel with the Medical Building and the University Hospital and will provide housing for the Saskatchewan Research Unit of the National Cancer Institute of Canada as well as a radiation physics group and a tissue culture suite occupied by the department of anatomy and bacteriology of the University of Saskatchewan. The lower floor will provide laboratory space for the clinical departments of anaesthesia, medicine, pediatrics, neurosurgery, and surgery.

CORRECTION

Psychoanalysis Meeting Dec. 6-7.—In the Nov. 15 issue of The Journal, p. 1562, the mid-winter meeting of the Academy of Psychoanalysis was reported to have been held Nov. 6-7. Dr. Jules H. Masserman, past-president, who was given as president, has written that the academy "will hold its midwinter meeting at the Roosevelt Hotel, New York City, Dec. 6-7, under the presidency of Dr. William V. Silverberg, of New York."

EXAMINATIONS AND LICENSURE

MEDICAL SPECIALTY BOARDS

American Board of Anesthesiology: *Oral.* Phoenix, April 5-10. All applications already on file. Sec., Dr. Forrest E. Leffingwell, 217 Farmington Ave., Hartford 5, Conn.

American Board of Dermatology: *Written.* Several Cities, Oct. 5. *Oral.* Oklahoma City, Jan. 15-18, 1960. Sec., Dr. Beatrice M. Kesten, One Haven Ave., New York 32.

American Board of Internal Medicine: *1959 Schedule—Written,* Oct. 19. Final date for filing application is May 1. *Oral.* For candidates in the South and Southwest, New Orleans, Feb. 3-6. Final date for filing application is Jan. 1. *Oral.* For candidates in the Midwest. Chicago, April 15-18. Final date for filing application is Jan. 1. *Oral.* For candidates on the West Coast. Final date for filing application is March 1. *Oral.* For candidates on the East Coast, Nov. 6-7, 9-10. Final date for filing application is March 1. *Examination in the Subspecialties. Gastroenterology.* Philadelphia, April 17-18. Final date for filing application is Feb. 1. Sec.-Treas., Dr. William A. Werrell, One West Main St., Madison 3, Wis.

American Board of Neurological Surgery: Examination given twice annually, in the spring and fall. In order to be eligible a candidate must have his application filed at least six months before the examination time. Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, St. Louis 10.

American Board of Obstetrics and Gynecology: *Part I.* Various parts of the United States and Canada, January 16. Candidates notified of their eligibility to participate in Part I must submit their case abstracts within thirty days of notification of eligibility. No candidate may take the written examination unless the case abstracts have been received in the office of the Secretary. *Oral and Clinical.* Chicago, May 8-19. Formal notice of the exact time of each candidate's examination will be sent him in advance of the examination dates. Candidates who participated in the Part I examinations will be notified of their eligibility for the Part II examinations as soon as possible. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: *Written,* qualifying test (Part I), Various Cities, Jan. 26. *Oral.* Philadelphia, June 3-6. Sec., Dr. Merrill J. King, 22 White St., Rockland, Maine.

American Board of Orthopaedic Surgery: *Part I.* Washington, D. C., Denver, Colorado and Rochester, Minn., Mar. 26-27. Deadline for filing application was Nov. 30. *Part II.* Chicago, Jan. 21-23, 1959. Deadline for receipt of applications was Aug. 15. Sec., Dr. Sam W. Banks, 116 South Michigan Avenue, Chicago 3.

American Board of Otolaryngology: *Oral.* Chicago, Oct. 5-9. Final date for filing application is February. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

American Board of Physical Medicine and Rehabilitation: *Written, Part I,* and *Oral, Part II.* Philadelphia, June 12-13. Final date for filing application is February 15. Sec., Dr. Earl C. Elkins, 200 First St., S. W., Rochester, Minn.

American Board of Plastic Surgery: *Oral and Written.* Boston, May 9-11. Final date for submitting case reports is Jan. 1. Corresponding Secretary, Miss Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8, Mo.

American Board of Preventive Medicine: *Written. Public Health.* Regional, Apr. 9-11. *Occupational Medicine.* Chicago, Apr. 17-19. *Aviation Medicine.* Los Angeles, Apr. 24-26. Final date for filing application for all three examinations is Jan. 15. Sec., Dr. Tom F. Whayne, 3438 Walnut St., Philadelphia 4.

American Board of Proctology: *Oral and Written.* Philadelphia, September. Final date for filing application is March. Sec., Dr. Stuart T. Ross, 520 Franklin Ave., Garden City, N. Y.

American Board of Psychiatry and Neurology: New York City, Dec. 15-16; New Orleans, Mar. 16-17. Training credit for full time psychiatric and/or neurologic assignment in unapproved military programs or services between the dates of Jan. 1, 1950 and Jan. 1, 1954 will be terminated on Jan. 1, 1959. Sec., Dr. David A. Boyd, 102-110 Second Ave. S. W., Rochester, Minn.

American Board of Radiology: *Special Examination.* Cincinnati, Mar. 16-19, 1959. Final date for filing application was Nov. 1. Candidates completing training June 30, 1959 are not eligible for the Spring 1959 examinations. Sec., Dr. H. Dabney Kerr, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery: *Part II.* New York City, Dec. 15-16; Houston, Tex., Jan. 12-13; New Haven, Conn., Feb. 9-10; Durham, No. Car., March 9-10; San Francisco, April 13-14; Indianapolis, May 11-12; Columbus, Ohio, May 14-15. Sec., Dr. John B. Flick, 1617 Pennsylvania Blvd., Philadelphia 3.

Board of Thoracic Surgery: *Oral.* Los Angeles, April. Final date for filing application is Dec. 1. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2.

American Board of Urology: The oral will be given in Chicago in February 1959. Sec., Dr. William Niles Wishard, Jr., 30 Westwood Road, Minneapolis 26.

GOVERNMENT SERVICES

AIR FORCE

Personal.—Col. John E. Pickering, chief, department of radiobiology, has been named director of medical research at the U. S. School of Aviation Medicine, San Antonio, Texas. Colonel Pickering, formerly director of the Health Physics Society of America, is the author of textbooks entitled "Student Handbook of Weather" and "Air Navigation," and of many scientific papers.

ARMY

Personal.—Col. Floyd L. Wergeland, executive director, Office for Dependents' Medical Care, was promoted to the rank of brigadier general on Oct. 8. Formerly, General Wergeland was chief of the personnel division in the surgeon general's office.

Col. John L. Crawford, commanding officer, 9th Hospital Center, Landstuhl, Germany, was also recently promoted to the rank of brigadier general.

NAVY

Surgeon General Receives Peru Award.—Surgeon General Rear Adm. Bartholomew Hogan has been awarded the Peruvian Cross of Merit by the president of Peru and the Peruvian Navy. The decoration was presented through Rear Adm. Luis Edgardo Llosa, Naval Attaché, Embassy of Peru, Washington, D. C., Oct. 8, in connection with the celebration of Peruvian Navy Day. This award was made in recognition of the assistance the U. S. Navy Medical Department has given the Peruvian naval medical department.

VETERANS ADMINISTRATION

Wheel Chair Homes.—More than 5,400 seriously disabled veterans have received federal grants totaling more than 51 million dollars for "wheel chair homes," the VA has announced. As of Sept. 30, some 7,091 veterans who, because of service-connected disabilities, cannot get about without the aid of wheel chairs, crutches, braces, or the like, had established their eligibility for these special grants. Of these, 5,415 already have received the grants and either have moved into their homes or are in the process of having them built. The remainder have not yet put their plans into effect. The VA defrays 50% of the cost of "wheel chair homes" for eligible veterans up to a maximum of $10,000 under grants which were first authorized in 1948. The average grant is $9,468.

Research Program Expanded.—About 15 million dollars is available for VA medical research during the present fiscal year, and that is 5 million more than was available last year. The major new emphasis in the agency's research will be on studies of mental and physical deterioration associated with aging, says Dr. Martin M. Cummings, director of the *VA* research service in *Washington, D. C.*

PUBLIC HEALTH SERVICE

Nobel Prize Winners.—The three scientists who were awarded the 1958 Nobel Prize in Medicine and Physiology have been closely associated for many years with research supported by the National Institutes of Health (NIH). The NIH programs support scientific medical research of high caliber through grants for research studies, research training, and research facilities construction. Nearly half of America's medical research is supported through these grants, which will number some 7,000 this year. The awards are made on the recommendation of over 700 nonfederal advisers who review applications for grants as members of study sections and advisory councils.

Dr. Joshua Lederberg of the University of Wisconsin has been receiving an NIH grant for 10 years. He is a member of the newly formed Genetics Study Section of NIH, having been a member of the Morphology Study Section from 1949 to 1953. His current grant is from the National Cancer Institute. Dr. Edward Tatum of the Rockefeller Institute for Medical Research is a member of the Division of General Medical Sciences Genetics Training Committee and has received grant support from NIH since 1951. His current grant is from the National Cancer Institute. Dr. George Beadle, California Institute of Technology, was the first scientist to deliver a Dyer Lecture at NIH and is now receiving a National Heart Institute grant, working in experimental biology and genetics. His current project is expected to receive support until 1961.

Grants for Research in Metabolic Diseases.—Research grants and fellowships totaling $20,705,780 were awarded during September by the National Institutes of Health, at Bethesda, Md. Forty-seven per cent of the grant funds awarded during September are for support of research in arthritis and metabolic diseases. The grants were made to 337 institutions in 45 states, the District of Columbia, 2 territories, and 18 foreign countries. Research fellowships totaling $581,369 were awarded to 150 individuals for study in 93 institutions in 33 states, the District of Columbia, and 2 foreign countries.

Dr. Wright Receives Award.—Dr. Willard H. Wright, D.V.M., a Public Health Service consultant and former chief of the laboratory of Tropical Diseases of the National Institutes of Health was awarded the Walter Reed Medal by the American Society of Tropical Medicine and Hygiene. Research by Dr. Wright and co-workers resulted in improved control or treatment of such diseases as malaria, schistosomiasis, and filariasis. Advances were also made against trichinosis, toxoplasmosis, pinworm infection, and amebic dysentery.

DEATHS

Alderman, Mason Clarence, North Kansas City, Mo.; University Medical College of Kansas City, 1903; died Sept. 26, aged 87.

Andersen, Silas Carl Ⓜ Minneapolis; University of Minnesota Medical School, Minneapolis, 1925; member of the board of directors of the Hennepin County Medical Society; fellow of the American College of Surgeons; on the staffs of St. Andrew's and St. Barnabas hospitals, and the Fairview Hospital, where he died Sept. 27, aged 69, of shock and fracture of the pelvis as the result of a fall.

Anderson, Lester D. Ⓜ Chicago; Chicago Medical School, 1919; served as a member of the staff of the city health department; died in St. Petersburg, Fla., Sept. 25, aged 69, of cerebral hemorrhage.

Babcock, Elmer E., Alden, Iowa; State University of Iowa College of Homeopathic Medicine, Iowa City, 1901; died June 29, aged 83, of arteriosclerosis.

Baker, William Washington Ⓜ Steubenville, Ohio; Meharry Medical College, Nashville, Tenn., 1920; died in the Ohio Valley Hospital Sept. 29, aged 64.

Balch, Franklin Greene Ⓜ Boston; Harvard Medical School, Boston, 1892; served on the faculty of his alma mater; member of the founders group of the American Board of Surgery; member of the American Surgical Association and the American Urological Association; fellow of the American College of Surgeons; served in France during World War I; honorary consultant at Massachusetts General Hospital; on the consulting staffs of Robert Breck Brigham Hospital and Faulkner Hospital, where he died Sept. 23, aged 94, of pulmonary fibrosis.

Barber, Robert Forrest, Sea Girt, N. J.; born in Elizabeth, Oct. 20, 1882; Long Island College Hospital, Brooklyn, 1908; clinical professor emeritus of surgery, State University of New York College of Medicine at New York City, Brooklyn; served in France during World War I and was made a Chevalier of the Legion of Honor by the French government; member of the founders group of the American Board of Surgery; a vice-president of the Kings County Medical Society; fellow of the American College of Surgeons; member of the House of Delegates of the American Medical Association from 1938 to 1941; served on the staffs of the Long Island College Hospital, Kingston Avenue Hospital, and Kings County Hospital; consulting surgeon for the police department; died in the Monmouth Memorial Hospital in Long Branch Oct. 5, aged 75.

Bishop, Harry Arthur Ⓜ Bakersfield, Calif.; Northwestern University Medical School, Chicago, 1938; veteran of World War II; on the staffs of the Mercy, Kern General, and Bakersfield hospitals, and the Memorial Hospital, where he died Sept. 24, aged 48, of multiple pulmonary and brain abscesses.

Booth, Franklin H., Point Pleasant, N. J.; Columbia University College of Physicians and Surgeons, New York City, 1902; veteran of World War I; died Sept. 24, aged 81.

Boyd, Frank, Paducah, Ky.; Rush Medical College, Chicago, 1889; an associate member of the American Medical Association and served as a member of the House of Delegates in 1915; past-president of the Kentucky State Medical Association; fellow of the American College of Surgeons; veteran of the Spanish-American War; at one time county health officer; for many years on the staff of the Illinois Central Hospital and the Riverside Hospital; died in the Western Baptist Hospital Sept. 27, aged 90.

Bruner, Henry Clay, Louisville, Ky.; Hospital College of Medicine, Louisville, 1902; an associate member of the American Medical Association; formerly associated with the Veterans Administration; died in the Kentucky Baptist Hospital Sept. 24, aged 79.

Buchanan, Rogers Ross, Hannibal, Mo.; St. Louis College of Physicians and Surgeons, 1898; practiced in Philadelphia; died in the Levering Hospital Sept. 23, aged 88.

Chapman, William Herbert, Whitney, S. C.; Atlanta College of Physicians and Surgeons, 1906; served on the staff of the Mary Black Memorial Hospital in Spartanburg; died Sept. 24, aged 77, of Parkinson's disease and pyelonephritis.

Conway, John Michael, Spring Valley, Wis.; University of Illinois College of Medicine, Chicago, 1915; veteran of World War I; served on the school board and as health officer; died at his summer home on Lake Tainter, Menomonie, Sept. 22, aged 68, of coronary heart disease.

Crump, John Howard Ⓜ Long Beach, Calif.; New York Medical College and Flower Hospital, New York City, 1937; certified by the National Board of Medical Examiners; veteran of World War II; on the staffs of the Seaside Memorial, St. Mary's, Long Beach General, and the Long Beach Community hospitals; died May 2, aged 52.

Ⓜ Indicates Member of the American Medical Association.

Cuff, William Sherman, St. Paul; University of Minnesota College of Medicine and Surgery, Minneapolis, 1897; on the staff of the Riverview Memorial Hospital, where he died Sept. 25, aged 83, of pneumonia.

Day, Kenneth Knowlton, Waterford, Conn.; Boston University School of Medicine, 1928; practiced in Malden, Mass.; member of the Massachusetts Medical Society; fellow of the American Society of Anesthesiologists; veteran of World War II; served on the staff of the Malden (Mass.) Hospital and the Lawrence Memorial Hospital in London, Conn., where he died Sept. 29, aged 57, of coronary occlusion.

Deemar, Paul Roscoe, Ford City, Pa.; Maryland Medical College, Baltimore, 1907; an associate member of the American Medical Association; veteran of World War I; died in the Butler County Memorial Hospital, Butler, Sept. 24, aged 77.

Ding, George Harvey, Orleans, Mass.; New York Homeopathic Medical College and Hospital, New York City, 1906; an associate member of the American Medical Association; member of the Medical Society of the State of New York; formerly practiced in Brooklyn, where he was on the staff of the Cumberland Street, Bay Ridge, and Methodist hospitals; died in Barnstable County Hospital in Cape Cod Oct. 7, aged 84, of arteriosclerosis and cerebrovascular accident.

Doll, Joseph Edwin, St. Louis; National University of Arts and Sciences Medical Department, St. Louis, 1912; died Oct. 1, aged 72, of arteriosclerosis.

Drake, Eugene Henry Ⓜ Portland, Maine; Medical School of Maine, Portland, 1919; served on the faculty of his alma mater; specialist certified by the American Board of Internal Medicine; a director and past-president of the Maine Heart Association; past-president of the Maine Medical Association; fellow and at one time governor of the American College of Physicians; at one time city physician; veteran of World War II, during which time he was chief consulting cardiologist for the Pacific Fleet, and winner of the Bronze Star for meritorious service aboard the hospital ship USS Solace in the Pacific; for many years associated with the Maine General Hospital, where he was chief of staff from 1937 to 1948, and past-president of the staff; medical consultant, Veterans Administration Hospital in Togus, Webber Hospital, Biddeford, Henrietta D. Goodall Hospital in Sanford, and Eastern Maine General Hospital in Bangor; instrumental in establishing the Blue Shield in Maine; in 1951 the Portland Kiwanis Club gave him a plaque for distinguished service; died in the Maine Medical Center Oct. 4, aged 66, of tetanus and diverticulitis.

Duncan, B. W., Waldron, Ark. (licensed in Arkansas in 1903); died Sept. 19, aged 86, of cerebral thrombosis.

Finney, Horace Maynard Ⓜ Chicago; Chicago Medical School, 1926; an employee of the Chicago Daily News; examining physician for Chicago Typographical Union number 16; died in the Illinois Masonic Hospital Oct. 8, aged 74, of pulmonary embolism.

Glogowska, Jadwiga, Alton, Ill.; Uniwersytet Poznański Wydzial Lekarski, Poznań, Poland, 1949; interned at the Evangelical Hospital and served a residency at the Cook County Hospital in Chicago; died in the Illinois Research Hospital, Chicago, Oct. 6, aged 35, of injuries received in an automobile accident in Madisonville, Ky.

Grant, Hugh D., Bath, Maine; Maryland Medical College, Baltimore, 1904; past-president of the Maine Medical Association; served as city physician; on the staff of the Bath Memorial Hospital; died Sept. 29, aged 87, of pneumonia.

Guion, Clarence Child, New Rochelle, N. Y.; University and Bellevue Hospital Medical College, New York City, 1899; an associate member of the American Medical Association; past-president of the Westchester County Medical Society; for many years on the staff and on the medical board of the New Rochelle Hospital; formerly director of the First Westchester National Bank of New Rochelle and trustee of the People's Bank for Savings; served as associate editor of *Westchester Medical Bulletin;* one of the founders and first president of the New Rochelle Professional Building, serving as member of its board of directors until 1946; died Sept. 30, aged 82, of cerebral thrombosis.

Hamilton, Charles H. Ⓜ Vermont, Ill.; Eclectic Medical Institute, Cincinnati, 1894; died Sept. 25, aged 89.

Harper, George Tinsley Ⓜ Dewey Rose, Ga.; Atlanta School of Medicine, 1910; on the staff of the Elberton–Elbert County Hospital in Elberton; died Sept. 29, aged 72, of coronary thrombosis.

Hobbs, Louis Lyndon, Chapel Hill, N. C.; University of Pennsylvania School of Medicine, Philadelphia, 1916; fellow of the American College of Surgeons; died Sept. 28, aged 75.

Isenberg, Bertice Alvin Ⓜ Lohrville, Iowa; Kansas Medical College, Medical Department of Washburn College, Topeka, 1908; died in the Veterans Administration Hospital, Des Moines, Sept. 20, aged 76.

Jewett, Earl Dayton, St. Paul, Ind.; Illinois Medical College, Chicago, 1904; veteran of World War I; died Sept. 25, aged 78, of a heart attack.

Kahlke, Charles Edwin Ⓜ Benton Harbor, Mich.; born in Rock Island, Ill., Jan. 13, 1870; the Hahnemann Medical College and Hospital, Chicago, 1894; at one time on the faculty of his alma mater;

specialist certified by the American Board of Surgery; fellow founder and life member of the American College of Surgeons, of which he was for many years governor, and from 1918 to 1920 vice-president; served as a vice-president of the Institute of Medicine of Chicago; past-president of the Chicago Surgical Society; once served on the advisory committee to the mayor of Chicago; veteran of World War I; honorary trustee of Chicago Wesley Memorial Hospital; for many years on the staffs of the Cook County Hospital and of the Chicago Memorial Hospital, where he was chief of staff; consultant at the Chicago Home for the Friendless; died Oct. 10, aged 88.

Kass, Albert Joseph Ⓜ Chicago; Loyola University School of Medicine, Chicago, 1940; on the staff of St. Mary of Nazareth Hospital; died Oct. 11, aged 44, of acute coronary occlusion and rheumatic heart disease.

Keiller, Violet Hannah Ⓜ Houston, Texas; born in Edinburgh, Scotland, in 1887; University of Texas School of Medicine, Galveston, 1914; for many years served on the faculty of the Baylor University College of Medicine; at one time on the faculty of her alma mater; specialist certified by the American Board of Pathology; member of the American Society of Clinical Pathologists; honorary member of staff at Hermann Hospital, where she was head of pathology from 1927 to 1951; the association of former interns and residents at Hermann Hospital donated a picture of her which now hangs in the hospital, and they established the Violet H. Keiller Award in her honor; under the fund, a scholarship is awarded each year to an outstanding resident; consultant at M. D. Anderson Hospital and Tumor Institute; died Sept. 24, aged 70, of coronary disease.

Kelso, John Calvin, Canonsburg, Pa.; University of Southern California School of Medicine, Los Angeles, 1900; an associate member of the American Medical Association; past-president of the Washington County Medical Society; physician for the Canonsburg School System for 19 years; veteran of World War I; on the staff of the Canonsburg General Hospital, where he died Sept. 22, aged 82.

Kitlowski, Henry, Pittsburgh; University of Pittsburgh School of Medicine, 1926; specialist certified by the American Board of Otolaryngology; fellow of the American College of Surgeons; member of the Medical Society of the State of Pennsylvania; on the staffs of the St. Francis, Eye and Ear, and Children's hospitals; died Sept. 17, aged 60, of coronary occlusion.

Knope, J. Colman Ⓜ Rochester, N. Y.; University of Buffalo School of Medicine, 1938; veteran of World War II; on the staffs of the Park Avenue Hospital and the Highland Hospital, where he died Sept. 30, aged 51, of myocardial infarction.

Lease, Raymond Essex Ⓜ Oyster Bay, N. Y.; Columbia University College of Physicians and Surgeons, New York City, 1920; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; served as police surgeon for the Nassau County Police Department, a school physician, and health officer of the town of Oyster Bay; on the consulting staff at Meadowbrook Hospital in Hempstead, where he was a member of the board of managers; on the consulting staff of the Community Hospital in Glen Cove, where he died Oct. 1, aged 63.

Lemere, Henry Bassett, Laguna Beach, Calif.; born in Manchester, England, Feb. 1, 1872; University of Nebraska College of Medicine, Omaha, 1898; member of the faculty of his alma mater from 1900 to 1930, at which time he was head of the department of otolaryngology; specialist certified by the American Board of Ophthalmology and the American Board of Otolaryngology; an associate member of the American Medical Association; a life fellow of the American Academy of Ophthalmology and Otolaryngology; a senior member of the American Laryngological, Rhinological and Otological Society and was a contributor to their transactions; in 1936 organized the Beverly Hills Academy of Medicine and was its first president; during World War I ophthalmologist to U. S. Army Base Hospital 69 and served in this country and France in 1918-1919; consultant in ophthalmology to U. S. Army Hospital Center at Mesves, France; on the staff of Cedars of Lebanon Hospital in Los Angeles; died Oct. 6, aged 86, of arteriosclerotic heart disease.

Lytle, Ralph McKay, State Park, S. C.; Jefferson Medical College of Philadelphia, 1912; an associate member of the American Medical Association; served on the staff of the South Carolina Sanatorium; veteran of World War I; died in Columbia Hospital Sept. 27, aged 72, of perforated aneurysm in descending aorta.

MacKillop, Daniel Ⓜ Cambridge, Mass.; Baltimore Medical College, 1902; associated with Mount Auburn and Holy Ghost hospitals; died Sept. 28, aged 82, of cerebral thrombosis.

Maroney, Frederick William, Brooklyn; Tufts College Medical School, Boston, 1918; served for 10 years as associate professor of health and physical education at Teachers College, Columbia University in New York City; joined the Brooklyn College staff in 1941 and was made chairman of the department of health and physical education, named dean of students in 1944, and retired ten years later; died in the Peck Memorial Hospital Oct. 4, aged 74.

McKay, William H., Lackawaxen, Pa.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1908; died in the Wayne County Memorial Hospital, Honesdale, Sept. 25, aged 73, of cardiac decompensation.

Miller, Luther Edwin, Newton, Miss.; Vanderbilt University School of Medicine, Nashville, Tenn., 1954; service member of the American Medical Association; interned at the Greenville (S. C.) Hospital; for two years served with the U. S. Air Force Reserve at Waco, Texas; on the staff of Newton Hospital, where he died Sept. 29, aged 30, of rupture of the aorta.

Morse, George, Ludlow, Mo.; Eclectic Medical Institute, Cincinnati, 1902; died in the Chillicothe (Mo.) Municipal Hospital Oct. 4, aged 87.

Mull, Joseph Harry Ⓜ Rome, Ga.; Medical Department of Emory University, Atlanta, 1916; fellow of the American College of Surgeons; past-president of the Floyd County Medical Society; on the staff of the Floyd Hospital and the McCall Hospital, where he died Sept. 21, aged 67, of myocardial infarction.

Norris, Julia Anna, Minneapolis; Northwestern University Woman's Medical School, Chicago, 1900; retired director of the department of physical education for women at the University of Minnesota; died Sept. 18, aged 83, of myocardial infarction, arteriosclerosis, and hypertension.

Novak, Eduard, Baltimore; Johns Hopkins University School of Medicine, Baltimore, 1917; member of the Medical and Chirurgical Faculty of Maryland; on the staff of the Bon Secours Hospital, where he died Oct. 6, aged 68, of hypertensive cardiovascular disease.

Painter, Thomas Edgar Ⓜ Radford, Va.; Medical College of Virginia, Richmond, 1931; member of the American Psychiatric Association; veteran of World War II; associated with the St. Albans Sanatorium; served as assistant physician and clinical director at the Eastern State Hospital in Williamsburg; formerly on the staff of the Westbrook Sanatorium in Richmond; died in the University of Virginia Hospital, Charlottesville, Sept. 21, aged 54, of carcinoma of the parotid gland.

Parker, Charles Edward, Corpus Christi, Texas; St. Louis College of Physicians and Surgeons, 1906; veteran of World War I; died Sept. 18, aged 76.

Pater, Joseph Louis Anthony Ⓜ Hamilton, Ohio; St. Louis University School of Medicine, 1930; veteran of World War II; on the staffs of the Fort Hamilton Hospital and the Mercy Hospital, where he died Sept. 30, aged 52, of cancer.

Patterson, Charles Luther, Westside, Iowa; Rush Medical College, Chicago, 1899; veteran of World War I and the Spanish-American War; died in the Veterans Administration Hospital, Omaha, Sept. 14, aged 89.

Petersen, Arthur Berg Ⓜ Spokane, Wash.; University of Oregon Medical School, Portland, 1947; specialist certified by the American Board of Internal Medicine; after an internship at the Wesley Memorial Hospital in Chicago, served a fellowship at the Mayo Clinic in Rochester, Minn.; captain in the Medical Corps, U. S. Air Force, during World War II and from 1951 to 1953; on the staff of the Sacred Heart Hospital; died in Seattle Sept. 5, aged 37.

Phillips, Edward Milliken Ⓜ Wheeling, W. Va.; Jefferson Medical College of Philadelphia, 1911; member of the Southeastern Surgical Congress and the American Association of Railway Surgeons; fellow of the American College of Surgeons; on the staffs of the Wheeling and Ohio Valley General hospitals; died Sept. 18, aged 72, of coronary sclerosis.

Pittenger, Earle Alexander Ⓜ Aberdeen, S. D.; Rush Medical College, Chicago, 1920; fellow of the American College of Surgeons; past-president and formerly councilor of the South Dakota State Medical Association; served as member of the city board of health; division surgeon for the Milwaukee Railroad; on the staff of St. Luke's Hospital; died in Rochester, Minn., Sept. 24, aged 66, of aortic stenosis and diabetes mellitus.

Powers, Earl Jennings Ⓜ Winston-Salem, N. C.; University of Cincinnati College of Medicine, 1932; fellow of the International College of Surgeons; on the staffs of the City Memorial and Kate Bitting Reynolds Memorial hospitals; died Sept. 21, aged 53, of cerebral thrombosis.

Potter, Henry Bertram Ⓜ Wakefield, R. I.; University of Pennsylvania Department of Medicine, Philadelphia, 1899; before the United States entered World War I, went to France with the Harvard University Surgical Unit and became a captain in the Royal Army Medical Corps; received a citation from the King of England; for many years college physician for Rhode Island State College; senior surgeon on the staff of South County Hospital, where he died Sept. 15, aged 82, of embolism following a prostatectomy.

Rahming, Harry Ellsworth II Ⓜ Denver; University of Colorado School of Medicine, Denver, 1953; interned at St. Luke's Hospital; served a residency at Veterans Administration Hospital; associated with the Children's Hospital; served in the medical corps of the U. S. Army Reserve; died Sept. 14, aged 30, of cyanide poisoning, self-administered.

Reese, John Davies Ⓜ Philadelphia; Jefferson Medical College of Philadelphia, 1925; clinical professor of plastic and reconstructive surgery at his alma mater; specialist certified by the American Board of Plastic Surgery; member of the American Association of Plastic Surgeons and the American Society of Plastic and Reconstructive Surgery; chief plastic surgeon, Philadelphia General Hospital; consultant in plastic surgery at Montgomery Hospital in Norristown, Quakertown (Pa.) Community Hospital, and Veterans Administration Hospital; on the staff of the Jefferson Hospital, where he died Oct. 7, aged 65.

Rumore, Samuel Charles Ⓜ Coral Gables, Fla.; Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1928; member of the Medical Society of the State of New York; formerly practiced in Brooklyn, where he was on the staffs of the Prospect Heights and Cumberland hospitals; died Sept. 22, aged 58, of acute coronary thrombosis and congestive heart failure.

Sanders, Matthew J., Lawton, Okla.; College of Physicians and Surgeons, Dallas, Texas, 1906; died Sept. 13, aged 74.

Shepard, Charles Angell Ⓜ Major, U. S. Army, retired, Denver; University of Buffalo School of Medicine, 1896; veteran of World War I; entered the medical corps of the U. S. Army in 1920 and retired May 31, 1934; died in the Veterans Administration Hospital Sept. 16, aged 86, of cerebral thrombosis.

Shoemaker, J. Donald, Mount Olive, Ill.; Chicago Medical School, 1947; died in the Community Memorial Hospital, Staunton, Sept. 23, aged 50.

Siegel, Morton Thelman Ⓜ West Covina, Calif.; Ohio State University College of Medicine, Columbus, 1951; certified by the National Board of Medical Examiners; specialist certified by the American Board of Ophthalmology; veteran of World War II; interned at the Los Angeles County Hospital in Los Angeles, where he served a residency; died Sept. 15, aged 36.

Silverman, Eli, Boston; St. Louis College of Physicians and Surgeons, 1926; Middlesex College of Medicine and Surgery, Waltham, Mass., 1930; on the staffs of the Peter Bent Brigham Hospital and the Boston City Hospital; died Sept. 16, aged 66.

Smith, J. Harvey, Miami, Fla.; Meharry Medical College, Nashville, Tenn., 1905; died Sept. 16, aged 69.

Smith, Wilbur Forrest Ⓜ Indianapolis; Indiana University School of Medicine, Indianapolis, 1921; member of the American Academy of General Practice and the Aero Medical Association; veteran of World War I and in World War II served for two years as chief of the Civil Aeronautics Administration medical standards board in Washington, D. C.; for many years chief examiner for the Civil Aeronautics Commission of Indiana; on the staff of the Methodist Hospital; died in the Whitley County Memorial Hospital, Columbia City, Sept. 10, aged 68, of bleeding duodenal ulcer.

Smith, William L., Denison, Texas; New York Homeopathic Medical College and Hospital, New York City, 1891; died Sept. 22, aged 90.

Southworth, Franklin Chester Jr., Framingham, Mass.; Harvard Medical School, Boston, 1924; specialist certified by the American Board of Psychiatry and Neurology; certified by the National Board of Medical Examiners; served on the faculty of the University of Buffalo School of Medicine; veteran of World War II; in 1926 appointed medical superintendent of the Woodside Cottages; formerly on the staffs of the Millard Fillmore and the Veterans Administration hospitals in Buffalo; on the consulting staff, Framingham Union Hospital, where he died Sept. 18, aged 60.

Spencer, Harry Dee, Idaho Falls, Idaho; State University of Iowa College of Medicine, Iowa City, 1897; fellow of the American College of Surgeons; past-president of the Idaho State Medical Association; veteran of World War I; on the staffs of the Idaho Falls Latter-Day Saints' Hospital and the Sacred Heart Hospital; died Sept. 17, aged 83, of pulmonary embolism following an automobile accident.

Sprunk, John Paul, Detroit; Detroit College of Medicine and Surgery, 1920; on the staff of the Grace Hospital; died Sept. 8, aged 76, of a cerebrovascular accident.

Stanley, J. Zeph Ⓜ Carmi, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1910; veteran of the Spanish–American War; on the staff of the Carmi Township Hospital; died in the Deaconess Hospital, Evansville, Ind., Sept. 15, aged 76, of coronary occlusion.

Strother, Edwin Bower Ⓜ Dallas, Texas; Medical Department of Tulane University of Louisiana, New Orleans, 1901; served on the staff of the Methodist Hospital; died Sept. 13, aged 84, of arteriosclerotic heart disease.

Tait, Edwin Forbes Ⓜ Norristown, Pa.; born in Philadelphia Aug. 25, 1894; University of Minnesota Medical School, Minneapolis, 1940; associate professor of ophthalmology at Temple University School of Medicine, Philadelphia; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology, Philadelphia College of Physicians, Association for Research in Ophthalmology, and the Pan-American Association of Ophthalmology; chairman, conservation of vision committee, Pennsylvania Academy of Ophthalmology; a vice-president and chairman of the economics committee, Medical Society of the State of Pennsylvania; fellow of the American College of Surgeons; co-founder of the National Medical Foundation for Eye Care; author of "Textbook of Refraction"; served on the staff of the Temple University Hospital in Philadelphia; consultant, North Penn Hospital in Lansdale; chief of the eye clinic of Montgomery Hospital, where he died Sept. 23, aged 64, of arteriosclerotic heart disease.

Takacs, Henry, Miami, Fla.; University of Michigan Medical School, Ann Arbor, 1920; died Sept. 16, aged 71, of cancer of the colon.

Thomas, Francis Xavier Ⓜ Feasterville, Pa.; Jefferson Medical College of Philadelphia, 1947; served on the staff of the Burlington County Hospital in Mount Holly; died Sept. 28, aged 41, in an automobile accident.

Vining, Harriet Augusta, Hastings, Mich.; University of Michigan Homeopathic Medical School, Ann Arbor, 1890; died July 12, aged 89, of a cerebral vascular accident and cardiac decompensation.

Voskuil, Anthony Ⓜ Santa Barbara, Calif.; Milwaukee Medical College, 1907; formerly practiced in Cedar Grove, Wis., where he was health officer; died Sept. 15, aged 81, of cerebral thrombosis.

Weber, Harry Matthew Ⓜ Rochester, Minn.; born in Lewistown, Mont., June 30, 1899; University of Minnesota Medical School, Minneapolis, 1926; interned at St. Joseph's and Ancker hospitals in St. Paul; entered the Mayo Foundation as a fellow in radiology in January, 1927; in October, 1931, became a member of the staff of the clinic as a consultant in roentgenologic diagnosis and in July, 1951, became head of the section of diagnostic roentgenology; appointed an instructor in radiology in the Mayo Foundation, Graduate School, University of Minnesota in 1932, and was advanced to professor in 1954; since 1935 a member of the medical corps of the U. S. Naval Reserve and was assigned to active duty in the grade of lieutenant commander, on Dec. 26, 1941, at the Naval Hospital in Corona, Calif.; released to civilian life on Aug. 12, 1942; specialist certified by the American Board of Radiology; vice-chairman of the Section on Radiology of the American Medical Association from 1947 to 1949; president of the Minnesota Radiological Society in 1940 and the American Roentgen Ray Society, 1953-1954; fellow of the American College of Radiology and consultant to the committee on x-ray department planning in 1951; member of the Radiological Society of North America, American Gastroenterological Association, Sigma Chi, and Phi Rho Sigma; honorary member of the Detroit Roentgen Ray Society, the St. Louis Medical Society, and the Society of Radiology and Physical Therapy of Havana, Cuba; in 1937 received the first award for his exhibit at the Fifth International Congress of Radiology; gave the Fred Hodges Memorial Lecture at the University of Michigan in 1958; on the staffs of the Rochester Methodist Hospital and the St. Mary's Hospital, where he died Oct. 4, aged 59, of a heart attack.

Williamson, Gladys Richarda Ⓜ New Orleans; University of Edinburgh Faculty of Medicine, Scotland, 1916; formerly on the faculty of Tulane University School of Medicine; member of the American Academy of Pediatrics; fellow of the American College of Physicians; chief of pediatrics at Sara Mayo Hospital; on the staffs of the Southern Baptist, Sara Mayo and Charity hospitals; died Sept. 19, aged 69.

Willoughby, Gordon Leslie Ⓜ Flint, Mich.; University of Manitoba Faculty of Medicine, Winnipeg, Man., Canada, 1926; veteran of World War II; member of the Flint Academy of Surgery; on the staffs of Hurley, McLaren, and St. Joseph hospitals; died Sept. 24, aged 58, of heart disease.

Wilson, George Hancock, Lexington, Ky.; born in 1884; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1910; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; past-president of the Fayette County Medical Society; veteran of World War I; for many years a member of the executive board of the Alumni Association of the University of Kentucky and served two terms as president of the association; served as a member of the board of trustees of the University of Kentucky; for many years medical director of the Lexington city schools; on the staffs of the St. Joseph's, Good Samaritan, and Central Baptist hospitals; died Sept. 26, aged 74, of coronary thrombosis.

Wilson, Marion Childress, Miami, Fla.; Vanderbilt University School of Medicine, Nashville, Tenn., 1912; an associate member of the American Medical Association; specialist certified by the American Board of Obstetrics and Gynecology; veteran of World War I; at one time a medical missionary in Turkey; founder and first president of the Miami Obstetrics and Gynecology Society; on the staffs of James M. Jackson Memorial and St. Francis hospitals in Miami Beach; died Sept. 13, aged 72, of chronic myocarditis.

Wyche, George Griffin Jr. Ⓜ Alice, Texas; Temple University School of Medicine, Philadelphia, 1943; past-president of the Brooks–Duval–Jim Wells Counties Medical Society; member of the American Academy of General Practice; veteran of World War II; staff member of the Physicians and Surgeons Hospital; aged 40, instantly killed in a private plane crash Sept. 9.

Young, Roy Lowry Ⓜ Warren, Pa.; Jefferson Medical College of Philadelphia, 1905; past-president of the Warren County Medical Society; veteran of World War I; died Sept. 11, aged 78, of cancer.

FOREIGN LETTERS

AUSTRIA

Cortisone for Malignant Hemoblastoses.—At the meeting of the Society of Physicians in Vienna on Oct. 10, Dr. A. Stacher reported on 11 patients with malignant hemoblastoses who were given 250 to 500 mg. of prednisolone by mouth daily for 10 days. This treatment with large doses showed no advantage over the therapy with small doses (30 to 50 mg. daily in four patients with acute granulocytic leukemia). Five patients with lymphogranulomas had excellent remissions which lasted two or three months. One patient with lymphosarcoma showed good subjective improvement, while the mediastinal tumor receded only very slowly. No objective improvement could be achieved in a patient with carcinoma of the thymus. Side-effects, particularly concerning coagulation, in seven patients who had thrombopenia with hemorrhagic diatheses were observed. In one patient with acute leukosis a gastric ulcer developed. This was controlled with antacids. Since the cost of this therapy is very high, it should be used only if strongly indicated.

Marrow Biopsy.—At the same meeting, Drs. R. P. Königstein and G. Mähr described a method that facilitates the histological examination of marrow specimens obtained by sternal puncture. They mix 2 or 3 cc. of the aspirate with about the double quantity of isotonic sodium citrate solution then centrifuge. A top layer consists of tissue particles, the middle layer of serum and citrate, and the bottom layer of blood corpuscles. The large amount of fat contained in the medullary tissue is responsible for this behavior. Only if there is a small amount of fat or none at all in the medullary tissue can tissue fragments be found in the bottom layer with the corpuscles. These tissue fragments can be isolated by suspending them again in physiological sodium chloride solution and by repeated centrifugation. The histological work is carried out according to the ususal paraffin method. The occurrence of metastatic tumor and hyperplasia of the reticulohistiocytary system or of the lymphatic system in selected cases produces characteristic histological findings.

CANADA

Coxsackie Infection.—In a fairly well detached suburb of recent development, east of Toronto, an epidemic of an illness with fever, malaise, and sore throat attacked about 60 persons in the summer of 1957. A group from the Toronto School of Hygiene (*Canad. M. A. J.*, 79:615, 1958) recovered a virus having the characteristics of group A Coxsackie virus from 22 of 31 patients tested. The patients had distinctive ulcers in mouth and throat, and a bullous eruption arising from a macular exanthem. This condition is considered to represent a new clinical syndrome. Of affected households, 52% of the members became ill, but the illness was mild. Children were particularly prone to infection. In three patients further confirmation of the theory that this was a new type of Coxsackie infection was obtained by the demonstration of a specific antibody response to the related Coxsackie virus A type 16.

Myocarditis due to Sulfonamide Therapy.—Three veterans treated in Sunnybrook Hospital, Toronto, were found at autopsy to have signs of a peculiar acute interstitial myocarditis of a type seen in drug-induced hypersensitivity reactions. There was a characteristic accumulation of inflammatory cells throughout the heart muscle, with histiocytes and eosinophils predominating, and a certain predilection for perivascular areas. In two patients lesions were so severe as to be presumed the cause of death. Each of the patients had recently received the relatively new sulfonamide, sulfamethoxypyridazine, for a urinary infection. Blanchard and Mertens (*Canad. M. A. J.*, 79:627, 1958) suggested that this drug was responsible for these unusual changes. All three cases occurred within a relatively short time, and similar heart lesions had not been seen previously at this hospital.

Rehabilitation.—In a monograph, E. A. Dunlop, secretary of the Canadian Arthritis and Rheumatism Society, outlined a proposed plan for national action in the field of rehabilitation. He stated that rehabilitation is a social service which more than repays its cost through additional tax revenue over and above savings in public assistance and disability allowances. Certain favored classes of the disabled such as the blind, the veterans, and the injured workmen, have a comprehensive rehabilitation service while others have none. The author pleads that no social justification can be found for thus dividing the disabled into two classes. Like education, rehabilita-

tion should include all the population concerned. Moreover, the voluntary agencies cannot be expected to cope with this huge task. The federal government should move into this field. Mr. Dunlop found three reasons why a nationwide policy has not been developed: 1. There is lack of assurance that federal grants will continue to match provincial expenditures. 2. There is a lack of clearcut federal policy. 3. Administrative responsibility in the federal government is divided between four or five separate divisions of two government departments. He urges the passing of a Disabled Persons Rehabilitation Act by the federal government, as a foundation on which a comprehensive nationwide program can be erected.

Influenza.—The Dominion Bureau of Statistics issued some information on the characteristics and trends of the influenza epidemic in Canada in 1957, in a monograph entitled "Influenza in Canada." The spread of the disease was peculiar in that it hit two central provinces (Ontario and Quebec) first, appeared on both the west and the east coasts three or four weeks later, and then invaded such intervening areas as Alberta last. This differs from the pattern in 1951, when the illness appeared practically simultaneously in all 10 provinces. The epidemic lagged behind the similar epidemic in the United States whence it presumably arrived, though once established in Canada it soon ran its course, lasting roughly three months from the beginning of September, 1957, to the end of November, with a peak during the second and third weeks of October (a week or two before the peak was reached in the United States). The incidence among civil servants varied from a high of 1,632 in Montreal to a low of 723 in Winnipeg. It is estimated that three million Canadians (18% of the population) were affected; children were particularly involved, and there was up to 90% involvement in Indian reservations and in some northern settlements.

Hemolytic Disease of the Newborn.—Thanks to the initiative of the Ontario Medical Association, later backed up by the provincial department of health and the Junior Red Cross, the province of Ontario now has an organized program for dealing with cases of hemolytic disease of the newborn. This program is described in a brochure prepared by the Committee on Child Welfare of the Ontario Medical Association. Briefly the scheme is as follows: a physician may have Rh screening of his pregnant patients made at one of several laboratories attached to treatment center hospitals, at laboratories of the Ontario Department of Health, or at Canadian Red Cross Transfusion laboratories. For follow-up titrations of antibodies in patients in whom these are discovered, a number of treatment center hospital laboratories are available, as well as the Red Cross laboratories and certain health department facilities. There are also five reference laboratories for elucidation of difficult cases, for personnel training in technique, and for general consultation. If possible, the Rh-sensitized mother will be delivered in a treatment center hospital, which is equipped and staffed to give postnatal care. If the procedure outlined is followed by all Ontario physicians, it could reduce the mortality from hemolytic disease of the newborn to 5% or less and could obviate most or even all of th ecomplications.

DENMARK

Danish Medical Association.—From time to time the Central Committee of the Danish Medical Association tells its members how it serves them. The latest of these accounts (*Ugeskrift for læger,* Sept. 4, 1958) shows how often requests for help have to be refused because they are outside the purview of the Association. For example, one of its functions is to help draw up contracts between physicians with a view to avoiding forensic loopholes, but when such help is not requested, and a contract has been challenged, the Association is under no obligation to mend matters. Its self-imposed duties are great and varied, with its function as buffer between the health insurance authorities and individual members of the medical profession taking much of its time. These authorities may complain that certain physicians are too liberal in their prescription of expensive foreign drugs when Danish alternatives are much cheaper. In this respect some districts are distinguished by clusters of physicians who with few exceptions are profligate with expensive prescriptions.

The Association has also to advise on the merits of new drugs. In the past year 174 such applications were made to the Association. It also is responsible for the qualifications of chiropodists, 33 of whom were authorized by it to act as such in the past year. A comparatively new function of the Association is to grant certificates of proficiency to physician's secretaries. This highly specialized service, requiring a happy blend of office routine and medical problems, has not hitherto been given the appreciative recognition it deserved, and in January, 1958, the first applications for such certificates were received. Most of the 274 applicants were already occupied in this service, but in many of these cases supplementary training was required before the certificate could be conferred.

Tetanus Antitoxin.—Between Oct. 1, 1955, and Sept. 30, 1956, the Sundby Hospital emergency service dealt with 14,702 accident cases in 1,656 of which prophylactic injections of tetanus antitoxin were indicated and in 1,343 of which they were given. To ascertain how these 1,343 had reacted, Samsöe-Jensen and Zachau-Christiansen (*Ugeskrift for læger,* Sept. 11, 1958) sent a questionnaire to each of them about a year later, soliciting information on such subjects as side-effects or complications, time and duration, incapacity for work, and whether they had or had not been given such prophylactic treatment previously. Only 70 failed to answer. Only 64 of the 1,273 who answered had experienced side-effects, which in 20 cases could be described as serum sickness. A reaction at the site of the injection was in some presumably of an allergic character. Other reactions were urticaria, adenitis, or articular symptoms. In only three patients were the side-effects prolonged. More than 33% of those given tetanus antitoxin had received similar treatment earlier, some several times, so the risk of serum sickness on this account was slight.

Health of Denmark.—A comparison of the behavior of the reportable diseases in 1956 and 1957, respectively, by Dreyer and Frandsen (*Ugeskrift for læger*, Sept. 18, 1958) showed how greatly some of them fluctuated from one year to the next. This was notably the case with influenza, whose incidence was 5 times greater in 1957 than in 1956, while its case fatality rate was 10 times higher. This may partly explain why the total death-rate rose from 8.9 per 1,000 in 1956 to 9.3 in 1957. In this year the deaths from all forms of tuberculosis fell to 4.4 per 100,000, more than trebling the number of deaths from traffic accidents. In the same year malignant disease plus arteriosclerosis and degenerative disease of the heart accounted for 46% of all the deaths. Accidents accounted for 4.8% of all the deaths in 1957. Since 1954 the reports of gonorrhea showed a slight tendency to fall, but there were still 7,447 reported cases in 1957. The reports of acquired syphilis fell from 104 in 1956 to 48 in 1957. Between the same years the reports of acute poliomyelitis fell from 191 to 26, only 10 which were paralytic. Diphtheria seems to have been wiped out, temporarily at any rate, for not a single case was reported in 1956 or 1957.

Frequency of Thromboembolic Lung Lesions.—Investigations into the frequency of thromboembolic lung lesions in adults examined post mortem have yielded divergent findings, with about 10% recorded by T. H. Belt in 1934, and 23% by T. J. Moran in 1947. In *Nordisk medicin* for Oct. 2, Bang and co-workers published their findings, which concerned postmortem examinations in 1954 and 1955 on 1,788 patients over the age of 15. In 271 cases (15%), thrombi, emboli, or infarctions were found. In only 16% of these cases had this condition been diagnosed during life, and the failure to do so was particularly noticeable in the case of elderly, decrepit patients. A scrutiny of the clinical record of each of these patients led to the conclusion that the lung lesions would not have been so often overlooked had they been kept in mind when tachycardia came on suddenly with increasing cardiac insufficiency and an inexplicable rise of temperature not responding to antibiotics. The antemortem rate of correct diagnoses was highest for the 84 patients in whom the course of events had been rapid, with less than 24 hours between the onset of symptoms and death.

Cough Syncopy.—At a meeting of the Danish Society for Internal Medicine (reported in *Nordisk medicin* for Oct. 2) several speakers discussed the importance to traffic accidents of cough syncopy Four such cases were recently dealt with by a invalid board in one year. In the case mentioned by Dr. M. Schwartz the patient was a 45-year-old professional chauffeur. This mishap overtook him o three occasions while driving, and during one o them he drove into a house. His license to driv had to be cancelled. Another speaker who referre to four similar cases with patients aged 45, 49, 6 and 62, respectively, pleaded for a more critic medical examination of prospective drivers. H wished to extend it not only to possession of th main senses and general mobility, but also to freedom from brief lapses of consciousness while th driver is at the wheel. Derbes and Kerr in an earli monograph showed that the victims of this cond tion were nearly always men between the ages o 40 and 70, suffering from chronic asthma, bronchitis, and emphysema. They were also often heavy men addicted to tobacco.

INDIA

Determination of Sex.—Gadgil and Deodhar (*Indian J. M. Sc.* **12:**6 [June] 1958) stated that the presence or absence of a specific chromatic mass in the nuclei of somatic cells can be used to determine the sex of an individual. This mass has been called nucleolar satellite when found in nerve cells and sex chromatin in other somatic cells. The authors studied smears from different tissue fluids with a view to determine sex from examination of the cells and their nuclei. Thus smears of buccal mucosa were collected from 100 males and 100 females of ages ranging from 10 to 50 years; 95 smears from amniotic fluid obtained by puncture just before delivery were also similarly studied, and routine blood films from 150 persons with normal total and differential leukocyte counts were prepared. The oral smears showed two types of cells—large with pyknotic nuclei and smaller with vesicular nuclei. The latter were examined for the presence or absence of sex chromatin mass. In all males the chromatin was in the form of small particles of irregular size distributed evenly in the protoplasm with a predilection for nuclear membrane; in females the typical feature of the nucleus was the presence of a distinctly hyperchromatic mass planoconvex in shape.

The amniotic fluid smears showed three types of cells—very large with pyknotic nuclei in different stages of degeneration, basal cells, and precornified cells. The chromatin mass in the latter two types of cells from female infants was at the nuclear membrane in most of the cells. The nucleus of the polymorphonuclear cells in blood smears showed the typical appendage or drumstick in females in 97% of cases. Smear examination of blood helped to arrive at a correct diagnosis of sex in all the 100 smears studied from males, while the diagnosis was missed in 3 of the 100 females. The study of smears from oral mucosa and the blood could easily be used as a routine procedure. The results of examination of oral smears were more accurate than the study of polymorphonuclear cells from blood smears. Although amniotic fluid smears gave accurate results, the procedure of obtaining the fluid at an early stage is not without risk both to the mother and to the fetus.

Treatment of Tetanus.—Patel and Joag (*Indian J. Med. Sc.* 12:6 [June] 1958) stated that the value of antitetanus serum in the treatment of tetanus has been established conclusively by animal experiments. There are, however, variable opinions regarding the effective dose. The authors studied a series of patients treated with varying doses of the serum. Thus, 816 patients were given a total dose of 240,000 units of antitetanus serum, 243 received 120,000 units, and another 243 were given 60,000 units. The difference in results in the three groups was not significant enough to show any correlation between mortality and dose level. Thus, results with 60,000 units were as good as those with 240,000 units. Even the percentage of deaths occurring after 48 hours was the same in the three groups. The advantages of using a smaller dose, besides being less costly, were that there was less pain at the injection site and the chances of abscess formation were reduced.

Treatment of Cancer.—There are 40 hospitals in India with the latest equipment for the treatment of cancer. The steps taken by the government for checking the spread of cancer included (1) the establishment of the Indian Cancer Research Center in Bombay in 1952 for postgraduate teaching and for research in cancer and allied subjects, (2) taking over by the government of the Chittaranjan National Cancer Research Center, Calcutta, in 1957, (3) grants-in-aid to five institutions treating cancer, (4) taking over by the government in 1957 of the Tata Memorial Hospital, Bombay, to facilitate research work at the Indian Cancer Research Center, and (5) the installation of three cobalt bomb therapy units in the Tata Memorial Hospital, Bombay, the Chittaranjan National Cancer Research Center, Calcutta, and the Christian Medical College, Ludhiana, respectively.

Tuberculosis Survey.—The preliminary report of the survey up to June 1956 by the Indian Council of Medical Research showed that tuberculosis was prevalent in villages, small towns, and cities; 2% of the people in the areas covered had the disease. It was concluded that (1) the morbidity of tuberculosis varies from 7 to 30 per 1,000 persons in different areas, (2) the prevalence of tuberculosis is not so marked as originally expected, (3) the morbidity rates are lower for females than for males, (4) the prevalence of tuberculosis among the persons of the age group of 45 years and above was much higher than that for the age group of 5 to 34 years, and (5) bacteriologically positive cases varied from 1 to 11 per 1,000 persons in different areas. The government formulated a national tuberculosis control program to include intensification of the BCG vaccination campaign, upgrading of 300 tuberculosis clinics to provide or expand facilities for diagnosis and domiciliary treatment, establishment of 15 tuberculosis demonstration and training centers, establishment of 4,000 tuberculosis isolation beds, and establishment of eight follow-up centers for tuberculosis patients.

Spider Nevi and Liver Disease.—H. Singh and coworkers (*Current M. Pract.* 2:8 [Aug.] 1958) stated that spider nevi have often been noticed in association with liver disease. They may disappear with improving hepatic function, while the appearance of fresh nevi suggests progression of parenchymal liver damage. Spider nevi are, however, rare in Indian patients suffering from hepatic disease. Thus, of 250 consecutive patients with hepatic cirrhosis, only 4 showed the presence of such nevi. The authors studied 31 patients with portal cirrhosis including 2 with postnecrotic scarring to find out whether percutaneous administration of estrogen could lead to the production of spider nevi in a larger number of patients with liver damage. Skin areas were treated with 1% ethinyl estradiol ointment in a lanoline base or alcoholic solution. In 20 patients the application was made for 7 to 10 consecutive days and in the rest for 5 days. They were followed for 5 to 27 days after the last application. None of the patients developed spider nevi in the treated areas or in the untreated parts. Thus, the inunction of estrogen had little effect in the production of spider nevi.

Acetylcholine Content of Intestine.—B. G. Bose and co-workers (*Indian J. M. Sc.* 12:7 [July] 1958) reported that the different segments of intestine showed different inhibitory responses to epinephrine and arterenol, epinephrine having a greater inhibitory action on the ileum and arterenol on the colon. These variations may be related to the acetylcholine content of these tissues. The authors therefore studied the inhibitory responses and the acetylcholine content of segments of duodenum, jejunum, and colon of adult male albino rats. The acetylcholine content of the different segments showed significant variation, and, on an average, the colon contained less acetylcholine as compared to duodenum and jejunum. The inhibitory response was maximal in the jejunum and lowest in colon. Thus, a correlation was found to exist between the degree of inhibitory response and the content of acetylcholine in the intestinal segments. Epinephrine caused greater inhibition of the tissues containing more acetylcholine than arterenol. As arterenol is not affected much by acetylcholine content, its inhibitory action on the colon, which is poorer in acetylcholine, is more predominant as compared to that of epinephrine.

Tropical Eosinophilia.—R. S. Mehta (*Indian J. M. Sc.* 12:7 [July] 1958) studied the electrocardiographic tracings in 80 patients with classic tropical eosinophilia and compared them with the tracings from 50 healthy adults. In each case three standard limb leads, three unipolar limb leads, and six unipolar chest leads were taken. Changes of hyperkalemia were seen in about 46%. The serum potassium level was estimated in all but nine cases, but there was no exact correlation between the serum potassium level and the electrocardiographic evidence of hyperkalemia, although the incidence of hyperkalemic changes definitely rose when the serum potassium level was above 20 mg. per 100 ml. The incidence of hyperkalemia rose *pari passu* with the total eosinophil count up to a certain level; 44% of the tracings showed either left or right ventricular preponderance, the distribution being 31.25% and 12.5% respectively. Thus, the incidence of left ventricular preponderance was 2.5 times that of the latter. Vertical heart was present in 80% of the series and even in those with left ventricular preponderance. Among the controls, vertical heart was present in 56%. Of the 80 patients, 13 showed tachycardia, the pulse rate varying from 105 to 140 per minute, while 2 showed bradycardia, the rate being 52 and 54 respectively. Nine tracings from the patients and one from the controls showed low voltage. In 14 patients the P wave was more than 2.5 mm. in height and suggestive of "P" pulmonale, while in 10 it was small, flat, or biphasic. Conduction changes were seen in 20 patients and 10 controls, consisting of intraventricular conduction disturbances with marked slurring of the ventricular complex.

Bacitracin and Amebiasis.—DeMelloe and Patel (*Indian J. M. Sc.* 12:6 [June] 1958) stated that bacitracin, in addition to its antibiotic action, also possesses amebicidal action. As it is not absorbed from the intestine, it exerts maximal amebicidal action and also eliminates the secondary invading organisms. The authors studied the effect of bacitracin alone and in combination with streptomycin in persons with asymptomatic amebiasis who were passing cysts or vegetative forms of Endameba histolytica. Because the antibacterial spectrum of bacitracin resembles that of penicillin, streptomycin was selected for its action on gram-negative organisms. Stool examination was repeated after a saline purgative after three weeks of treatment on three occasions at intervals of one week. Persons with all three results negative were considered cured. Bacitracin alone was used in three different dosage schedules—2 tablets of 5,000 units each, four times a day for seven days on five patients; 2 tablets of 12,500 units each, four times a day for three days on four patients; and 2 tablets of 12,500 units each, four times a day for seven days on four patients. When used in combination with streptomycin, each tablet contained 5,000 units of bacitracin and 125 mg. of streptomycin. Two such tablets were given four times a day for 10 days to 11 patients. The results on the whole were variable when bacitracin alone was used, the cure rate being much higher with the combination than with the single drug. Thus 9 of the 11 patients treated with the combination were cured. Although the dose of bacitracin in combination is small, it probably has a synergistic action with streptomycin in clearing the amebic infection.

NEW ZEALAND

New Approach for Hiatal Herniorrhaphy.—J. Borrie (*British Medical Journal*, September 20, 1958, p. 728) reported that, although the right-sided approach is a standard procedure for performing esophagectomy for carcinoma of the midesophagus, no record has been encountered of the use of this approach for repairing hiatal hernias. The author described an occasion when, because of a misdiagnosis, a right thoracotomy was performed, and a hiatal hernia was unexpectedly found and successfully repaired through the right pleural cavity. The fact that this right-sided approach proved as satisfactory as that from the left side indicates that the former is another possible route for the repair of such lesions.

Thyroid-Stimulating Hormone.—Dr. D. D. Adams (*Journal of Clinical Endocrinology*, vol. 18, p. 699, 1958) reported that when investigated for their content of thyroid-stimulating hormone (TSH) some human serums induced abnormal responses in the TSH assay. In the normal response, the I^{131} level in the guinea pig's plasma was higher 3 hours after the intravenous injection of the TSH than it was 16 hours after. In the abnormal response, elicited by serums from some patients with thyrotoxicosis, the reverse occurred—the guinea pig's plasma I^{131} level was higher 16 hours after the intravenous injection of the serum than it was 3 hours after. These observations prompted an investigation of the mechanism of the abnormal response and the type of response elicited by the TSH present in human, bovine, and murine pituitary glands, and in the blood of thyroidectomized rats and a variety of human subjects. Since the size of the abnormal response was not reduced by injection into the test guinea pig of a massive dose of thyroxine, it was unlikely that the abnormal TSH response was due to blockage of the thyroxine-inhibition of endogenous TSH secretion from the test guinea pig's pituitary gland. When U. S. P. thyrotropin reference substance was added to a serum that elicited the abnormal TSH response, the magnitude and time course of the response induced by the mixture indicated that the two components acted independently. It is probable, therefore, that the abnormal response was a manifestation of the presence of an abnormal TSH.

The finding of abnormal responses only to serums from patients with thyrotoxicosis makes it probable that the abnormal TSH had some relationship to this disorder, but the data collected so far were not adequate to exclude with certainty the possibility that abnormal TSH might occur in conditions other than thyrotoxicosis. It has been shown that serums from some patients with exophthalmos and hyperthyroidism had the power to increase markedly the acinar cell height of the thyroid glands of thyroxine-injected guinea pigs. In the light of the findings of the present investigation it is likely that these serums contained the abnormal TSH, which apparently affected thyroid morphology in a way similar to that of normal TSH. It may be that abnormal TSH differed from the normal in the length of its stay in the blood. Possibly it was normal TSH combined with some other material. Abnormal TSH might also be present in all cases at a level too low to be detected by the present assay procedure. It is possible, therefore, that the abnormal TSH plays a causative role in the hyperthyroidism of thyrotoxicosis. It may also be implicated in the cause of exophthalmos. It is possible that the exophthalmos-producing substance found by Dobyns and Wilson in 1954 in the serum of patients with progressive exophthalmos, was the abnormal TSH. The site of production of the abnormal TSH remains unknown, but suspicion naturally falls on the pituitary.

UNITED KINGDOM

Intra-articular Hydrocortisone.—The intra-articular injection of hydrocortisone acetate is generally regarded to be of value in the treatment of rheumatoid arthritis, and most patients seem to derive subjective, even if transient, benefit. Chandler and Wright, however, reported that despite a good clinical response to injections of hydrocortisone derivatives, radiologic deterioration, sometimes extensive, occurs in the knees of over 50% of the patients so treated (*Lancet* 2:661, 1958). In one patient a neurogenic arthropathy was produced in a joint treated over a period of 18 months by monthly injections of hydrocortisone. The patient obtained almost complete relief of pain but at the expense of a functionless joint. Radiographs of the knees of 25 patients with rheumatoid arthritis were obtained before and after a course of treatment with hydrocortisone. Radiologic deterioration occurred in 13, despite clinical improvement in the majority. The authors believed that by a local mechanism in which functional improvement and relief from pain were the most important features, interference with the normal protective processes natural to inflammatory disease might have encouraged a degree of weight-bearing and mobility which was inherently traumatic. Dangerous progression of the disease under these circumstances might be expected.

Death due to Change of Anesthetic.—During a dental extraction a 6-year-old boy died from cardiac arrest. At the inquest the dentist stated that he first gave the boy nitrous oxide and then trichloroethylene. After three extractions the boy showed signs of returning consciousness and for five seconds ethyl chloride was administered while two more teeth were removed. Then the boy's respiration rapidly became shallow, and he collapsed and died in spite of attempts at resuscitation. Questioned by the coroner, the dentist said that he knew that there was some danger attached to giving trichloroethylene and ethyl chloride, but he did not think there was any risk in this particular case as the boy was strong and healthy. He agreed that it would have been safer to have used nitrous oxide alone. In his opinion the ethyl chloride caused the death. An anesthetist testified that the giving of trichloroethylene and ethyl chloride was widely practiced provided patients were not susceptible to a sudden change in anesthetics; trichloroethylene was dangerous for some patients; and ethyl chloride more so, particularly for young children. He thought that for dental extractions nitrous oxide was safer.

Malaria and Prematurity.—Cannon investigated the association of malarial infection and prematurity in Nigeria (*Brit, M. J.* 2:877, 1958). He studied 12,000 attendances by expectant mothers and 815 deliveries in hospital. The relationship between malarial infection of the placenta and the weight of the child at birth was determined in 392 single deliveries. The others were excluded, as the mothers had taken antimalarial drugs. Immediately after delivery of the placenta a wedge-shaped piece was cut from the maternal aspect of the placenta and a smear examined for malarial parasites. The infants were weighed and those weighing less than 2,500 Gm. (5.5 lb.) were classified as premature. Of 362 newborn babies, 30% had a placenta infected with malarial parasites, and the mean birth weight of those infected was 310 Gm. (11 oz.) less than those not infected. In deliveries where the placenta was found to be infected, 33% of the babies were premature, but in the deliveries in which the placenta was noninfected only 12% of infants were premature.

New Anticoagulant.—Results of clinical trials with a new anticoagulant, anisindione, are described by Kellaway (*Brit. M. J.* 2:889, 1958). In tests on volunteers it was found that a dose of 300 mg. of the drug given orally had an effect within six hours on the prothrombin time, lowering it to 50 to 70% of its normal value. Maximal lowering to within 10 to 20% of normal occurred within 24 hours in over half the subjects tested. Twenty-five patients with myocardial infarction, increasing coronary insufficiency, and deep venous thrombosis of the legs were given anisindione, starting with an initial dose of 200 mg. A satisfactory response, with prothrombin levels to within 10 to 20% of normal, was obtained in all patients. These levels were maintained by a daily maintenance dose of 25 to 350 mg. (average 100 mg.). The prothrombin level returned to normal within 36 to 72 hours of stopping treatment. No toxic side-effects were observed, and there was no evidence of hemorrhage or disturbed liver function. The anticoagulant effect of anisindione was rapidly reversed by vitamin K_1 in doses of 20 mg. orally and within four hours when the vitamin was given intravenously. Kellaway considered that anisindione has certain advantages over phenindione and the other anticoagulants in the speed and predictability of the initial response and the subsequent rapidity with which therapeutic blood levels of the drug can be obtained.

Asthma Treated by Hydrocortisone.—The condition of patients with bronchial asthma can be greatly improved by systemic treatment with corticosteroids, but large doses must be used, with the attendant risk of cortical atrophy and the usual side-effects. Continued treatment by this means must therefore be limited to patients whose life is endangered or in whom invalidism is threatened. Herxheimer and co-workers achieved a similar therapeutic effect by local instead of systemic treatment, using inhalations of hydrocortisone powder (*Brit. M. J.* 2:762, 1958). Patients were advised to inhale the contents of a capsule containing 15 mg. of micronized hydrocortisone snuff from a powder inhaler, half being inhaled in the morning and the remainder in the evening. The dose of 15 mg. was chosen on the assumption that only a small amount of this would be distributed systemically and would be below the body's own level of production of corticosteroids. Seventy-nine patients with chronic asthma, who had been observed for several years, were treated, and in 45 treatment was controlled with a placebo inhalation. In 33 of the 45 a definite improvement occurred, mainly in those asthmatics with evidence of allergic etiology and in those without hypersecretion. Improvement occurred in only 50% of the patients with infective cases. Patients with co-called "dry" asthma showed dramatic improvement. This treatment was of value in certain types of asthma.

Helm and Heyworth also concluded that inhalation of hydrocortisone acetate powder is an effective short-term treatment for some patients with bronchial asthma (*Brit. M. J.* 2:268, 1958). Rapid improvement occurred when they were changed from a placebo to hydrocortisone. Capsules containing 15 mg. of hydrocortisone acetate powder were used and patients instructed to adjust the number of inhalations to the response obtained. Half a capsule twice a day to three capsules daily were taken, most patients being maintained on one capsule a day. The assessment of the results was based on subjective and objective improvement. Of the patients in this series, 82% improved with the inhalations and 33% with the placebo. The difference is statistically significant. Little or no benefit was obtained in patients with chronic bronchitis treated by this method. In a longer-term trial in patients with recurrent acute asthma, the inhalations were effective in controlling the condition, but there was a strong tendency to relapse when the treatment was continuous. Better results were obtained when the inhalations were used intermittently for the attacks. The authors did not recommend this form of treatment in the dangerously ill patient. They estimated that a large portion (about 75%) of the inhaled hydrocortisone was absorbed, but even so the dosage was small compared with that used orally.

Nylon Alopecia.—A new type of traumatic alopecia was reported by Dr. Agnes Savill, who was consulted by a number of patients of both sexes because of falling hair without obvious cause (*Brit. J. Dermat.* 70:296, 1958). All gave a history of using hair brushes with nylon bristles. Examination showed that hairs had been pulled out by the roots or had been broken off and split longitudinally by these brushes. This finding is not unexpected from the very nature of nylon, which is tough, hard, and virtually indestructible. A substance that makes good pot-scourers could hardly be expected to be kind to the hair. Dr. Savill also blamed the shape of the ends of the nylon bristles, which are cut off square, instead of being rounded like hog bristles, and are therefore more traumatic. Recovery without treatment occurred in the patients when they ceased to use nylon brushes.

CORRESPONDENCE

RADIUM POISONING

To the Editor:—In the article "Where Are the Cases of Radium Poisoning," by S. D. Clark (*J. A. M. A.* 168:761-762 [Oct 11] 1958), spontaneous fractures, osteogenic sarcoma, and neoplasms of the paranasal sinuses are mentioned as signs of radium poisoning. Although brief mention is also made of roentgenological changes and trouble with teeth, the characteristic production of radiation osteitis and focal necrosis of teeth is of more than passing importance. Radiation osteitis has been found to affect the bone of the mandible and maxilla in a large proportion of the radium-dial workers I have examined. The findings on roentgenograms are similar to those of osteitis deformans (closely distributed areas of osteosclerosis interspersed with areas of osteoporosis). The alveolar processes of the jaw bones are affected more often than other bone because of their metabolic activity. Focal necrosis of the teeth also seen on roentgenological examination resembles dental caries, but the lesions are more sharply defined and occur on root surfaces below the gum line and under intact enamel. These two findings may be discovered on routine dental x-ray check-up and may be present long before any teeth are lost or long before fracture, sarcoma, or neoplasm supervene. These characteristic oral and dental lesions can be recognized easily by the alerted dentist and physician. The mottled osteitis and the dental focal necrosis are specific findings in this disease, and their presence may be regarded as pathognomonic (Dalitsch, *Fortnightly Rev. Chicago Dental Soc.* 18:5-7, 26 [July 15] 1949).

Walter Wm. Dalitsch, M.D.
30 N. Michigan Ave.
Chicago.

Dr. Dalitsch's letter was referred to Dr. Clark, and his reply follows.—Ed.

To the Editor: —Dr. Dalitsch is quite correct in emphasizing the dental changes that occur in radium poisoning and I agree that these characteristic areas of focal necrosis may appear long before any of the other lesions. The sclerotic changes mentioned in my article are considered to be part of the findings of radiation osteitis. Any support from the dentists would be most welcome. In an article directed toward dentists, the dental changes should be pointed out more specifically as Dr. Dalitsch has done in his letter.

TRAINING IN PEDIATRICS

To the Editor:—The address "Pediatrics in Transition," by Wheatley, in The Journal (168:856-859 [Oct. 18] 1958) is of interest. It is indeed commendable that some of the disciples of pediatrics should be yearning for new fields of interest, as a result of the accomplishments of their specialty and others in the field of preventive medicine.

I would like to offer an idea concerning postgraduate education which may fill a void in the lives of some of those charged with the job of "child health supervision." I suggest that pediatric residency training include experience in anesthesiology. In most areas of our country there is a shortage of physicians qualified in the administration of depressant drugs and the management of patients whose vital functions are depressed as the result of poisoning, infection, and trauma. A not inconsiderable number of surgical patients come from the pediatric age group. Certainly, the physician particularly trained in the psychology, physiology, and pathology of these patients could perform a needed service if he were trained in the applied pharmacology and physiology of the administration of the general depressants. He and others could serve their patient better at the head of the operating table than by assisting or observing on the other side of the ether screen.

Leo J. DeBacker, M.D.
State University of Iowa
Iowa City.

BACTERIAL ENDOCARDITIS DUE TO PSEUDOMONAS AERUGINOSA

To the Editor:—The report on a case of bacterial endocarditis due to Pseudomonas aeruginosa, by McDonald, Rhoads, and Knapp (*J. A. M. A.* 167:1490-1493 [July 19] 1958), is of great interest. We cannot subscribe, however, to the authors' opinion about the outcome being invariably fatal. In contradistinction to the 10 cases summarized in the paper, the treatment of which proved unsuccessful, though only two were observed after the advent of antibiotics, we had the opportunity to record a case in which there was full recovery (Gottsegen and Romoda, *Samml. seltener klin. Fälle* 13:115-120, 1957). Subacute endocarditis in a young man with rheumatic mitral stenosis and regurgitation began with a long period of freedom from bacteremia. Antibiotics (penicillin, streptomycin, and chloramphenicol) failed to show any effect on fever and hematuria. At last, blood and urine cultures became positive for Ps. aeruginosa; on the basis of favorable experiences in earlier cases with resistant germs, we decided to perform splenectomy. This was followed by spectacular recovery. No relapse has been observed in four years after the operation. The patient is working full time at present.

In a second case (unpublished) the portal of entry could not have been determined with certainty, for both purulent panophthalmitis and urethral dilatation preceded the bacterial endocarditis. Blood cultures, positive for Ps. aeruginosa, were obtained after enucleation of the diseased eye. Administration of polymyxin B led, however, to recovery without relapse for two years. Mitral regurgitation was the original valvular lesion in this case, too.

Neomycin was used with excellent result by Kenoyer and co-workers (*Am. J. Med.* 13:108 [July] 1952); however, their case is not strictly comparable to ours, since endocarditis of one week's duration after mitral surgery can be described only as acute. We conclude that the prognosis of this condition, the frequency of which is increasing in the present era of antibiotics, though serious, is not to be considered with undue pessimism.

CANCER SURVIVAL

To the Editor:—We are conducting a pilot study at the mental hygiene clinic of the Veterans Administration using motivational research techniques to determine why intelligent people (including physicians) do not have routine cancer checks. One factor which emerges is that "one out of four" is usually read, "one out of four others, not me!" The Public Education Review Committee of the American Cancer Society recommended in 1956 that primary emphasis be placed an annual health checkup examinations for adults, however well they may feel, and continued but secondary emphasis on danger signals. It has been observed that the society's three-legged stool—research, service, and education—has one decidedly short leg, and that short leg is education. We have evidence that some physicians give little or no support for the short leg. Unless we have routine cancer examinations we will continue to operate on late cancer. Every physician has a potential cancer detection unit in his own examination room—let him use it!

THE LEISURE CORNER

WOOD CARVING

For at least 5,000 years men have carved various objects, ornaments, and figures from wood. Wood carving as an art is mentioned in the Bible, and historical accounts from very early times tell of Egyptian and Grecian wood carvings. The earliest wood artifacts were probably the small masks and statuettes of gods and goddesses of African Negro tribes. The wood carvers of the Middle Ages helped to decorate the great cathedrals. One of the outstanding craftsmen was Grinling Gibbons (1648-1720), who carved the stalls of the Saint Paul's Cathedral in London. After the middle of the 1800's, wood carving attracted less interest. But in Switzerland wood carving is still a regular occupation. Today, fine wood carving is done by a number of American and European artists, and it has become an interesting hobby.

As a hobby, wood carving exerts a rewarding therapeutic effect, for there is an astonishing tonic quality to the feel of a chisel against a block of wood and in the contest between one's mastery of a tool and the wilfulness of its grain. Wood carving, for a time at least, can make the busy physician oblivious to his many medical responsibilities. But short notice is required for putting the hobby into action; the project at hand is clamped to a workbench, you pick up the chisel, and then go on from there.

One of the charms of wood carving—and this applies to most crafts followed as hobbies—is that there are no discouraging standards of perfection against which you must compete. What you do you do sheerly for your own approval, enjoying to the utmost your small triumphs and accomplishments. These invariably yield a sense of satisfaction out of all proportion to the results achieved. The reward comes not from being a professional wood carver but in bettering your own skill in wood carving as a hobby. Actually, wood carving brings delight and surprises all along the road from novice to expert. To succeed, one needs only a certain amount of spare time, an interest in the project undertaken, a few tools, patience, and the willingness to proceed. Any person who can sharpen a pencil can learn to carve wood.

Dexterity with tools is undoubtedly of great value; more important, however, is the discovery that it is possible to shape a rough piece of wood into any form desired. This is precisely the goal of the wood carver. In short, the purpose of carving wood is to make the surface more interesting by means of imposing a graceful pattern and inducing an intriguing play of light and shadow. In wood carving, certain obstacles have to be recognized, for example, the resistance and peculiarities of wood. The easiest woods for the wood carver to cut and finish are white pine, basswood, black walnut, and mahogany. There are other woods, of course, and these are beech, oak, holly, redwood, and sycamore. The wood should be well seasoned and possess a smooth texture and color. An accomplished wood carver will frequently use wood burls of knotted wood for an attractive surface pattern.

The exquisite wood carvings made during the Middle Ages were executed by means of crude tools. Today's hobbyists have available tools of the finest steel, highly finished, and in such a wide range of variety as to make a choice a simple matter. In general, wood carving need not require many tools. One or two very sharp knives and a sharp chisel will do for the beginner. A good wood carving knife is a tool of great utility, especially for making greater stop cuts deeper at one end than at the other. Chisels have straight cutting edges and are suited for cutting straight lines and carving flat planes; they are also useful for blocking out convex round projections, but they are not adapted for scooping out hollow curved forms. A penknife often makes the best tool for carving small objects. For larger pieces, a jackknife or hunting knife is required. The blades must be made of good steel and should be kept as sharp as a razor if good results are to be achieved. In addition, as the hobbyist progresses with wood carving, gauges are most useful, especially for cutting the various curvatures in outline and surface of a design. A dealer will furnish a chart showing the sweeps of various gauges, from which you can select the blade you want. Finally, although a scraper is highly important to a carpenter, it is useful in wood carving for removing rough surfaces and projections and for removing a design drawn on a piece of wood.

The novitiate wood carver should practice his strokes on a piece of soft wood about one-fourth to three-eighths of an inch in thickness. An outline of a simple design should be drawn on the surface of the wood; the figure then is carved out, stroke by stroke. The second piece may be of thicker wood, with the edges rounded off. After this, a simple figure can be carved in full. To do this, the hobbyist selects or cuts a block of wood according to the size needed. He draws a separate view of the figure on each side in outline, then he carves out the front and back and then the sides. Simple lines cut with single strokes are best. The sharp edges of the stroke are left to help show the planes of the figure.

Woods of all kinds have a fiber traversing their substance and a grain made of layers of annual growth. Cuts made at random are apt to split and splinter wood. To make a clean, precise shape, the carver should take out clean chips, and to accomplish this he must first sever the grain. If you watch a wood-chopper fell a tree, you will notice he scatters clean-cut chips, each one made by two strokes of his axe—the first horizontal and the second slanting downward. Similarly, if an expert whittler is observed, he, too, expends two cuts for every chip. Indeed, the wood-chopper and the whittler are applying basic rules of wood carving. In this connection, there are three basic rules: first, sever the grain of wood in the beginning, then cut out a clean chip; second, consider the grain of wood and make the slice (the second stroke) in a direction to bring the tool out clean, so that there is no splitting; and third, never place the left hand in front of a tool, for tools are sharp and they may split or slip through the wood, gashing the hand that is in the way. When working with a mallet, grab and guide the blade with the left hand, while striking with the right.

The question frequently arises in the mind of the beginner as to what to carve and how to obtain designs. The novitiate would do well to follow traditional methods at first, obtaining patterns that are established and modifying them to suit his own individual taste. It certainly is not necessary to purchase expensive pieces of lumber in the early stages of one's evolution as an expert wood carver. Every lumber yard has scraps of wood which can be bought very cheaply by the sackful. A no. 3 grade of wood is adequate, since it can be used for practice at first, and the number of knotholes present make little difference in the practice sessions.

During the earliest phases of your wood carving experiences you will frequently find yourself laughing at your own mistakes. But as you become proficient, you will soon find yourself completely absorbed in a hobby that will give you no end of pleasure. Soon, you will find considerable gratification in the results you obtain, and much joy in creating objects through your own dexterity.

BUSINESS PRACTICE

This is the eighth in a series of excerpts from the brochure on the Business Side of Medical Practice, prepared by the American Medical Association in cooperation with the Sears-Roebuck Foundation.

THE BUSINESS OF A PRACTICE

Though a physician is attracted to medicine because he likes to help people and is a humanitarian at heart, he soon realizes that to continue practicing he must charge and collect for his services. If he starts practicing with the right philosophies about money and with a sound system for handling the income from his practice, he learns to put the financial side of medicine into its proper perspective—in a secondary but important role.

How to Charge

A physician establishing practice has to decide what his charges for services will be. Burdened with the bills he incurred in setting up his office, it would be understandable if the doctor set out to make money fast. Such commercialism in the long run does not pay, for it affects the opinions that his patients, his colleagues, and the entire community develop about him. In fee-setting, his first question should be: "What is a fair fee?" Naturally, fees vary from community to community, and there is some differentiation between physicians in specialties.

The best way to find out what average fees are in a town is to check with the county medical society and with other physicians. Deciding what to charge involves weighing several factors: the fees charged by other doctors, the particular specialty and experience of the physician himself, and the cost of running his own office. He does not want to charge fees that are too high—nor does he want to charge too little. Fees that are too low do not win respect for a physician's services.

Years ago the medical profession followed the philosophy of charging the well-to-do patients higher fees to offset either low fees or free care for the poor. Today, because so many persons have a substantial part of their medical care costs paid for through insurance or some other mechanism, this philosophy is becoming a thing of the past. However, every physician is bound by his profession's code of ethics to provide medical care to anyone who needs it, regardless of cost, and a new physician accepts his responsibility for giving a certain amount of free services. Such care should be limited to those persons who for good reasons are financially unable to meet their medical bills. To those who can pay, the physician should make every attempt to charge a fair fee—and to give the best medical service possible per medical dollar.

Explaining Medical Costs.—When a patient understands what he is paying for and is satisfied with the services he received, the physician rarely has difficulty in obtaining his fee. Traditionally, the medical profession has shied away from discussing fees, feeling that the financial aspects of medicine were unpleasant and the less said, the better. But today, the American public is conditioned to itemized bills, regular billing, and budget plans for paying for goods and services. People expect doctors to adopt the same business principles in handling medical fees.

When a physician frankly discusses fees in advance with his patients, misconceptions about overcharging and fee frictions are minimized. A doctor or his patient may be reluctant to bring up the subject of fees. If the patient does not ask and a larger fee than expected is charged, it is advisable for the doctor to broach the subject. Telling a patient to "worry about the cost later" is not doing the patient a service. He wants to know approximately how much his surgery or treatment will cost so that he can plan or budget ahead for it. Several ways to encourage fee discussions are suggested for new physicians. A physician can display a fee discussion plaque, available for $1.00 from the A. M. A., which encourages talks about charges to achieve mutual understanding.

Keeping Track of Income and Expenditures

A physician, like any businessman, must be able to evaluate his own financial situation at any given time by checking his records. He has to know how much he has earned, how much he has collected, what he has spent, and what he owes. He should be able to compare this month's income with last month's, this year's with last year's, in order to evaluate his progress. Furthermore, the federal government requires increasingly deailed, complete financial records for income tax purposes. The doctor must not only keep a full record of what he earns but itemize his expenses so that he can explain them. He also must keep a number of government records for any employees he may have. For this reason he needs a good financial records system.

A doctor's bookekeeping system need not be complicated. Some of the most efficient systems are the simplest ones. No one system will meet the needs of every doctor. There are many excellent systems in use, and a physician establishing his own records system probably will want to talk over various possibilities with professional management advisers or others familiar with the medical bookkeeping field.

Elements of a Good Financial Records System.—Though the forms used may vary, there are four elements which should be a part of any good financial records system: (1) a daily listing of payments and charges, (2) individual records of patients' charges and payments, (3) a permanent ledger into which daily financial information is placed along with records of income and expenditures, with a detailed description of money disbursed, and (4) a petty cash system within the office for paying small bills from day to day.

Daily Record: In every office the doctor or his assistant must carefully record the names of every patient, the amount charged for medical service, and any money collected. This daily record, which sometimes is combined with a list of appointments for the day, when totaled at night should give the following information: the amount of cash collected, the amount of money received by check, and the amount charged to patients who have not paid and must be billed later. The total cash collected and the money received by check should be identical with the figures for these items shown on the day sheet.

Individual Patients' Records: Information regarding patients' charges and payments should be maintained in a separate file, which in bookkeeping jargon is termed the "accounts receivable records." This data, taken from the daily sheet, can be kept in a ledger or on account cards. It should not be placed on a patient's medical record, as the disadvantage of combining medical and financial records was pointed out earlier.

Patients' account records usually are quite simple, containing a column for entering the charge or fee for services, a column for entering the amount the patient has paid on account, and a column in which the balance appears. General information, including the patient's name, age, business and home address, and the name of the person responsible for the bill, usually also appears at the top of the card. (Often a child is the patient, but the parent is the individual responsible for the bill.)

In the process of transferring information about charges and payments from the daily record to the patient's individual record card, great care should be taken to make sure errors do not occur. Nothing irritates a patient more than to be billed for a service he paid for weeks before. The individual cards are used to make up the patients' bills at the end of each month, or at whatever interval the physician sends out statements.

Permanent Ledger: The daily sheet and the patients' individual financial cards are the working elements of a physician's bookkeeping system. These are used in keeping the permanent record of all income and expenditures. It is these permanent records which are used to analyze the doctor's financial status over a period of time, to compute his income tax, and to perpetuate his practice.

Some bookkeeping systems have forms similar to the daily record of patients' charges and payments on which the doctor or his aide keep track of disbursements. For example, if the doctor pays out two or three dollars for gasoline, this is listed, along with any expenditures for stationery, for medical supplies, or for paying routine office bills. These payments are listed and placed in proper columns, such as personal, maintenance, office expense, and so forth.

The totals from the daily record sheet and the totals from daily disbursement records are transferred to the permanent ledger each day, so that at the end of each month complete totals on all income and expenditures can be tallied. From this information a monthly statement of income, expenditures, net gain or loss, and other evaluating information can be prepared. Over a period of 12 months, this forms the basis for a yearly statement.

Typical items on the disbursement record include "expendables" (drugs, medical and laboratory supplies, office supplies); "maintenance" (rent, utilities, laundry, office upkeep); "capital outlay" (major equipment); "salaries"; "automobile"; "dues" (professional only); "subscriptions" (professional journals); "insurance" (medical or dental liability, office and equipment, fire and theft, Workmen's Compensation); "taxes" (from profession only); "entertainment" (minor donations, professional entertainment); "depreciation"; "bad debts"; and "collection fees" (paid out to agencies for fees). If a doctor receives any income from sources other than the practice of medicine, this should be listed as "personal" and itemized. Any expenses for living that he would incur regardless of his profession must be recorded as "personal."

Keeping accurate, detailed records pays off. It keeps the physician informed about his own financial picture and it simplifies preparation of tax and other necessary records. The establishment of a sound system and regular attention to that system is the most efficient means of handling these business details.

Petty Cash: Every office requires a little cash on hand to pay out for small items, but major bills should be paid by check. Usually $20 or $25 is ample to keep in the office for "petty cash" expenditures. Keep such funds in a safe place, preferably in a drawer that can be locked. In most offices an established sum is set up on a monthly basis and balanced each month. A small, triple-column account book should be kept with the petty cash in which debits or the amount paid, credit or the amount received, and the balance on hand can be indicated. No money should be taken out unless the amount and the reason for taking it along with the date are shown. Receipts or vouchers for each expenditure also can be used and are good business procedure. To replenish the petty cash, a check can be made out payable to petty cash and the money secured, preferably in small bills and change. This check should be made out for the amount actually spent, so that the petty cash fund returns to its original balance each time it is replenished.

Recording Money Obtained Out of the Office.—Sometimes a doctor is paid in cash or by check while he makes a house call or when he encounters a patient on the street. It is too easy to put the money in your pocket and forget about it. When the bills are made out, the payment has not been recorded and the patient receives a bill. This does not make for harmonious relations between doctor and patient. It is wise for a physician to carry a little booklet in his pocket so that when he makes house calls he can enter the name of the patient, charges and payments. This information then can be added to the daily sheet at the end of the day, and the money deposited as a part of the day's receipts. Don't use such payments as "spending money" or the records will never be straight.

General Bookkeeping Suggestions

The physician should maintain records on his personal affairs. These records include his property ledger in which he enters information about his personal property, real estate, securities, professional travel and other tax deductible expenses and honorariums. He will also want to set up separate files for listing his insurance and other personal financial information.

He must maintain banking accounts, and it is probably simpler to keep separate accounts for his practice and his personal affairs. All deposits from fees and all withdrawals for professional expenditures he handles through the professional account. Ideally, a deposit is made daily for each day's receipts with the deposit slip made up from the information on the day sheet.

The time will come when the physician will wish to consider placing his more valuable papers in a safe or safety deposit box. Records best kept in a safe include such vital documents as birth, marriage and divorce records, wills, passports, diplomas, business contracts, deeds or leases, investments and mortgages, property inventory lists, and insurance policies.

Other Filing Suggestions

In addition to medical and financial records, the physician must maintain a correspondence file into which all letters he receives and answers should go. He will decide himself whether to separate correspondence into another file or to place letters about patients' medical conditions with their medical records and letters regarding financial matters with financial records on patients. Whatever system he selects, he should set it up in an efficient manner, then adhere to the pattern established.

In all office filing systems, it is important to separate outdated material to avoid cramming of cabinets. A system for eliminating temporarily important information (letters of acknowledgment, duplicate forms and reports, and orders) should be established. In some offices, a "destruction date" is penciled at the top of the page on all correspondence routed to file and the cabinets regularly checked to eliminate outdated material. When destroying material which once was considered of permanent value, list each item on a single sheet, then have someone witness the destruction. This is proof of disposal in case your action later is questioned.

How Long Should Records Be Kept?—Legally, a physician's records belong to him and to his widow should he die. Thus, the physician has the legal right to destroy his records at any time. In general, professional records should be kept as long as they are of value to the patient in connection with his medical treatment and until the statute of limitations has run out on the various legal actions with which a physician might be faced.

Narcotics records, for example, must be kept a specified period of time under federal or state law —generally for two years. A record that may be useful as evidence in a pending criminal case should be preserved until the case is concluded. This same general rule also applies in civil court actions, in cases where disposition of a will or age of consent may be significant. That is why doctors usually preserve birth and death certificates and autopsy and police reports. Some doctors also arrange for disposition of patients' records in event of their death, usually by a colleague, to spare their widows this responsibility.

Rights to Records.—Though his records belong to him, a physician who moves his practice to a distant location may wish to provide his patients with x-ray interpretations or copies of other reports if they may be helpful in the future.

He need not give out medical records except when officially requested to do so by the proper law-enforcing bodies or when he is referring a case to a colleague for further treatment. In instances of referrals, the doctor decides whether to send the complete file on the patient or transmit only pertinent data, answering specific questions the other physician asks. The governing point is the welfare of the patient.

Remaining Personal Records.—Retention of personal records is a decision to be made by the physician himself. He must keep in mind the possibility that someday he may be questioned regarding a possible malpractice action. Consequently, he should keep professional reports beyond their apparent usefulness, to support his arguments and substantiate his claims should this someday become necessary. An attorney should be consulted concerning the period of time in which suit may be brought for malpractice or for breach of contract in the state in which the physician practices.

Stocks, bonds, titles, mortgages, contracts, insurance, and records bearing on income tax should be kept for at least three years. It is advisable to seek competent advice on such matters and request it in writing. Although the government does not normally indict for tax deficiencies more than three years after the questioned return is filed, it can bring suit at any time in a civil action to collect alleged back taxes, plus interest and penalties.

MEDICAL FILM REVIEWS

The Operating Microscope in Otologic Surgery: 16 mm., color, silent, showing time 23 minutes. Prepared in 1958 by George E. Shambaugh Jr., M.D., Eugene L. Derlacki, M.D., and Wiley H. Harrison, M.D., Chicago. Procurable on loan or purchase ($250) from George E. Shambaugh Jr., M.D., 55 E. Washington St., Chicago 2.

This film shows the most essential steps in the surgical technique of removing the epidermis from the tympanic membrane in preparation for application of a skin graft to repair a perforation or defect. The technique of this procedure is beautifully shown. Restoration of the articulation of the incus and stapes, in a case in which disarticulation had been accidentally done at a previous operation, is included. The hearing returned to normal after restoration. This is of value chiefly as a demonstration of unusual cause for hearing loss and its repair. The technique is not a standard one and is perhaps less important than the demonstration of the pathology. The technique of one method of preparation of the fenestra at the fenestration operation as devised by Lempert is shown. This is the most perfect demonstration of this technique that has yet been shown by motion pictures. The technique of the stapes mobilization in cases of otosclerotic ankylosis is very clearly demonstrated. This is also the best demonstration of technique that has yet been accomplished by motion pictures. All of these procedures are shown more clearly than is possible to demonstrate by direct visualization through the microscope. The film does not attempt to include detailed information such as diagnosis. Because of the excellence of the photography and visualization, this film is highly recommended for its teaching value to specialists who are either learning or doing these operative procedures.

Femoral Artery Bypass Graft with Crimped Teflon: 16 mm., color, sound, showing time 14 minutes. Prepared by W. Sterling Edwards, M.D., and Richard A. Dillard, M.D., Birmingham, Ala. Produced in 1958 by the Department of Surgery, Veterans Administration Hospital and Medical College of Alabama, Birmingham. Procurable on loan from Central Office Film Library, Veterans Administration, Washington 25, D. C.

The purpose of this film is to demonstrate the use of crimped Teflon prosthesis for a femoral bypass graft in a 71-year-old man who had had a left thigh amputation two years previously for gangrene of the left foot. It is a clearcut demonstration of the standard procedure of femoral bypass. The authors use a new experimental material, namely, crimped Teflon, but the advantages of this material over the existing ones are not mentioned. The narration is crisp and to the point. The photography is excellent and all irrelevant material has been deleted. The film should be useful for postgraduate teaching of surgical residents and surgeons interested in vascular surgery. If the exact indications of the procedure were outlined, the film might be useful for the general medical profession as a possible means of restoring peripheral arterial circulation.

Bence-Jones Protein Test: 16 mm., color, sound, showing time 5 minutes. Produced in 1957 by the Medical Illustration Service, Veterans Administration, West Side Hospital, Chicago. Procurable on loan from Veterans Administration, Central Office Film Library, Washington 25, D. C.

The purpose of this film is to demonstrate a positive Bence-Jones protein test. Although routinely performed in most clinical laboratories, the test is rarely positive. The film shows a dramatically positive Bence-Jones test applied to urine containing almost pure Bence-Jones albumose. It tells the story of this interesting phenomenon better and more convincingly than thousands of words would do. The pictorial demonstration of the changes as they occur when the temperature rises to the critical level and beyond must be revealing to the uninitiated and is fascinating even to the expert. Technically, the film is satisfactory and the narration is well done. It will be useful mainly in teaching medical technologists and medical students and is worth showing to physicians in general.

NEW FILM ADDED TO A. M. A. MOTION PICTURE LIBRARY

Intracranial Aneurysms: 16 mm., color, sound, showing time 43 minutes. Prepared in 1956 by Professor Rudolf Peter and Dr. Rudolf Malec, Prague, Czechoslovakia, for the Department of Popular and Scientific Films. Procurable on loan (service charge $3) from Motion Picture Library, American Medical Association, 535 N. Dearborn St., Chicago 10.

This film on the surgical treatment of intracranial aneurysms presents the anatomic and pathological background of these lesions and shows the technique employed in their diagnosis, evaluation, and subsequent surgical treatment. The subject is based on an experience of about six years with 48 patients. Examples of the surgical treatment of intracranial arteriovenous malformations are included also. This is a beautifully dramatic and scientifically correct presentation of a subject on which the authors are authorities. The animation is exceedingly good. The film is especially recommended for residents, medical students, and general surgeons. It would also be of interest to neurosurgeons because of the special instruments and the statistics presented.

MEDICAL LITERATURE ABSTRACTS

SURGERY

Superior Vena Caval Obstruction. R. Allansmith and V. Richards. Am. J. Surg. 96:353-359 (Sept.) 1958 [New York].

The work done in the experimental laboratory has increased our knowledge of the clinical picture associated with superior vena caval obstruction. The increased venous pressure causes dilation of the veins over the upper half of the body. There is respiratory distress, increased by the edema of the neck and glottis, plus pleural effusions, as well as by the increase in the carbon dioxide content of the blood in the respiratory center. Headache and somnolence are caused by congestion of the brain, and there may be syncope and even Jacksonian convulsions from cerebral thrombosis. The cerebrospinal fluid pressure is elevated. The eyes bulge, and the lids are edematous. All the symptoms of this condition are exaggerated by bending forward, and many patients sleep sitting up, since they become dyspneic with recumbency.

Roentgenologic examination usually reveals a widened mediastinal shadow. A tumor or aneurysm may be obvious with the use of routine films, or tomograms may be required to visualize a mass. Phlebograms usually reveal a maze of collateral vessels and a block at the thoracic outlet. If the obstruction includes the azygos vein, and it usually does, the blood flow in the remainder of the azygos system and in the superficial and deep collateral veins, carrying blood to the femoral and iliac veins or to other veins communicating with the inferior vena cava, is prominent in a caudal direction. In the few instances in which the occlusion is above the azygos vein, a prominent venous plexus develops over the sternum, seeking the perforating branches of the internal mammary vein and thence to the azygos veins via the intercostals. If the superior vena cava is occluded below the azygos vein, or if both the superior vena cava and the azygos systems are obstructed, the blood from the upper half of the body must take a very circuitous route in order to return to the heart through the inferior vena cava. Venous pressure increases with exercise if a block is present, whereas elevated venous pressures caused by heart failure do not show a significant increase with exercise. If a tourniquet is applied to the chest, constricting the superficial thoracoabdominal vessels, and the venous pressure rises with inspiration, the block is distal to the azygos vein.

The prognosis depends upon: (1) the cause of the obstruction; (2) the location and rate of obstruction; and (3) the adequacy of the collateral circulation which develops. Mediastinal tumor is still the single most common causative factor. The over-all mortality from severe obstructions is approximately 70 to 80%, regardless of cause. The nonsurgical treatment includes the use of antibiotics, chemotherapy, and x-ray therapy, while the surgical treatment consists of phlebotomy, mediastinal decompression, and vascular grafting. In the series presented, 21 patients have had almost immediate relief of symptoms after surgical procedures designed to relieve the obstruction and establish an adequate shunt. Arterial homografts (preserved) were used in 10 patients, arterial heterografts (preserved) in 1, vein autografts in 7, and prostheses (crimped nylon) in 1; no grafts were employed in the remaining 2 patients. The right auricular appendage was the site of the shunt to the heart in 10 patients, and the superior vena cava in 8. At the present time the optimal treatment of superior vena caval obstruction, not due to a malignant neoplasm but to a benign fibrotic process, is the insertion of a homograft between the proximal patent caval or innominate veins and the intrapericardial superior vena cava, if patent, or the right auricle.

The Pathogenesis and Treatment of Primary Hydroceles in Infancy and Childhood. D. G. McKay, R. Fowler Jr., and J. S. Barnett. Australian & New Zealand J. Surg. 28:1-11 (Aug.) 1958 [Melbourne].

The authors report on 100 infants and children with hydrocele who were treated at 2 children's hospitals in Melbourne and Adelaide, Australia. A wide anatomic variety of the hydrocele sac was observed, with all intervening gradations between the simplest communicating type of sac and the

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1949 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

most complex noncommunicating and multiple saccular formations. Whether communicating or noncommunicating, such hydroceles were always associated with an abnormal patency of at least the proximal part of the processus vaginalis testis. From the succession of types observed, the natural history of evolution of the various forms was considered as beginning with simple patency of the vaginal process and its gradual distention by peritoneal fluid. If delayed spontaneous obliteration of the entire vaginal process should occur, then spontaneous cure will result and the fluid will be reabsorbed. But if a fine vaginal process should become obliterated only at its junction with the hydrocele, the next evolutionary change would be the dilatation of that portion of the process immediately above the distal sac. When the communicating process is wide and has a communication with a distal sac, progressive enlargement of the hydrocele might take place upwards into the cavity of the hernial sac above, producing a rather bizarre "inner sleeve" arrangement which had not been reported before.

These findings suggested the concept of a congenital origin of the hydrocele, and this concept was supported by additional evidence. The right-sided preponderance, typical of hernias and undescended testes, was likewise found for these hydroceles. A history was usually elicited, even in the apparently noncommunicating cases, of intermittent variation in the size of the hydrocele at some stage in its life history. The fluid from both communicating and noncommunicating hydroceles was microscopically and chemically indistinguishable from peritoneal fluid. Surgical treatment, therefore, was directed to the vaginal process alone. Simple herniotomy with transfixion, ligation, and division of any patent derivative or strand of the vaginal process was performed. The hydrocele was emptied by simple aspiration or minimal stab incision. Imprisoned hydrocele fluid was shown to be reabsorbed from both communicating and noncommunicating hydroceles after simple operative ablation of a patent funicular process. If the hydrocele sac was left behind, emptied of its fluid, reaccumulation of such hydrocele fluid did not occur after severance of the funicular process or strand. Of the 100 children operated on, 6 had had recurrences after previous orthodox surgery; these recurrences were always associated with a fine patent vaginal process which had been overlooked at the original operation. Severance of this fine process cured the condition. The more extensive interference with the hydrocele sac inherent in orthodox surgical procedures is therefore unnecessary. In infants, the management of hydroceles should be expectant because of the tendency to spontaneous cure.

NEUROLOGY & PSYCHIATRY

The Uveo-Encephalitic Syndrome or Vogt-Koyanagi-Harada Disease. H. Reed, A. Lindsay, J. L. Silversides and others. Canad. M. A. J. 79:451-459 (Sept. 15) 1958 [Toronto].

The uveo-encephalitic syndrome is characterized by uveitis, depigmentation of skin and hair, and cerebral manifestations. It has long been recognized by ophthalmologists, but it may present a diagnostic problem to general physicians, neurologists, neurosurgeons, and dermatologists. The authors review the literature, report 5 more cases, and discuss the etiology of the condition. Although Vogt is usually given credit for being the first to describe this syndrome in 1906, it was described by Hutchinson in 1892. Koyanagi wrote an account of this disease in 1929, reviewing 12 cases from the literature and presenting 4 of his own. He described the clinical picture of headache, fever, bilateral uveitis, dysacousia, vitiligo, poliosis, and alopecia. After Koyanagi's publication the condition was known as the Vogt-Koyanagi disease. In 1926 Harada described 5 cases characterized by bilateral posterior uveitis with inferior exudative retinal detachments. For nearly two decades it was considered that the Vogt-Koyanagi disease and the Harada disease were 2 separate entities, the difference being that in the former the uveitis was anterior in situation and no detachment occurred, while in the latter the uveitis was posterior and was accompanied by retinal detachment; but this distinction is not justified.

Great variations in the severity of the clinical picture may occur, and incomplete manifestations of the disease are probably common. It has been pointed out that bilateral uveitis with pleocytosis of the cerebrospinal fluid is not uncommon and that such cases should probably be considered as "formes frustes" of this disease. The 5 cases presented here show the great variations in severity and in the clinical picture which may be encountered. The first patient exhibited mild manifestations of the disease. The second patient had retinal detachment in one eye only. His case was unusual in that a severe encephalitis developed, which resulted in diabetes insipidus and a permanent psychosis. The third patient had a condition typical of the picture described by Harada with bilateral retinal detachments. The fourth patient illustrates an unusual mode of onset because recurrent uveitis preceded the neurological signs. It is interesting that, whereas the ocular manifestations failed to respond to corticosteroids, the neurological lesions rapidly responded to a dose of Meticorten which was more than double the previous dose. In the fifth patient the disorder presented as a bilateral retrobulbar neuritis and then developed into an apparently typical Harada pattern with recovery. Two theories concerning the cause of this disease have been advanced, namely, that it is (1) a virus infection and (2) an allergy to uveal pigment. At the present time the weight of evidence suggests a virus as being the cause. No effective treatment is known, except that some reports suggest that corticosteroids might be of value. Wider recognition of the disease is important, so that unnecessary craniotomies will be avoided, because severe cases may resemble a rapidly expanding intracranial space-occupying lesion.

Deficiency of Vitamin B-Complex Causing Psychiatric Symptoms of Atypical Endogenous Depression. E. J. W. Keuter. Nederl. tijdschr. geneesk. 102:1501-1503 (Aug. 2) 1958 (In Dutch) [Amsterdam].

The author presents the history of a 40-year-old woman who was referred to a psychiatric clinic because of severe depression. Pernicious anemia was thought of, because the diameter of the erythrocytes was enlarged, and achylia gastrica was detected, but sternal puncture did not corroborate this diagnosis. Since the patient also had hypochromia, she was treated with iron and hydrochloric acid. The psychiatric picture, which had existed for 17 years, remained uninfluenced by electroshock and chlorpromazine treatments. Later, a pellagra-like syndrome was recognized, and it was found that the vitamin B_1 content of the blood was low. The administration of vitamin B complex caused disappearance of psychiatric symptoms, so that the patient could be discharged from the clinic.

GYNECOLOGY & OBSTETRICS

Myopathy of the Climacteric (Menopausal Muscular Dystrophy). H. E. Kaeser. Schweiz. med. Wchnschr. 88:849-855 (Aug. 30) 1958 (In German) [Basel, Switzerland].

The author groups the climacteric or menopausal form of muscular dystrophy with the degenerative myopathies, which presumably are caused by metabolic or endocrine disturbances, although the relationship has not been definitely established. In a survey tabulation of myopathies and myositides, 3 main groups are differentiated: (1) hereditary forms; (2) myopathies resulting from metabolic disturbances; and (3) chronic myositides. The second group, in which the author includes menopausal muscular dystrophy, also embraces the myopathies that accompany the following disorders: hyperthyroidism, hypothyroidism, liver diseases, pancreatic and adrenocortical insufficiencies, and vitamin E deficiencies.

The author presents 3 established and 2 doubtful cases of climacteric myopathy. He points out that, after early reports by Nevin and Bramwell in 1936 and 1922, respectively, Shy and McEachern i 1950 and 1951 presented several papers on a disorder which they designated as "menopausal muscular dystrophy." The disorder is characterized b weakness in the musculature of the pelvic an shoulder girdles; it occurs chiefly in women durin and after the menopause. Muscular atrophy is no always evident, because the muscles are covered b fat tissue. The involved muscles are soft, the dee reflexes are normal in the early stages, but late they become weaker or completely abolished. Th weakness appears first in the muscles of the pelvi girdle and later in a milder degree in those of th shoulder girdle. The women usually complain of increasing weakness while walking. When ascendin the stairs, they have to pull themselves up b grasping the handrail. They cannot rise from chair without aid, they fall without apparent reason, and later, when the arms become involve they need help in dressing themselves. Other peopl notice the waddling walk and the increasing helplessness.

On biopsy, in the series examined, the muscle were pale. Histological examination showed spott degeneration of the muscle fibers. Endocrine disorders could not be established. Electromyographi and transaminase studies were made. During th active phase of the myopathy the glutamic-oxaloacetic transaminase was increased. With the administration of prednisone an impressive and lasting clinical improvement could be observed in of 4 patients, with normalization of the transaminase. There is no evidence as to whether menopausal muscular dystrophy is related to a myopath or a chronic polymyositis.

Meigs's Syndrome. P. Stavem. Tidsskr. norske læg for. 78:703-704 (Aug. 1) 1958 (In Norwegian) [Oslo

In most cases of Meigs's syndrome the pelvi tumor is the size of a child's head or larger, bu tumors smaller than a hen's egg have been see According to Meigs, the term Meigs's syndrom should be used only in cases in which the tum consists mainly of fibrous tissue, as ascites an hydrothorax are fairly frequent only in fibrous ovarian tumors. Sometimes there is marked hydrothora which reaccumulates rapidly after tapping, whil ascites is scanty and established on laparotom The fluid in the pleural cavity is like that in th peritoneal cavity and is usually a transudat though sometimes an exudate is found, with protei content of more than 3% and positive Rivalta tes In case of rapidly reaccumulating hydrothorax an pelvic tumor in a woman of any age, the possibilit of Meigs's syndrome should be considered. All th symptoms will disappear as by magic on remov of the tumor. Meigs's syndrome is not to be excluded because ascites cannot be demonstrated clinically or because ascites and pleural fluid resemble an exudate more than a transudate. A large, firm ovarian tumor may occasionally be mistaken for a fibromyoma of the uterus. In the case reported, in a woman, aged 37 years, admitted with a right-sided pleural effusion, there was rapid reaccumulation after tapping. The effusion disappeared within 2 weeks after removal of a large fibroma of the ovary.

Preservation of Ovarian Function in Combined Treatment of Early Cancer of the Cervix Uteri in Young Women. C. Krebs and N. Blixenkrone-Møller. Ugesk. læger 120:1012-1015 (July 31) 1958 (In Danish) [Copenhagen].

At the Radium Station in Aarhus during the one-year period 1949-1950, an attempt was made to prevent the grave complications of premature climacteric due to irradiation in young women with cancer of the neck of the uterus in early stage by lifting one ovary or both ovaries to a distance of at least 12 cm. from the tumor before radium treatment. Six of the 8 patients who received only radium treatment after the intervention have preserved ovarian function. The material seems to show (1) that neither lifting of the ovaries as such nor preserved ovarian function has any adverse effect on the result of radium treatment of cancer of the neck of the uterus, (2) that it is not possible by the operation to attain preserved ovarian function if combined radium-roentgen-ray treatment is applied, and (3) that after the intervention most of the patients given only radium treatment preserve their ovarian function. The authors intend to resume this method of treatment in patients under 40 years of age with cancer of the neck of the uterus in stages 1 and 2. If laparotomy shows the disease to be more advanced than indicated by the clinical examination, the intended intervention must be given up, as in such cases intensive radium-roentgen-ray treatment is necessary.

Precordial Murmurs During Pregnancy and Lactation. J. W. Hurst, J. Staton and D. Hubbard. New England J. Med. 259:515-517 (Sept. 11) 1958 [Boston].

A variety of innocent murmurs may develop during pregnancy and are often attributed to heart disease. Some of these murmurs are due to an increase in blood velocity and emanate from the heart itself, whereas others are of extracardiac origin. The precordial murmur in one patient was due to a bruit in a branch of the mammary artery; it persisted after delivery and vanished only upon termination of lactation. The precordial continuous murmur in a second patient originated in the large dilated veins of the breast and could be altered by firm pressure with the stethoscope bell, indicating that the murmur was extracardiac in origin and suggesting that it was related to the vascular engorgement of the breast that occurs during pregnancy.

The Prophylaxis of Iron-Deficiency Anaemia in Pregnancy, D. N. S. Kerr and S. Davidson, Lancet 2:483-488 (Sept. 6) 1958 [London].

The authors studied patients attending the antenatal clinic of the Simpson Memorial Maternity Pavilion in Edinburgh in an attempt to ascertain the incidence of anemia in pregnancy; the effect of season, age, parity, recent pregnancy, and duration of pregnancy on the incidence and degree of anemia; the adequacy of the present diet of Edinburgh mothers; the most suitable forms of iron to be administered orally, if supplements are necessary; and the stage in pregnancy at which iron supplements should be started. It was found that, although severe anemia is rare at the beginning of pregnancy, mild anemia with a hemoglobin level of less than 12.6 Gm. per 100 cc. (or 85%) is common. No correlation was found between incidence of anemia and age, parity, or number of pregnancies within the previous 5 years. An estimate of the average daily dietary intake of iron in pregnant women in Edinburgh suggested that it is slightly less than the 15 mg. usually recommended. The incidence or degree of anemia was not found to correspond closely with the dietary intake of iron.

To obtain information about the potency and toxicity of certain iron preparations, an investigation was undertaken on women attending the antenatal clinic. The 430 women accepted for this investigation were assigned by random selection (choosing a card from a pack) to one of 4 groups. Group A (20%) received ferrous sulfate; group B (20%) received ferrous gluconate; group C (20%) received ferrous gluconate plus ascorbic acid; and group D (40%) formed the control group which received pills containing lactose. As regards gastrointestinal side-effects, no difference was found between ferrous sulfate and ferrous gluconate, given in doses containing 105 mg. of iron daily. Neither preparation caused significantly more unpleasant gastrointestinal symptoms than the other or than the control pills containing lactose. The addition of ascorbic acid to ferrous-gluconate pills did not increase their therapeutic efficacy or reduce their toxic effects. The authors suggest the following scheme of supervision for antenatal patients: routine hemoglobin estimation at the first antenatal visit; iron therapy from the first visit for all patients with an initial hemoglobin level of less than 12.6 Gm. per 100 cc. (85%); and routine administration of elemental iron in a dosage of at least 105 mg. daily to all patients from the 24th week to term. This dosage is provided by one 300-mg. (5-grain) pill of ferrous gluconate 3 times a day. The customary dose of ferrous sulfate is one 180-mg. (3-grain) pill 3 times a day, which provides a much greater amount of elemental iron, namely, 180 mg. per day. The choice of preparation for iron therapy remains controversial. This study suggests that ferrous gluconate may be slightly more efficient than ferrous sulfate (when given in the same dosage in terms of elemental iron—namely, 105 mg. daily).

A Report of 549 Cases of Breast Cancer in Women 35 Years of Age or Younger. N. Treves and A. I. Holleb. Surg. Gynec. & Obst. 107:271-283 (Sept.) 1958 [Chicago].

Five hundred forty-nine women, aged 35 years or less, with cancer of the breast were studied at the Memorial Center for Cancer and Allied Diseases in New York from 1937 through 1949; sarcomas were excluded. Twenty-one patients were between the ages of 19 and 25 years, 124 between 26 and 30 years, and 404 between 31 and 35 years. Eighty-two per cent of the patients were married; and 66% had been pregnant at least once. The incidence of previous gynecologic surgery was only 5.2%, but additional gynecologic disorders were found. Nipple discharge was present in 5.5%, and bloody discharge outnumbered serous discharge. Infiltrating duct carcinoma accounted for 86.6% of the pathological diagnoses. The minimum 5-year clinical cure rate was 30.7%, if all patients other than those known to be free of clinical evidence of recurrent or metastatic cancer 5 years after therapy were classified as failures. The 5-year clinical cure rate in terms of operability was 37.7%. If further selection were made in the group with operable disease, a maximum cure rate of 40.6% could be obtained. These data and a review of the literature indicate that carcinoma of the breast in young women offers a prognosis equal to that in older women.

When axillary lymph node involvement was present, the clinical cure rate was lower than that found in older women, suggesting that the disease may be more lethal in the young patient when regional metastases have occurred. Outer quadrant lesions showed a higher frequency of axillary node metastases than those arising in the inner quadrants; yet, the 5-year clinical cure rate was essentially the same, whether the tumor was located in the inner or the outer half of the breast. When axillary nodes were not involved, cancers located in the outer half of the breast had an 8% better clinical cure rate, compared with the rate for inner half, midline, and central lesions combined. The prognosis was better for patients with the less common type of cancer of the breast, e. g., medullary, comedo, and colloid carcinoma, than for infiltrating duct carcinoma. The incidence of axillary node metastasis was likewise lower. Infiltrating duct carcinoma, grade 2, showed a lower incidence of axillary node metastases and a higher clinical cure rate than grade 3. The higher the level of axillary node involvement, the poorer was the prognosis. Involvement of level 3, however, should not be used as a criterion of inoperability, since 16% of these patients were free of recurrent cancer 5 years or more after radical mastectomy.

Although pregnancy occurring simultaneously with breast cancer had an extremely poor prognosis, the pregnancy should not be utilized as a criterion of inoperability. Pregnancy occurring subsequent to surgical therapy for cancer of the breast appeared to have little influence on prognosis. Definite conclusions concerning the management of pregnancy for women with concurrent cancer of the breast could not be formulated. Likewise, no recommendations could be made regarding management of pregnancy for the woman previously treated for breast cancer. Patients who delayed longer than 6 months before surgical treatment showed a higher incidence of axillary node metastases and a lower clinical cure rate than patients who sought medical care earlier. Postoperative x-ray therapy, regardless of axillary node involvement, had no influence on the clinical cure rates.

Patients considered clinical failures had a median survival of slightly over 2 years. More than two-thirds had died by the end of the third year. There was no postoperative mortality in 399 patients treated by radical mastectomy. When the axillary lymph nodes were uninvolved, prophylactic castration did not affect the clinical cure rates. When the axillary nodes were involved, the 5-year clinical cure rate was 8.3% higher in patients who were castrated. The median survival after therapeutic castration for metastatic cancer of the breast was 9 months. Prophylactic simple mastectomy is not to be recommended even in the presence of a significant familial history of cancer of the breast. The incidence of axillary node metastasis increased proportionately with the size of the tumor. The 5-year cure rate diminished as the size of the tumor increased. Tumor size alone was of significant prognostic import, whether the axillary nodes were involved or not.

These data suggest that certain criteria of operability should be modified. Even young women with axillary node metastases at the highest level have a 16% chance for 5-year clinical cure. Early diagnosis and prompt radical surgery offer the best chance for survival. The maximum opportunity for 5-year clinical cure exists when the primary lesion is small and still localized to the breast. Tumors occurring in the breast during pregnancy should be treated immediately. The previous impressions of poor prognosis for breast cancer in the young woman who is not concurrently pregnant must be supplanted by a more hopeful outlook.

PEDIATRICS

Serious Coxsackie Infection in Infants and Children: Myocarditis, Meningoencephalitis, and Hepatitis. D. M. Hosier and W. A. Newton Jr. A. M. A. J. Dis. Child. 96:251-267 (Sept.) 1958 [Chicago].

There is increasing evidence to show that Coxsackie virus, group B, may cause fatal myocarditis in the neonatal period. This prompted the authors to report on the isolation, during a nonepidemic period, of a Coxsackie, group B, virus in 2 male infants, a female infant, and a 5-year-old boy admitted to hospital in the last 2 years. The 7-week-old boy died of heart failure after a 10-day illness. The autopsy findings consisted of a severe necrotizing inflammation of the myocardium and evidences of cardiac failure elsewhere in the body. Coxsackie virus, group B, type 4, was isolated from the myocardium. A blood culture yielded no growth. The 8-day-old girl was hospitalized with a diagnosis of sepsis showing jaundice and lethargy. A progressive cardiac lesion and a bleeding tendency developed, and the patient died after an illness of about 9 days. Postmortem examination showed extensive focal necrosis of the heart and liver, a mild meningoencephalitis, and focal necrotizing infection of the adrenal. Coxsackie virus, group B, type 4, was isolated from the heart, liver, kidney, and lung. No virus isolation studies were performed on the 6-day-old boy who died on the day of admission. The infant's mother was incubating pleurodynia at the time of delivery and developed the typical clinical findings 24 hours post partum. The infant's myocardium showed no morphologic changes, but diffuse meningoencephalitis, severe focal hepatic necrosis, necrosis of the entire fetal cortex of the adrenal, and focal necrosis of the bone marrow were found at autopsy. It was postulated that the brain and liver changes were produced by a Coxsackie, group B, virus infection. The 5-year-old boy recovered from myocarditis, during the acute phase of which a Coxsackie virus, group B, type 2, was isolated from the stool, and a subsequent rise in homologous serum neutralizing antibodies was demonstrated. Treatment with digitalis and cortisone produced improvement, although cardiac enlargement persisted for 10 months. The patient recovered completely.

According to the literature, the predominant finding in isolated myocarditis has been interstitial inflammation, while necrosis of muscle fibers seemed to predominate in virus myocarditis. These findings induced the authors to review their own observations made between 1951 and 1957 at autopsy on 9 infants and children with myocarditis of varying severity. All but 2 of these patients died during the summer months. The degree of cellular infiltration paralleled the amount of myocardial necrosis in all but one patient. The brain and the liver showed a significant incidence of pathological changes in these children with myocarditis. Four of the 9 showed a mild to severe meningoencephalitis, and 4 had moderate to severe hepatic necrosis, with little or no cellular reaction. The distribution of the necrosis was centrilobular in most, but some showed an irregular pattern of focal necrosis. It is of interest to note, however, that the children who showed the hepatic changes had only mild to moderate changes in the myocardium, while those showing marked myocardial damage showed no liver damage histologically.

Acute Cerebellar Ataxia of Undetermined Origin in Childhood. D. N. Walcher and A. T. Ross. A. M. A. J. Dis. Child. 96:278-283 (Sept.) 1958 [Chicago].

The authors call direct attention to a syndrome of acute cerebellar ataxia which, as a rule, carries an excellent prognosis. Twenty patients with acute cerebellar ataxia, unassociated with any definite cause, 17 of whom were between the ages of 9 months and 4 years and 3 were aged 7 or 8 years, were seen at the Indiana University Medical Center and the Indianapolis General Hospital between 1948 and 1957. Premonitory symptoms of listlessness, drowsiness, fever, vomiting, headache, or a cold were present in 13 children and preceded the ataxia by one or several days. The main feature was the rapid development of ataxia, which always affected the trunk and legs and in some children the arms as well. No abnormalities were detected in the ocular fundi. The hyporeflexia often seen in cerebellar lesions was common. Neurological examination disclosed no clinical evidence of involvement of structures other than the cerebellum. The average period for complete recovery was 5 weeks. As a rule, the children had a single episode of ataxia, but 2 of them had relapses.

It appears that this disease provokes little systemic response to whatever may be the causative agent, a fact in keeping with its benign course. The cause of the disease is undetermined, but it is presumably a viral infection. Tumor of the posterior fossa, acute labyrinthitis, encephalitis, drug intoxication, and hysteria are the most important conditions for which differential diagnosis is required.

Oral Phenoxymethyl Penicillin Therapy in Prophylaxis of Recurrent Rheumatic Fever. S. Kaplan. A. M. A. J. Dis. Child. 96:288-293 (Sept.) 1958 [Chicago].

The author reports the results in a group of 266 patients in whom oral administration of phenoxymethyl penicillin (penicillin V) had been used exclusively as a prophylaxis against recurrences of acute rheumatic fever. All the patients studied had had at least one previous episode of acute rheumatic fever. Throughout the period of study they were treated with one oral dose of phenoxymethyl penicillin, 125 mg. (or 200,000 units) daily. In the event of an intercurrent acute streptococcic infection, the amount of phenoxymethyl penicillin given was increased to 625 mg. (1 million units), administered in divided doses daily for a period of 10 days. There were no instances of toxic effects due to the oral administration of phenoxymethyl penicillin.

There was a recurrence of acute rheumatic fever among only 6 (2.2%) of the 266 patients studied. Three of these patients had had at least 3 episodes of acute rheumatic fever prior to the institution of penicillin phophylaxis. A 4th patient had a recurrence of acute rheumatic fever while still being given steroid therapy. It is possible that the 4 patients were still in an active subclinical phase of rheumatic fever when a clinical recurrence became manifest. One episode of subacute bacterial endocarditis due to a streptococcus organism of the viridans group occurred during the period of penicillin prophylaxis. This infection was cured by larger oral doses of phenoxymethyl penicillin. The low incidence of recurrence of rheumatic fever and intercurrent infection due to beta-hemolytic streptococci, group A, indicates that this form of prophylaxis is practical and successful.

Chronic Renal Disease in Children: Correlation of Clinical Findings with Morphologic Characteristics Seen by Light and Electron Microscopy. L. R. Vernier, M. G. Farquhar, J. G. Brunson, and R. A. Good. A. M. A. J. Dis. Child. 96:306-343 (Sept.) 1958 [Chicago].

The authors report a study on 72 kidney biopsy specimens from 58 children with diffuse renal disease. Included were children suffering from anaphylactoid purpura, disseminated lupus erythematosus, acute, subacute, and chronic glomerulonephritis, and the nephrotic syndrome. Needle biopsy of the kidney was found to be a safe, relatively atraumatic procedure in children, worthy of extensive use as an investigative technique. Light microscopy revealed the renal lesion of anaphylactoid purpura to be segmental glomerulitis characterized by occlusion of lobules of the glomeruli by fibrinoid material. The glomerular lesion observed in anaphylactoid purpura is similar to an abnormality often seen in disseminated lupus erythematosus, and it is suggested that anaphylactoid purpura probably should be classified as a systemic fibrinoid vascular disease.

The characteristic pathological abnormalities observed in kidney biopsy specimens from children with disseminated lupus erythematosus varied from segmental vascular fibrinoid lesions to severe glomerulonephritis. Serial biopsies in 3 children treated with intensive prolonged corticosteroid therapy confirmed the clinical and laboratory evidence of improvement in renal disease during the interval of treatment. Renal biopsy may occasionally aid in the confirmation of the diagnosis of disseminated lupus erythematosus when other evidence is inconclusive.

Biopsy findings in the patients with glomerulonephritis, including acute, subacute, and chronic cases, supported the concept that acute streptococcic nephritis is an entity separate from subacute or chronic glomerulonephritis. The pathological findings obtained by kidney biopsies in patients with the nephrotic syndrome are correlated with the clinical and laboratory features of the disease It is concluded that the pathology of nephrosis is related to the duration and the severity of the disease.

Electron microscopic observations of 42 rena biopsy specimens from children with glomerulonephritis, the nephrotic syndrome, and disseminated lupus erythematosus revealed glomerula changes. The 3 distinct components of the glomerular capillary wall—endothelium, lamina densa and epithelium—appear to be differently involve early in the course of each of these diseases. Th principal glomerular abnormality observed in the nephrotic syndrome and the only abnormality seen in early or "pure" nephrosis are a marked loss or smudging of epithelial-cell foot processes. Abnormalities of the foot processes have not been seen as an early manifestation in patients with anaphylactoid purpura, glomerulonephritis, or disseminated lupus erythematosus.

Electron microscopy of glomeruli from patients with glomerulonephritis revealed pronounced proliferation of endothelial cells, some proliferation of epithelial cells, and an accumulation of basement-membrane-like material. Early in the course of glomerulonephritis, the epithelial-cell foot processes appeared normal. In the subacute and chronic forms of glomerulonephritis, severer degrees of basement membrane proliferation were observed. Electron microscopy of kidney biopsy specimens obtained early in the clinical course of acute disseminated lupus erythematosus revealed basement membrane thickening and variable degrees of endothelial proliferation. The severity of the basement membrane involvement in disseminated lupus erythematosus seems to be related to the duration of the disease process. Abnormalities of the epithelial cells were encountered only late in the course of the disease.

Repeated Follow-up on Fate of 298 Asthmatic Children. E. Ryssing. Ugesk. læger 120:1052-1056 (Aug. 7) 1958 (In Danish) [Copenhagen].

In 1944, 298 children with asthma were followed up. In 1957, follow-up of 281 of the 293 survivors showed only 106 to be free from symptoms; 16 of these had received desensitization treatment. Thus, 90 patients, or about 30%, had outgrown the disease or had become free from symptoms after different forms of unspecific treatment. Of the 165 patients with symptoms, 135 could do full-time work, 13 found work difficult, 16 were unable to work, and 1 was mentally incapacitated. Ten patients had died, 9 of asthma and 1 of chronic bronchitis. The best chance for continued freedom from symptoms of asthma is in children in whom the disease sets in early, is of short duration, and disappears about the age of 15 years.

Lymphosarcoma in Childhood. S. A. Rosenberg, H. D. Diamond, H. W. Dargeon and L. F. Craver. New England J. Med. 259:505-512 (Sept. 11) 1958 [Boston].

At the Memorial Center for Cancer and Allied Diseases in New York the group of cancers known as lymphosarcoma were analyzed, particular attention being given to their occurrence in children. This study covers the 30-year period from 1928 to 1957, but in order to provide a follow-up period of at least 5 years, only patients in whom the disease began before 1953 are considered. Of 1,269 patients, 69 (or 5.4%) were less than 15 years of age. The authors use the term "lymphosarcoma" to include all primary malignant tumors of lymphoid origin except Hodgkin's disease. An attempt was made to exclude patients with leukemia. The increased frequency of lymphosarcoma in males was seen in the entire group, but the male preponderance was greatest in late childhood, reaching a maximum of 4.5:1.0 in the age group from 11 through 15 years. The ratio of males to females approaches unity in the very young and in the very old. Cervical lymph node enlargement is the most common presenting manifestation in children as well as in adults, but the disease in childhood presents with abdominal symptoms about twice as often as in adults. In the 15 children in whom abdominal symptoms were the initial indications of disease, exploratory laparotomy revealed primary lesions of the small intestine in 5 cases and a lesion of the ileocecal region in 1. Two of these 6 children had mesenteric lymph node involvement as well, and in 3 patients intussusception resulted from the intestinal tumor.

Roentgenographic manifestations of lymphosarcoma in children were found to parallel those seen in adults. Obstruction of the superior vena cava, with characteristic dyspnea, cyanosis, venous engorgement, and edema of the upper half of the body, which is often described as a late manifestation, was seen in 5 children (or 7.2%). Ten of the 69 children (or 14.5%) showed a transition suggesting a leukemic change. Of the 42 children with small-cell lymphosarcoma, the cases of 9 (or 21.4%) ended in leukemia, 5 of these being indistinguishable from acute leukemia. The remaining 4 were classified as leukolymphosarcoma, with incomplete bone marrow invasion or characteristic lymphosarcoma cells in the peripheral blood. One child with reticulum-cell sarcoma showed a picture of acute leukemia during the course of the disease. It was found that, when bone marrow invasion occurred in children, acute leukemia usually supervened, and the therapeutic regimen should be designed in accordance with that diagnosis.

Though the treatment of lymphosarcoma, especially in childhood, is unsatisfactory, the authors feel that judicious use of x-ray therapy continues to be the backbone of the therapeutic program and can provide relief of distressing symptoms and be lifesaving, if only for an unpredictable period. The use of the polyfunctional alkylating agents, alone and combined with adrenal steroids, provides little, if any lasting, benefit to the majority of children. The antimetabolic drugs, chiefly the folic acid antagonists, appear to be useful, particularly in children with a picture of acute leukemia. In specific problems, such as superior vena caval obstruction and spinal cord compression, the polyfunctional alkylating agents administered before radiation therapy appear to have both anticongestant and antitumor effects. The fact that 17.4% of 5-year survivals were among the children, compared with 27.7% among the adults, demonstrates the seriousness of lymphosarcoma in childhood, but it should nevertheless discourage a defeatist attitude.

UROLOGY

Serum Mucoproteins in Prostatic Carcinoma. J. A. Arcadi. J. Urol. 80:192-193 (Sept.) 1958 [Baltimore].

There frequently is an increase in the amount of protein-bound carbohydrates of blood serum in patients with carcinoma. Evidence was presented that the carbohydrate-containing protein of the serum arose from the "ground substance" of the connective tissue, which is the nonfibrillar component or intercellular cementing substance through which collagen and reticulin grow and upon which cells rest (i. e., the basement membrane). In the region of tissue injury, and around growing tumors, the protein-bound carbohydrate (glycoprotein or mucoprotein) was found to be extremely water soluble, as opposed to its relative water insolubility in normal tissue. The author presented evidence showing that the connective tissue glycoprotein of untreated prostatic cancer is quite different in appearance from that of estrogen-treated or castration-treated prostatic cancer.

Two groups of patients were studied. The control group consisted of 25 persons without clinical, roentgenologic, or biochemical evidence of prostatic cancer. The study group consisted of 33 patients with histologically proved carcinoma of the prostate. Those who were treated received Stilbestrol in a dose of 3 mg. per day and/or had a bilateral orchiectomy. Blood was drawn with the patient fasting. Mucoproteins were determined by a slightly modified Winzler method. In the control group, the values of serum mucoproteins ranged from 9 to 17.2 mg. per 100 cc.; this averages 13.2 mg. per 100 cc. In patients with untreated prostatic cancer, the values of serum mucoproteins ranged from 23.3 to 86 mg. per 100 cc.; the over-all average was 49 mg. per 100 cc. All the patients with carcinoma had elevated serum mucoprotein levels. Fourteen patients were followed as to the response of their serum mucoproteins to bilateral orchiectomy and/or Stilbestrol administration. In 12 of the 14 patients a decline in serum mucoproteins was noted 1 to 7 days after the institution of therapy. In 3 patients a rise in serum mucoproteins, after an initial decline, heralded a relapse that was not clinically evident for several more weeks. This observation suggests that the level of serum mucoproteins in prostatic cancer may be of prognostic significance. Most of the patients with prostatic cancer had metastases. It is suggested that serum mucoprotein determinations be made also in patients in whom the tumor is still confined to the prostate. The observations presented further prove the importance of the ground substance in prostatic cancer.

Impotence and the Leriche Syndrome: An Early Diagnostic Sign; Consideration of the Mechanism; Relief by Endarterectomy. V. J. O'Conor Jr. J. Urol. 80:195-198 (Sept.) 1958 [Baltimore].

A young man, whose presenting complaint was inability to maintain penile erections, was found to have early arteriosclerotic occlusion of the aortic bifurcation (Leriche syndrome). Complete return of erectile function followed aortoiliac thromboendarterectomy. Partial impotence may be the earliest manifestation of impaired pelvic blood flow and may be present with minimal occlusive disease of the aorta or iliac vessels. Impotence has been described in patients with localized iliofemoral arteritis, the mechanism being ascribed to reflex vasospasm of the pelvic arteries. In this condition, striking relief has been effected by lumbarsympathectomy. In general, partial or incomplete impotence is produced by organic disease, either neurological or, as in this case, vascular in origin. This differs distinctly from the total impotence associated with psychic disorders.

OPHTHALMOLOGY

Horner's Syndrome: An Analysis of 216 Cases. C. L. Giles and J. W. Henderson. Am. J. Ophth. 46:289-296 (Sept.) 1958 [Chicago].

The classical description of Horner's syndrome lists the components as miosis, ptosis of the upper lid, anhidrosis, and enophthalmos—all on the affected side. Clinicians have designated as Horner's syndrome many cases in which only ptosis and miosis have been present. The studies presented aim to determine the anatomic site of sympathetic interruption and the etiological factors involved in 216 patients with Horner's syndrome observed over a period of 21 years (1936 to 1957) at the University Hospital in Ann Arbor, Mich. The diagnosis had been verified by either the neurological or the ophthalmological service. The constant diagnostic features included ptosis and miosis plus a variable number of other signs.

The following conclusions were drawn from this study: 1. The most common site of interruption of the sympathetic pathway to the eye is in the sympathetic trunk and in the postganglionic fibers before they course intracranially. The upper thoracic and lower cervical anterior spinal roots are affected less than half as often as the sympathetic trunk, while the brain stem, spinal cord, and intracerebral postganglionics are only rarely affected. 2. Neoplasia, malignant far more often than benign, is the most common etiological agent. Bronchogenic and metastatic carcinomas are the most frequent malignancies, and neurofibroma and thyroid adenoma are the only significant benign tumors. Surgical procedures, nonoperative trauma, and vascular disease are less important causes of Horner's syndrome. 3. Neoplasia is the most important factor incriminated in sympathetic trunk lesions, while trauma and vascular disease are the most frequently encountered agents at the anterior spinal root and brain stem levels respectively. Interruption of the spinal cord sympathetic pathway was most commonly a result of trauma. Herpes zoster was the only lesion implicated in an intracranial postganglionic lesion. 4. Horner's syndrome is seen most commonly in the older age groups. In the first 2 decades of life trauma is the most common etiology. Malignant and benign neoplasms account for the largest percentage of sympathetic interruption in the 3rd, 4th, and 5th decades. In the group over 50 years of age malignant tumors are more likely. 5. In view of the frequently serious nature of the lesions involved in the production of a Horner's syndrome, a complete investigation is warranted.

THERAPEUTICS

Mephentermine and the Arrhythmias. M. Wilson, M. Perez-Arzola and M. J. Oppenheimer. Am. J. M. Sc. 236:300-310 (Sept.) 1958 [Philadelphia].

The clinical studies described aimed to evaluate the acute response of various cardiac arrhythmias in the abnormal heart to mephentermine sulfate, a member of the pressor amine group of drugs. Twelve patients were studied: 8 males, from 52 to 80 years, and 4 females, from 24 to 36 years of age. One patient was studied on 2 different occasions. Seven patients had arteriosclerotic heart disease; 3, hypertensive heart disease; 1, active rheumatic fever; and 1, a congenital complete heart block. Six were in chronic congestive heart failure, and one had had a recent myocardial infarction. Nine patients were receiving digitalis; one was considered to have digitalis toxicity. After a 12-lead electrocardiogram and after a long tracing of the lead that showed best either the P wave or the arrhythmia, mephentermine sulfate was given intravenously. Subsequent long tracings were taken after each administration of the drug and from 10 minutes to 4½ hours after completion of total dosage. In some cases electrocardiograms were taken the next day.

It was found that mephentermine sulfate has an antiarrhythmic effect upon the diseased human heart. This salutary action was especially noted in patients with ventricular ectopic systoles. The mechanism of action is a decrease in the refractory period, an increase in the velocity of conduction, and a positive inotropic effect. With doses up to 3 mg. per kilogram administered intravenously, there was no significant electrocardiographic effect in patients with chronic atrial fibrillation. Effective reduction in functional atrioventricular block was produced. Supraventricular tachycardia with second-degree atrioventricular block represents a contraindication to the use of mephentermine. The antifibrillatory properties of mephentermine may be of value in open heart surgery with therapeutic cardiac arrest. Theoretically, an oral preparation of mephentermine may find use as an adjuvant to digitalis in patients with chronic congestive heart failure.

Results of Treatment of Tuberculous Meningitis by Oral Administration of Neoteben. J. Gehrt. Monatsschr. Kinderh. 106:357-361 (Aug.) 1958 (In German) [Berlin].

The author reports on 70 children, between the ages of less than 2 and 14 years, with tuberculous meningitis who were treated at the pediatric clinic of the City Hospitals in Wuppertal, Germany, between 1948 and 1957. Of the 70 children, 34 were treated with streptomycin given by intramuscular and intrathecal routes; 11 of these obtained a cure, while 23 died. Seven children treated in 1951 and 1952 were given for the first few weeks or months streptomycin by intramuscular and intrathecal routes and then Neoteben, a proprietary preparation of isonicotinic acid hydrazide, given orally in doses of 10 mg. per kilogram of body weight; all 7 children obtained a cure, although 3 of them suffered permanent mental impairment. Of the remaining 29 children who were treated between 1952 and 1957, one group of 6 received combined treatment with streptomycin and Neoteben; 2 of the 6 died within the first 5 days after admission; of the surviving 4, 2 obtained a cure, and 2 died. In the other group of 23 children, who received Neoteben exclusively or Nicoteben, a compound of Neoteben and isonicotinic aldehyde thiosemicarbazone, 1 died within the first 5 days after admission; of the remaining 22, 20 obtained a cure, and 2 died. One of the 2 who died, and who had been given phenobarbital (Luminal) in addition to Neoteben, had a sudden onset of extensive hemorrhages of the skin and the mucosa in the complete absence of thrombocytes, thus presenting the picture of thrombopenic purpura. An increased allergic disposition apparently was responsible for the occurrence of the thrombopenic purpura.

The case of 1 of the 20 children who recovered, a 3½-month-old infant with miliary tuberculosis and meningitis (positive cerebrospinal fluid in animal experiments), is reported in detail. The child is at present 4 years old and completely healthy. Early institution of treatment is essential. Neoteben should be given orally immediately, even if the result of lumbar puncture at first leaves it unsettled whether the patient may have abacterial or tuberculous meningitis. Combined treatment with Neoteben orally and streptomycin intrathecally should be given a trial in patients with far-advanced meningitis. A still further improved cure rate may be expected from early additional treatment with cortisone preparations.

Initial Sensitivity to Streptomycin and Isoniazid of Mycobacteria Isolated from Previously Untreated Patients with Primary Pulmonary Tuberculosis. G. Spina, G. Mescolini and M. Zubiani. Ann. Ist. Carlo Forlanini 18:47-61 (No. 1) 1958 (In Italian) [Rome].

The authors investigated the resistance to streptomycin and to isoniazid of mycobacterium tuberculosis, the organisms being recovered from the sputum and the gastric contents of 74 patients with primary pulmonary tuberculosis who had not previously received chemotherapy. The virulence of the recovered tubercle bacilli was high, as was demonstrated by inoculating them into guinea pigs. Strains of bacilli resistant to streptomycin and/or isoniazid were found in 3 patients. The micro-organisms recovered from one patient, who was 20 years of age, proved to be resistant to streptomycin in a concentration of 10 mcg. per cubic centimeter and to isoniazid in a concentration of 0.5 mcg. per cubic centimeter. The other 2 patients were a brother and a sister, aged 5 years and 17 months respectively. The micro-organisms recovered from the boy proved to be resistant to streptomycin in a concentration of 100 mcg. per cubic centimeter and to isoniazid in a concentration of 10 mcg. per cubic centimeter. The micro-organisms from his sister were slightly resistant and only to isoniazid in a concentration of 0.1 mcg. per cubic centimeter. Both brother and sister were infected with Myco. tuberculosis at the same time and apparently from the same source—an uncle. It is, therefore, possible that the uncle spread simultaneously different strains of bacilli, each one being resistant to streptomycin and to isoniazid in varying degree. It is also likely that the authors were unable to isolate from the cultures derived from the girl those strains which were highly resistant to the 2 antibiotics. A combined treatment with streptomycin and isoniazid for 4 or 5 months brought about remission of the tuberculous disease in all 3 patients.

Four Year Evaluation of an Antihypertensive Agent. E. Roberts. J. Am. M. Women's A. 13:349-352 (Sept.) 1958 [New York].

The author investigated the long-term effects of a combination drug, which contains rauwolfia, protoveratrine, and phenoxybenzamine in fixed amounts, since there was evidence that preparations containing small amounts of several antihypertensive agents, each of which acts on a different site of the vascular complex and thereby produces a combined therapeutic effect, may be superior to larger doses of a single drug. Sixty-five patients (51 women and 14 men) were selected for evaluation on the basis of significantly elevated blood pressures and other symptoms associated with hypertension. Thirty patients were 60 years of age or older. Forty-seven patients had, in addition to elevated blood pressures, one or more of the following hypertensive symptoms: headaches, chest pains, dyspnea, insomnia, persistent fatigue, and pulse or heart consciousness. Mild neurotic symptoms, such as periodic moods of nervousness or depression, were present in 34 patients. Menopausal symptoms, manifested by menstrual disturbances, crying spells, and idiopathic gastrointestinal disturbances, were present in 17 patients.

Seven patients withdrew from the evaluation during the first month. The remaining 58 patients were treated with the compound for periods up to 4 years. Blood pressures were reduced to normotensive levels in 59% and to satisfactory levels in 24%. Of 8 patients in whom normotensive pressures had been maintained for a year with the drug, and in whom medication was then discontinued, 7 remained normotensive; the other patient had a blood pressure elevation to pretherapy levels within 4 months, but the blood pressure was again reduced to a normotensive level by resuming therapy.

Fifteen patients complained of nasal congestion as a side-effect; 7 of these dropped out of the evaluation during the first month; in the other patients the condition cleared up within 8 weeks. There were no other side-effects. Thirty patients (52%) had an excellent over-all response to the medicament, and another 18 (31%) had a good response; ten patients (17%) achieved relief of accompanying hypertensive symptoms but did not achieve lowered blood pressures. The rauwolfia-protoveratrine-phenoxybenzamine preparation, can be used when long-term antihypertensive therapy is required.

Antibiotics in Bartonellemia in Man. P. Larrea R. Arch. peruanos pat. y clín. 12:1-41 (March) 1958 (In Spanish) [Lima, Peru].

One hundred fifteen patients with bartonellosis in the septicemic phase were observed at the Hospital of the Faculty of Medicine of the University of Lima between 1947 and 1957. The treatment consisted of the administration of antibiotics; penicillin, streptomycin, tetracycline, chloramphenicol, chlortetracycline, erythromycin, and nitrofurantoin (Furadantin) were used. The patients were placed in either of 2 groups: (1) those who were hospitalized in the course of the toxic-infectious phase (with fever, bacillary forms of Bartonella organisms in the peripheral blood, and rapidly developing anemia) and (2) those who were hospitalized in the course of the immunity reaction of the body (with or without fever, coccobacillary forms of Bartonella organisms in the peripheral blood, and anemia in a stage of regeneration). In the 54 patients in the first group, all antibiotics gave satisfactory results: Fever abated within 24 hours and disappeared within 48 to 72 hours; destruction of red blood cells stopped within 48 hours, after which regeneration of the erythrocytes continued; and bacillary forms of Bartonella organisms changed into the coccobacillary forms within 24 hours and disappeared from the blood within 5 days. In the 59 patients in the second group, the results of antibiotic treatment could not be evaluated, since antibiotics act upon the bacillary but not upon the coccobacillary forms of Bartonella organisms. Destruction of the coccobacillary forms is accomplished by the reticuloendothelial system. Fifty-nine patients out of the 115 observed had complications. Salmonella organisms of various types were identified in 25 cases and other organisms in 10 cases. Twenty-nine patients with complications died.

The author concludes that antibiotics are efficacious in controlling bacillary bartonellemia if they are administered during the toxic-infectious phase of the disease. Antibiotics do not prevent the secondary complications of bartonellosis. The percentage of complications, the presence of Salmonella organisms, and the death rate are less in patients treated with chloramphenicol than in those treated with other antibiotics. Chloramphenicol has a double effect on the bacillary forms of Bartonella organisms in the blood and on Salmonella organisms.

New Therapeutic Drug (Iproniazid) in Angina Pectoris. A. Casellas Bernat. Med. clín. 30:322-328 (May) 1958 (In Spanish) [Barcelona, Spain].

Satisfactory results from the administration of Iproniazid (a derivative of isoniazid) in patients with coronary insufficiency and frequently severe crises of angina pectoris were reported in *Archivos del Instituto de cardiología de Mexico* (27:563-580

[Sept.-Oct.] 1957; abstracted, J. A. M. A. 166:1531 [March 22], 1958). Eight patients with coronary insufficiency and angina pectoris and one with intermittent claudication secondary to arteriosclerosis obliterans were treated with Iproniazid at the Hospital of the School of Cardioangiology of the University of Barcelona between November, 1957, and February, 1958. The patients were between the ages of 29 and more than 50 years. In patients with coronary insufficiency, the anginal symptoms were severe on mild exertion and in some patients even at rest. The disease had lasted between 5 months and 5 years, with previous failure of all treatment in common use for angina pectoris. The electrocardiograms of these patients showed pathological changes of the types of myocardial infarction, left branch blockage, or anterolateral ischemia. The patients had one or more of the following conditions: hypertension, marked cardiosclerosis, or syphilis. In the patient with intermittent claudication, the disease had lasted 2 years; pain restricted walking at a distance of 50 meters.

Iproniazid was given in daily doses of 150 mg. to the patients with angina pectoris and of 200 mg. to the patient with intermittent claudication. The drug was given for 10 consecutive days, after which the dose was diminished according to tolerance and individual needs. Anginal pain disappeared between the 4th and the 13th day of administration in most patients; diminution of the dose did not cause its reappearance. In one patient, however, discontinuation of treatment resulted in the reappearance of pain, which disappeared only after re-establishment of treatment for a few days. Unpleasant side-effects from the drug were mild, consisting of gastrointestinal and nervous disorders, dizziness, and difficult micturition. In no case did these secondary effects make it necessary to discontinue administration of the drug. Partial recovery of functional capacity has been obtained in all the patients. The patient with intermittent claudication has been able to walk a distance of about 1,250 meters (or three-fourths of a mile) without pain or discomfort. The author believes that Iproniazid is of value in angina pectoris and in intermittent claudication. The treatment calls for certain precautions; it should be given only by cardiologists to hospitalized patients.

The Diagnostic Meaning of the Changes of Calcium Metabolism After Administration of Sex Steroids in Mammary and Prostatic Cancer. G. M. Molinatti, F. Camanni and M. Olivetti. Minerva med. 49: 2389-2400 (June 16) 1958 (In Italian) [Turin, Italy].

The authors investigated the usefulness of a sex steroid stimulation test for hormone dependency, devised by Pearson, in 39 patients who had either mammary or prostatic cancer with osseous metastases. The test consisted in measuring calciuria, calcemia, and serum phosphorus and alkaline phosphatase levels before, during, and after the administration of sex steroids to the patients. The patients were kept on a low calcium diet throughout the investigation. Two courses of sex steroids, with a short drug-free period in between, were given to all patients. In the first course ethinyl estradiol was administered by mouth in daily doses of 0.15 mg. to 28 patients with advanced cancer of the breast, whereas testosterone propionate was given intramuscularly in daily doses of 100 mg. to 11 patients with advanced prostatic cancer. The second course consisted in the administration of testosterone to the patients with mammary cancer and in the administration of estrogens to the patients with prostatic cancer.

Before the administration of sex steroids, the urinary excretion of calcium was elevated in most patients with mammary cancer involving bones. Administration of estrogens produced a significant change in calcium and phosphorus metabolism in most patients with mammary cancer. Changes in the daily urinary excretion of calcium were the most significant metabolic response to estrogens. After administration of estrogens, calciuria increased only slightly in 2 patients who had a high calciuria level before the treatment, and it increased considerably in 7 patients who had a low calciuria level before the treatment. Calciuria changed insignificantly in 5 patients, and it decreased in 3 patients. Increased calciuria was accompanied by deterioration in clinical symptoms, and the converse developed in patients with decreased calciuria. The latter group consisted of postmenopausal women. Administration of androgens did not affect the calciuria level in patients in whom the estrogen therapy caused an increased calciuria level. Decreased calciuria was accompanied by relief of pain and by improvement in the state of health. The test devised by Pearson was a fairly accurate procedure for establishing the estrogen dependency of cancer of the breast in this series of patients and thus arriving at the most suitable endocrine treatment. The test, however, produced inconsistent responses in the daily levels of urinary excretion of calcium in patients with mammary cancer during the different phases of ovarian activity.

Before the administration of sex steroids to patients who had prostatic cancer with bone metastases, a decreased calciuria, an increased calcemia, a decreased serum phosphorus level, and an increased serum alkaline phosphatase level were observed. Administration of testosterone did not affect significantly the calcium and phosphorus metabolism. Pain, however, was intensified considerably, which required discontinuance of the treatment. Consequently, Pearson's test was not useful for investigating the androgen dependency of prostatic cancer, but it might be used for investigating the deterioration of pain related to it. Observation of changes in calcium and phosphorus metabolism after administration of sex steroids in patients with mammary or prostatic cancer is a useful diagnostic procedure for detecting bone metastases earlier than by roentgenography.

Systemic Lupus Erythematosus: Results of Treatment with Triamcinolone. E. L. Dubois. California Med. 89:195-203 (Sept.) 1958 [San Francisco].

Twenty-two women and 7 men, of an average age of 33.7 years, with active systemic lupus erythematosus were treated with triamcinolone (Aristocort), a new synthetic unsaturated derivative of prednisolone, for periods varying from 4 days to 10½ months and averaging 4.3 months. The average duration of illness from the time of onset was 92 months. Four patients were well stabilized by the administration of other steroids when they were transferred to triamcinolone, and 14 had exacerbations of varying severity. The remaining 11 patients had not recently received treatment with other steroids. Treatment with triamcinolone was instituted in these 11 patients with a daily dose varying from 4 to 40 mg. The average dose for beginning therapy in patients with mild systemic lupus erythematosus was 20.6 mg. per day. The average maintenance dose used to control mild exacerbations of the disease was 26 mg. per day. Triamcinolone proved to be 1.3 times as powerful as prednisone and 4.4 times more potent than hydrocortisone as an anti-inflammatory agent. There was no evidence of sodium retention or potassium loss.

Sixteen patients underwent upper gastrointestinal roentgenologic studies before and during treatment with triamcinolone. There was no evidence of peptic ulcers except in one patient who was receiving a daily dose of 96 mg. of the drug. Free and total gastric acidities were determined before and after subcutaneous injection of histamine in 9 patients before and during treatment with triamcinolone. No significant changes were noted in results of these tests, even in the patient who had an ulcer. No abnormal increase in uropepsin was noted in the patients in whom this factor was tested.

The pattern of clinical improvement closely paralleled that obtained by previous treatment with older steroids. Seven of the 14 patients with exacerbations during treatment with the older anti-inflammatory hormones were better controlled and felt better with triamcinolone. There was a disappearance of all the clinical and laboratory abnormalities produced by the disease, with the exception of long-standing renal involvement. A major difference between the effects produced by triamcinolone and other steroids was a tendency of the patients to progressive gradual loss of weight, partly due to loss of fluid. Moon-face appearance produced by previous therapy with other steroids did not disappear. The cutaneous side-effects, particularly moon face, hirsutism, and striae, were more pronounced than with the older steroids. The most serious side-effect was muscle weakness, which appeared in 6 patients, all women, within 4 to 32 weeks after the institution of triamcinolone therapy. The profound muscle weakness, most pronounced in the quadriceps group, gradually cleared after treatment for several weeks with another steroid. Because of the great variability in dosage and individual unpredictability of action of the new agent, one may prefer to begin treatment of the average patient with systemic lupus erythematosus with hydrocortisone, unless there is a problem of cardiorenal disease.

First Observations on Therapy with Triamcinolone: Clinical, Laboratory and Experimental Findings. R. Scalabrino. Minerva med. 49:2825-2837 (July 21) 1958 (In Italian) [Turin, Italy].

The author reports on the clinical and laboratory findings of triamcinolone therapy in 32 patients and on experimental study with the drug in rats. Rheumatic fever was present in 4 patients, rheumatoid arthritis in 4, granulocytopenia in 2, acute leukemia in 2, grave sepsis in 4, bronchial asthma in 2, scleroderma in 1, psoriasis in 1, dermatitis herpetiformis in 1, premenstrual syndrome accompanied by presence of androgen substance in the blood in 2, hay fever in 3, exudative pleuritis in 2, metastatic mammary cancer with bilateral adrenalectomy in 1, food allergy with diffuse urticaria in 1, and diabetes associated with rheumatic disease in 2.

Triamcinolone was administered to the patients in daily doses of from 6 to 60 mg. Fever began to abate 48 hours after the beginning of treatment, and the temperature returned to normal after 4 or 5 days of the therapy. An average daily dose of 16 mg. was sufficient to control fever, but high doses reaching 60 mg. a day were required for fever control in patients with rheumatoid arthritis; triamcinolone was replaced by prednisone in some febrile patients with this disease or with scleroderma. Joint pains disappeared rapidly in acute and subacute types of rheumatoid arthritis with daily dosages of from 12 to 18 mg. of triamcinolone. Diuresis increased up to 100% in this series of patients. Certain side-effects peculiar to triamcinolone therapy were observed in all the patients: headache, gastric discomfort, weakness, nausea, lack of appetite, depression, sweating, somnolence, and, in a few instances, insomnia. Triamcinolone produced side-effects common to other steroid therapy in 3 patients only; each of these exhibited moon facies and erythematous disorder of the skin, with deterioration from the symptoms in an older patient with diabetes. Arterial blood pressure varied slightly, being similar to the change with prednisone therapy. Administration of triamcinolone caused abatement of the characteristic pericardial frictional murmur in patients with rheumatic fever; likewise, the heart sounds improved. Roentgenography confirmed the clinical improvement, and the cardiac diameter decreased in some patients after 5 days of this chemotherapy. Electrocardiographic patterns showed improvement in all but the older patients. Laboratory findings revealed increase in hemoglobin level, red blood cell count, and number of granulocytes after 8 to 12 days of therapy with triamcinolone, and the erythrocyte sedimentation rate started to decrease after 3 to 5 days.

Experimental studies for comparing the effects of prednisone and of triamcinolone were made on 60 rats divided into 6 equal groups. Prednisone was given to 3 groups, triamcinolone to 2, and 1 group was used for control. Prolonged administration of triamcinolone determined involution of the adrenal cortex and the thymus even more than prednisone did. It is too early to evaluate the therapeutic effects of triamcinolone as compared with other steroids. The dosage of triamcinolone is smaller by 30% than that used in the administration of other steroids. This is advantageous for maintenance treatment of patients with asthma or allergic disorders or total adrenalectomy for mammary cancer. Triamcinolone does not produce certain undesirable effects related to steroid administration, but it brings about different effects which have not been observed in therapy with other steroids.

RADIOLOGY

Pulmonary Torulosis. L. G. Jacobs. Radiology 71: 398-403 (Sept.) 1958 [Syracuse, N. Y.].

The author reports on 10 men, between the ages of 22 and 62 years, with pulmonary torulosis who were admitted to the Veterans Administration Hospital in Oakland, Calif., during the last 10 years. Chest roentgenograms revealed consolidation of the left upper lobe in 1 patient, a granulomatous mass lesion in the right upper lobe in 1 patient, a small solitary nodule in either the left lower or the left upper lobe in 5 patients, and a small solitary nodule in the right lower lobe in 3 patients. A lobectomy was performed on the first 2 patients and a wedge resection on the other 8 patients. Microscopic examination of the surgical specimen in 8 of the patients revealed the late stage of the granuloma of torulosis, with a "caseous" necrotic center surrounded by moderately well-developed connective tissue in which groups of lymphocytes and occasional giant cells and plasma cells were seen. Spherule-like organisms were well demonstrated by employing the periodic acid-Schiff stain. All the patients were well 7 to 48 months after the resection.

A modified concept of torulosis of the lung is presented as follows. The disease is considered as a generally benign infection, healing by formation of a fibrocaseous nodule in which organisms, morphologically typical of those of Torula, are found on microscopic examination but cannot be cultured, being presumably inactive or dead. This type of lesion appears to represent most of the cases. The mortality rate is relatively high, possibly 60%, in certain patients with active disease causing progressive pulmonary or extrapulmonary lesions. In those patients with disease limited to the lung, cure by resection may be obtained, but most patients with meningeal or generalized lesions die despite any form of therapy known at the present time.

Reversible Bronchiectasis. S. W. Nelson and A. Christoforidis. Radiology 71:375-382 (Sept.) 1958 [Syracuse, N. Y.].

The authors report on 4 patients, a 17-year-old boy, a 28-year-old woman, a 10-year-old boy, and an 11-year-old girl, with bronchiectasis in whom all the bronchopulmonary segments were examined bronchographically. In order to determine whether or not there had been progression of the disease, bronchographic studies were repeated during a 15-month period. The first patient had been treated with streptomycin for an acute episode of lobar pneumonia in the lower lobe of the left lung 5 weeks before the diagnosis of bronchiectasis was made. There was no previous history of respiratory trouble, and the bronchiectasis disappeared in the 25-day interval between the first bronchogram and the second admission to hospital for contemplated surgical intervention. The second patient had a long history of cough, and the original bronchogram was justified because it was surmised that the patient might have bronchiectasis or a bronchial adenoma, either of which might have precipitated an episode of acute pneumonia and atelectasis. When bronchiectasis was found, it was, therefore, assumed to be related to the long history of productive cough; surgical intervention was felt to be advisable, but it was postponed since the patient was pregnant. A second bronchogram, which was obtained 6 months later, revealed complete disappearance of the previous changes, making operation unnecessary. In the third patient, bronchiectasis occurred in the course of acute pneumonia. The dilated bronchi in this patient returned to normal roentgenographically, and, although the patient's cough persisted, it is not probable that surgical removal of the temporarily dilated bronchi would have removed the source of so common a childhood respiratory symptom. The original bronchogram was obtained from the fourth patient because of chronic productive cough, and it was no surprise to see the bronchiectatic changes. The second bronchogram, obtained a year later, showed normal bronchial filling without evidence of bronchiectasis.

Subsequent bronchograms obtained from these patients have proved that bronchiectasis is still reversible when its presence is revealed by the original bronchograms. It is important for the radiologist to recognize and emphasize to his clinical colleagues that bronchiectasis in its early stages is frequently a reversible process, particularly in children and young adults after acute pneumonia and atelectasis. Therefore, before surgical excision is contemplated, thorough medical management, including administration of antibiotics, postural drainage, and breathing exercises, should be tried. Careful bronchography is the most reliable and practical diagnostic method for detecting bronchiectasis, and repeated bronchographic studies should be done in order to follow accurately the course of the disease.

PHYSIOLOGY

Movements of the Common Bileduct in Man: Studies with the Image Intensifier. W. Burnett and R. Shields. Lancet 2:387-390 (Aug. 23) 1958 [London].

The authors studied possible peristaltic movements in the common bile duct of 10 patients 1 or 2 weeks after cholecystectomy or choledochotomy. These studies were carried out in the unanesthetized patients by using image intensification. A water-miscible contrast medium, a 50 or 70% solution of sodium acetrizoate, was instilled at the rate of 1 cc. a minute into the common bile duct. In cases of cholecystectomy the injection was made through a ureteral catheter, which had been inserted at operation for a distance of about 1 cm. into the common bile duct through the stump of the cystic duct. If the common bile duct had been explored by choledochotomy, the injection was made through a short T-tube left in the common bile duct at operation. An initial injection of 3 cc. of the solution was made. Screening was done at this time to observe the filling of the duct. Since the duct emptied into the duodenum, further increments of the same or less volume were instilled, the amount being determined by the rate of emptying. No disturbance occurred in the patient, and no distention of the common bile duct was allowed to take place at any time. Observations were made both during the injection and afterwards. After the passage of 5 to 10 minutes for stabilization of conditions, permanent records were made by cineroentgenography simultaneously with screening.

Waves of peristalsis were observed in the common bile duct in all 10 patients studied, whether this duct was intact or had previously been explored. The waves of peristalsis were directed distally along the common bile duct toward the duodenum and propelled bile into the duodenum. Respiratory and duodenal movements were also studied; they played no great part in emptying the common bile duct under the conditions of the authors' observations. It is believed that there is sufficient muscle in the wall of the bile duct to produce these observed rhythmic movements. Due to this intrinsic muscle, the common bile duct functions as an actively contracting duct rather than as a passive transmitter of bile. This concept may modify current views on the genesis of biliary pain and permit consideration of common bile duct colic as an entity similar in nature to ureteral and intestinal colic.

BIOCHEMISTRY

Serum Phospholipids: Genetic and Environmental Influences. L. E. Schaefer, D. Adlersberg and A. G. Steinberg. Circulation 18:341-347 (Sept.) 1958 [New York].

The authors determined the phospholipid levels in the serums of 1,067 normal persons, 516 male and 551 female, between the ages of 2 and 77 years, who were part of a total sample of 1,236 persons, representing a healthy and unselected group of New York City employees and members of their families, living on Staten Island. Of the 1,067 persons, 580 belonged to 156 families, consisting of 156 fathers, 156 mothers, and 268 children of these parents. Results showed that serum phospholipid levels increased with age but in a different way for the 2 sexes. In the males, the levels remained practically constant until the age of 20 years, then they rose sharply to the age of 32, after which they remained constant until the age of 60. In the females, the levels remained constant until the age of 32 years, and then they rose gradually until the age of 60. These age-sex changes in serum phospholipid levels were similar to those observed for serum cholesterol levels, but they were of lesser magnitude.

Correlation coefficients in the members of the 156 families indicated the existence of a genetic factor determining serum phospholipid levels in healthy persons; negative mother-father and positive parent-child and sibling-sibling correlations were revealed. These observations suggest that common environment in a family does not result in common serum phospholipid levels unless blood relationship exists, and that diet cannot be the only factor in determining serum phospholipid levels of healthy persons. Because of the age-sex variations of serum phospholipid levels and serum cholesterol levels, no single arbitrary line can be drawn between normal and abnormally elevated levels of these 2 serum lipid fractions. The levels are distributed as continuous variables. The upper 5% levels of each age and sex group may be utilized to characterize hyperphospholipidemia and hypercholesterolemia respectively.

BOOK REVIEWS

Essentials of Pediatrics. By Philip C. Jeans, A.B., M.D., F. Howell Wright, B.S., M.D., Professor of Pediatrics, University of Chicago, Chicago, and Florence G. Blake, R.N., M.A., Associate Professor of Nursing Education (Nursing Care of Children), University of Chicago. Sixth edition. Cloth. $6. Pp. 714, with 115 illustrations. J. B. Lippincott Company, East Washington Sq., Philadelphia 5; 4865 Western Ave., Montreal 6, Canada; Pitman Medical Publishing Company, Ltd., 45 New Oxford St., London, W. C. 1, England, 1958.

Recent advances in pediatrics necessitate frequent revision of texts designed for teaching. This volume should be especially helpful for the student and graduate nurse as a textbook since it conveys information concerning basic principles and places proper emphasis on changing trends. Both normal and abnormal factors in physical and emotional growth and development are considered. The role of the nurse is a complex involving human relationships and adjustments in addition to competence and skill in the practice of her profession. A special feature of this new edition is the inclusion of a section at the end of each chapter entitled, "Situations for Further Study," and a bibliography. This enables the serious student to apply in practical fashion some of the knowledge obtained in the preceding chapter. The order of presentation of the material illustrates many facets of the problems of pediatric nursing. An essential foundation for the management of disease involves proper nursing care and a knowledge of the normal. Reorganization has improved the effectiveness of the book as a text.

Thorough coverage of the subject has been accomplished within the limitations of a single volume. Unit 1 covers expected growth and development including requirements for optional nutrition; unit 2 considers the kinds, incidence, and severity of diseases among children, and preventive measures; unit 3 treats the rudiments of nursing care, both physical and psychological; unit 4 discusses in detail diseases and special problems relating to the nursing care of the infant; and unit 5 discusses diseases characteristic of the older child, and includes such diversified subjects as allergy, burns, obesity, and the collagen diseases. The revised edition includes important advances in knowledge. Illustrations are informative, and an index is provided. This text should serve as a practical aid for more complete understanding of the child in health and disease.

Radiation Protection. By Carl B. Braestrup, Director, Physics Laboratory, Francis Delafield Hospital, New York, and Harold O. Wyckoff, Chief, Radiation Physics Laboratory, National Bureau of Standards, Washington, D. C. Cloth. $10.50. Pp. 361, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1958.

This clear and readable textbook provides a compilation of information covering the practical aspects of protection from x-rays, gamma rays, and particulate ionizing radiation. In addition to giving the background underlying the practice of radiation protection, it provides the tables, graphs, and formulas essential for determining proper protective barriers, particularly when used in conjunction with the various handbooks of the National Committee on Radiation Protection. Both Braestrup and Wyckoff are experienced workers in the field, and many useful practical points are included. In view of the current interest in the measurement of beta rays, rather more emphasis might have been laid on beta ray instrumentation. The chapter on biological effects of radiation by Evans and Lough is factual but overly condensed. Specific bibliographic references for the several sections of the chapter would have been much more helpful than a general bibliography for the chapter as a whole. Thus, the reader interested in learning more about specific ionization or linear energy transfer has been provided no guidance as to where to turn for added information. In reading a small volume one can always be critical of the bibliographic references chosen, but this is perhaps not fair. While it may be unfair to criticize the particular choice of bibliographic references, there are a few particularly valuable references that have been omitted such as Trout and Gager, Speare, or Richards. The method for determining radium leakage on page 301 is outmoded. The electroplating technique is probably 1,000 times more sensitive and is the method generally preferred by insurance companies.

Fit to Teach: Yearbook on Teacher Health. [Fred V. Hein, editor.] Cloth. $3.50. Pp. 249, with illustrations. American Association for Health, Physical Education, and Recreation, a department of National Education Association, 1201 Sixteenth St., N. W., Washington 6, D. C., 1957.

Twenty years have elasped since the first edition of this book appeared. This new edition has been completely rewritten jointly by a group of experts in health education and although the emphasis throughout is on physical and mental health in teachers, most of what is said is applicable to fitness

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

in general. The book was written as a practical guide for teachers, school administrators, and all others concerned with the health of teachers. Although the mental, emotional, social, and physical aspects of the subject are sometimes discussed separately, their interrelationship is constantly stressed. Each chapter has a bibliography and those chapters that readily lend themselves to summary have one. The major subjects discussed include (1) the task of the teacher, (2) resources for health protection and promotion, (3) health problems, (4) the teacher's health and the pupil, (5) school organization and teacher health, (6) administrative responsibilities for teacher health, (7) personal responsibility for physical and mental health, (8) the community's responsibility for teacher health, (9) health problems of advancing years, (10) health education for teachers, and (11) teacher *health and professional relations. There is no index.*

Diseases of the Liver and Biliary System. By Sheila Sherlock, M.D., F.R.C.P., M.R.C.P., Physician and Lecturer, Department of Medicine, Postgraduate Medical School, University of London, London. Second edition. Cloth. $11.50. Pp. 719, with 213 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1958.

This edition of a well-known book brings the material up to date. The general format has remained unaltered, but important additions have been made *in the sections on bile pigment metabolism,* drug-induced jaundice, and hepatic coma. The section on jaundice in infancy has been expanded to include a general discussion of hepatic disease in childhood. Much other new material has been added, including electron microscopy of the liver cell, serum transaminases, circulatory phenomena in liver failure, penicillamine in dermatitis exfoliativa, and epidemiology in primary hepatic cancer. More than 500 new references and 37 new figures have been added. This book continues to be one of the best general treatises on liver disease. The style is clear and concise and the material is presented in such a way as to be useful to the practitioner as well as to the specialist in the field. It is highly recommended.

Etiology and Treatment of Leukemia: Proceedings of the First Louisiana Cancer Conference. Edited by Walter J. Burdette, Ph.D., M.D., F.A.C.S., Professor and Head of Department of Surgery and Director of Laboratory of Clinical Biology, University of Utah College of Medicine, Salt Lake City. Sponsored by Louisiana Division, American Cancer Society, Inc., Louisiana State University School of Medicine, and Tulane University School of Medicine. Cloth. $4 Pp. 167, with illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1958.

These papers deal with the cause, diagnosis, and treatment of leukemia. For the most part the presentation is by well-known authorities. Highlights of the book are the informal discussions following each paper which often clarify obscure points, but even more often point out glaring gaps in our knowledge of fundamental aspects of the disease, its biologic behavior, and unpredictable responsiveness. A beautiful summary paper is presented by the editor. There is an excellent bibliography. The book is well indexed both as to subject matter and as to authors. The typography is beautiful. Unfortunately this book will be of prime interest only to workers in a limited field, but members of most disciplines in medicine could profit by reading it.

Electrocardiogram Clinics. By Joseph E. F. Riseman, M.D Assistant Clinical Professor of Medicine, Harvard Medica School, Boston, and Elliot L. Sagall, M.D., Instructor i Medicine, Harvard Medical School. Cloth. $10.50. Pp. 259 with illustrations. The Macmillan Company, 60 Fifth Ave New York 11, 1958.

This volume presents an original concept in the study of cardiovascular disease. For example, a series of electrocardiograms is reproduced and each case is discussed briefly. The net result is fortunate, as it has been possible to limit the presentations to items of importance in reaching an accurate diagnosis, thus materially increasing the utility of the text. In tables 1 and 2 the normal variations of the ST segments and T waves are set forth for the three standard leads as well as for leads aVR, aVL, aVF, and V_2. In that table the ST displacements are pre*sented for all of the commonly recorded leads. This is the general procedure throughout the book.* The book is an addition of some value to the growing literature of cardiovascular disease and its precise recognition. It can be recommended to those interested in the correct diagnosis of cardiovascular disease or suspected cardiovascular disease.

Human Parturition: Normal and Abnormal Labor. By Norman F. Miller, B.S., M.D., F.A.C.S., Professor of Obstetrics and Gynecology, University of Michigan Medical School, Ann Arbor, T. N. Evans, A.B., M.D., F.A.C.S., Associate Professor of Obstetrics and Gynecology, University of Michigan Medical School, and R. L. Haas, A.B., M.D., F.A.C.S. Cloth. $7.50. Pp. 248, with 67 illustrations: Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1958.

This book is an excellent contribution to one area of obstetrics, namely, labor. It deals with normal and abnormal labor in a concise, clear, and interesting manner. Much time, effort, and research went into the preparation of this volume. Many of its contents are in outline form, easy to understand and to follow, with frequent and excellent illustrations, many of them pen and ink drawings which are unusually attractive. Basic factors and mechanisms involved in human parturition are clearly delineated. This is followed by a description and visual portrayal of abnormal labor and a discussion of complications. This holds the reader's interest throughout. This book should be of great value to the student, general practitioner, and specialist

QUESTIONS AND ANSWERS

TREATMENT OF METASTATIC THYROID CARCINOMA

To the Editor:—*A 33-year-old woman had a thyroidectomy in 1949 for a papillary thyroid carcinoma. A few months ago, she developed an upper respiratory infection followed by a pneumonitis on the right side. X-ray of the chest revealed a well-defined, round, soft density about the size of a quarter in the right lower lobe. The lesion suggested a metastatic nodule. A roentgenogram taken six months earlier had revealed no pathology. A right lower lobectomy was performed, and histological diagnosis was papillary thyroid carcinoma, metastatic. This patient made an uneventful recovery and is now clinically asymptomatic. A recent chest roentgenogram revealed two small-sized nodules on the left side. Radioactive iodine uptake was zero. What management should be considered at this time? Is chemotherapy indicated? What is the prognosis?*

M.D., Connecticut.

Answer.—The zero uptake of radioactive iodine (I^{131}) in the neck by this patient suggests that the original operation was a total thyroidectomy. It is not stated whether the patient is currently on thyroid therapy. Such treatment could cause a low neck uptake despite persistence of thyroid tissue. Assuming the former possibility to be correct, however, and that she is not receiving thyroid, the first step in the management of this particular patient is to administer a large test dose of I^{131} ($1\ \mu c$) for measurement of retention of I^{131} at 24 hours and for scanning over the chest nodules and general body. Although the tumor is papillary, and hence would be expected to have no uptake, frequently there are follicular components in the metastases and these may be functional. Also, a complete skeletal roentgenographic survey for metastases is indicated. Retention of more than 40% of the test dose of I^{131} in this particular patient would make possible therapy with I^{131}; less would exclude this. However, it is more likely that I^{131} therapy will not be possible in view of the histology of the original tumor and its right lung metastasis. This leaves two other methods of approach: thyroid or triiodothyronine in large doses and x-radiation to the left hemithorax. It can be said immediately that no recommendation will be acceptable to all physicians in the field. This consultant would first favor thyroid or triiodothyronine for as long as the lesions improve or remain static. I^{131} therapy, if feasible, would be used next and, finally, x-ray therapy. Radiation injury to the lungs is to be avoided in either of these latter instances. The combination of thyroid and x-ray therapy might provide a more intensive approach, but any result would be difficult to interpret. Methyltestosterone therapy is useless, and other chemotherapeutic agents have not been adequately tried. The prognosis would be four to five years as an average but could be considerably longer.

VITAMIN D AND SUNBATHING

To the Editor:—*To what extent does suntanning sustained during one season of the year increase calcium absorption? Can this absorption be equated with vitamin D given orally? Can vitamin D intoxication result from sustained exposure to the sun, as beach bathers are in the habit of doing? Is kidney stone formation a special liability for those addicted to sunbathing?*

Richard B. Gross, M.D., Bronx, N. Y.

Answer.—There is no way at present of accurately measuring the amount of vitamin D formed in the human body by the action of the ultraviolet rays of the sun on the dehydrocholesterol present in the skin. Whether the vitamin D obtained from the sun would increase calcium absorption would depend on the amount of calcium in the diet. When adults are receiving only small amounts of calcium, ingestion of vitamin D neither increases the utilization of the calcium that is ingested nor decreases the requirement for calcium. While vitamin D is important in the metabolism of both calcium and phosphorus, this consultant is not familiar with any studies giving quantitative figures for this relationship. The need for vitamin D is greatest during periods of rapid growth. The need for supplemental vitamin D by vigorous adults leading a normal life appears to be minimal. According to the Food and Nutrition Board of the National Research Council (Recommended Dietary Allowances, Publication 589, 1958), "Evidence is good that vitamin D is needed throughout the growth period, but the actual requirement has not been determined accurately. It is known, however, that 400 units daily is ample for good calcium retention in children." Hypervitaminosis D results only from a prolonged, greatly excessive intake of the vitamin, and it is extremely unlikely that mere exposure to sunlight, even to the extent practiced by "sunbathers," would

---

Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

result in anything approaching toxic levels of vitamin D. It has been shown that 100,000 international units per day in adults will result in toxic symptoms. The amount manufactured by sunlight on the skin certainly does not approach this level. This consultant is unaware of any evidence correlating sunbathing with the formation of kidney stones.

TREATMENT OF INSECT STINGS

To the Editor:—*Please discuss treatment of insect bites and stings in general, with special reference to bites of honey bees and red ants.*

J. M. Hesser, Benson, Ariz.

Answer.—In general, the reactions to insect bites can be treated prophylactically with repellents and symptomatically with common local antipruritic agents. Orally given antihistamines will add somewhat to the comfort. The reaction usually is self-limiting. Capturing and identifying the offending insect will assist vector control agents to institute effective measures. A few insects, especially ticks and larval forms of mites and flies, are buried in part or entirely beneath the skin surface. In a number of such instances, excision is necessary. Secondary infection may vary from a slight pustule to a large abscess, and treatment is dictated by the character of the lesion. In circumstances of repeated bites and secondary pustulation, as often occurs with flea bites, treatment with staphylococcus vaccine may reduce the unsightly residual discoloration from such infected lesions. Allergic reaction to bites, especially of the mosquito, deer fly, black fly, and flea, is treated with frequent success by "desensitization" injections of an extract made from the offending insect. The questioner is referred to an excellent article on this subject by Allington and Allington (*J. A. M. A.* **155**:240-247 [May 15] 1954).

With specific reference to the order Hymenoptera, and especially to the honey bee and red ant, the most dramatic effect is the anaphylactic reaction which is responsible for more deaths in a year than from the bite of poisonous snakes. The literature is replete with reports of these dramatic allergic incidences and descriptions of treatment wit symptomatic and specific measures. Morhous (*J. A. M. A.* **141**:193 [Sept. 17] 1949) reports o ant bites. Prince and Secrest (*J. Allergy* 10:379 1939) discuss allergic reactions to various member of this order. Treatment of the ordinary local discomfort of stings from the honey bee and the re ant has encompassed a vast number of home remedies and pharmaceuticals. Since the venom of re ant is presumed to contain an appreciable amoun of formic acid and since the stinging apparatus o the honey bee contains both acid and alkalin venom sacs, cold packs containing baking soda would provide the preferable home remedy. Cryotherapy (application of cold in the form of ice cubes or ice bag) will provide the most comfort. Since the venom sac of the honey bee is left in the victim to continue its pumping action, this should be removed—not by grasping with tweezers to promote the injection of more venom but, preferably, by scraping off with a pen knife or with the fingernail. Local applications of antipruritic ointments and orally given antihistamines may give relief from persistent discomfort.

SMOKING AND HEADACHES

To the Editor:—*A 55-year-old man has had chronic, daily headaches for approximately 10 years. The headaches are classified as the atypical vascular tension type. Ordinary drug therapy has been of no avail. The results of extensive investigations, including skull roentgenograms, electroencephalograms, cervical spine x-rays, and numerous blood studies, have been entirely within normal limits. His general physical condition and health status is otherwise unimpaired except for the presence of mild emphysema. He smokes habitually and excessively, averaging three to four packs of cigarettes per day, and has smoked this much for the past 35 years. Is it possible that nicotine in such an excessive amount could be the etiological factor in this patient's cephalgia?*

Alexander Wallace III, M.D., Los Angeles.

Answer.—It is difficult to state whether the excessive use of tobacco is the cause of this patient's headache or not. Excessive use of tobacco has been known to induce headache, insomnia, vertigo, and a variety of other symptoms. Tobacco amblyopia is observed occasionally. An individual absorbs about 2.5 to 3.5 mg. of nicotine from smoking a cigarette, and the effects are comparable to those noted after the intravenous injection of 1 mg. of nicotine. There are many agents in tobacco smoke, but the reactions to smoking can be attributed almost entirely to the nicotine content of the tobacco. The nicotine content amounts to about 2% in the average cigarette and to about 1% in so-called denicotinized preparations. Nicotine is a peripheral vasoconstricting agent. Prompt cutaneous vasoconstriction, as well as constriction of the retinal arterioles, can be demonstrated in smokers as well as in nonsmokers. Nicotine has no therapeutic value. It would be interesting to observe the patient's reactions if he stopped smoking even for only a few days. This patient probably has a so-called tension headache, and excessive smoking, like the headache itself, may be an expression of an anxiety state.

INDURATION OF CORPORA CAVERNOSA

To the Editor:—*Please give information regarding the most efficacious treatment of induration of the corpora cavernosa (Peyronie's disease).*

M. D., Louisiana.

Answer.—The treatment of induration of the corpora cavernosa has not been satisfactory in spite of the many therapeutic suggestions made in recent years. There is a long list of methods which might be tried, some of which have been reported to bring relief, but none has proved to be uniformly successful. In general, the reports have been more favorable in the early stages of the disease. When the tissue changes have gone on to extensive fibrous scar tissue with destruction of the erectile tissue or with bone formation, therapeutic measures have been less satisfactory. In recent years, injection of hydrocortisone into the fibrous plaques has been recommended even though the technical procedures employed have not always been satisfactory. Application of radium or x-ray therapy has proved beneficial in some cases, particularly in relieving any painful symptoms which may be present. In advanced cases, surgery has been advocated by Lowsley, who reported a number of permanent cures. Many of his American colleagues, however, failed to corroborate his claims. Fogh-Andersen (*Acta chir. scandinav.* 113:45, 1957) recently reported excellent results in a series of patients operated on by surgical removal of the fibrous areas according to Lowsley's techniques. It should be remembered, however, that in many cases the symptoms present will gradually become ameliorated spontaneously.

Answer.—Induration of the corpora cavernosa has been called, besides Peyronie's disease, fibrosis of the corpora cavernosa, fibrosclerosis of Buck's fascia, and chronic chordee. It is due to a fibrous infiltration of the wall of Buck's fascia which, of course, lines the venous spaces and constitutes the bodies called the corpora cavernosa. The effect of this disease is to cause a crooking of the penis when there is an erection by preventing the normal distention of the corpora cavernosa. Many things have been incriminated as being etiological factors in the development of this disease; however, none of them has been verified. The cause of the disease is not known. It is not due to syphilis, diabetes, arteriosclerosis, or any other individual lesion; neither is it associated with a gouty diathesis. The only possible factor connected with induration of the corpora cavernosa has been the occasional coexistence of Dupuytren's contracture of the hand. Since the latter condition has responded by softening with large doses of vitamin E, this has been an accepted treatment of induration of the corpora cavernosa for the past 10 or 15 years. It is true that occasionally the fibrosis or cavernositis, as it is sometimes called, will soften up and respond to the ingestion of vitamin E over a period of several months. This is usually given in the form of tocopherol acetate, 100 mg. three times a day. X-ray, radium, and other types of irradiation therapy have been used and have been reported as being somewhat helpful in a limited number of instances. The infusion of heat by use of diathermy electrodes has been tried, and the fibrosis has been softened in a few instances. More recently, with the introduction of such substances as hyaluronidase, hydrocortisone, and chymotrypsin, attempts have been made to inject the fibrosed area directly. Much has been claimed for some individual patients for this type of therapy. However, this consultant has given every one of these methods an honest opportunity, and in practically no instance has there been any improvement in the condition. Some patients have had less pain, where pain was a feature, and this is not usually the case. At the present time, it might be said that there is no efficacious treatment of this disease. Occasionally, the disease disappears or partially disappears spontaneously without any treatment whatsoever. There are some instances where history of injury to the corpora cavernosa can be elicited prior to the development of the induration. In these patients, the prognosis is usually better than in those in whom it develops insidiously without any history of trauma. Apparently, there is a resorption of the fibrotic process in the cases that follow a hemorrhage or fibrous replacement of the hemorrhagic area.

PREGNANCY AFTER MASTECTOMY

To the Editor:—*A 40-year-old woman had a radical mastectomy two years ago. She wants to have children; what advice should be given? Has a mother in a similar case successfully borne a baby?*

M.D., Minnesota.

Answer.—The problem posed by pregnancy after mastectomy is not so much a question of the ability to carry the pregnancy to a successful termination as it is a question of unfavorable effects on the ultimate prognosis of the mother. It is difficult to find data on such cases. A colleague has reported on a 45-year-old patient who was delivered of a normal baby three years after a radical mastectomy for mammary carcinoma with metastases. Five years after the birth of her child the mother was without evidence of disease. The poor prognosis of mammary carcinoma developing during pregnancy is recognized and is considered to be related to the outpouring of estrogen occurring at this time (Haagensen, Diseases of the Breast, Philadelphia, W. B. Saunders Company, 1956). However, it is now established that approximately 40-45% of patients with metastatic mammary carcinoma respond favorably for a limited period of time to female hormone therapy. There is no way of determining whether the primary breast tumor was the type which might be aggravated or the type which could be controlled by estrogen in a patient who has no evidence of tumor at this time. One might assume that the patient in question has, at the most, a 55% chance of worsening her disease and a possible chance of improving it by pregnancy. A further practical consideration, however, is the over-all prognosis for all mammary cancer patients of only a 33% five-year survival rate (Organized Clinical Investigation of Cancer, 10th Report, 1936-1953, University of Michigan). In view of these statistics one might not want to start a family.

NEPHROTIC SYNDROME

To the Editor:—*Three months ago, a man, aged 38, noticed swelling of the ankles (edema) extending to the legs. Findings on examination were normal, except for a large amount of albumin in the urine. The edema varies from time to time—sometimes more, sometimes less—but the albumin in the urine persists. Tests and results are as follows: total protein level, 4.4 Gm.%; albumin level, 2.6 Gm.%; globulin level, 1.8 Gm.%; albumin-globulin ratio, 1.5; prothrombin time, 13 seconds; prothrombin activity, 100%; Fishberg concentration test: first specimen, specific gravity 1.005, second, 1.011, and third, 1.010 (normal, at least one specimen with specific gravity of 1.025 or more); blood urea nitrogen level, 16 mg.%; and phenolsulfonphthalein excretion: first specimen (65 cc.), 45%, second (50 cc.), 25%, third (95 cc.), 7%, and fourth (40 cc.), 5%, with total dye excreted, 82% (normal, more than 60%). How should this case be managed?*

Michael Austin, M.D., Reading, Pa.

Answer.—The patient with edema, heavy proteinuria, hypoproteinemia, and normal renal function, as tested with phenolsulfonphthalein, is evidently suffering from a nephrotic syndrome. This diagnosis would be even more probable if hypercholesteremia were present. Nephrotic syndrome is usually due to chronic glomerulonephritis. More and more evidence is accumulated that nephrotic syndrome caused by chronic nephritis may develop after a severe attack of allergy due, for instance, to poison ivy, poison oak, or insect bites. In all cases of nephrotic syndrome, the possibility of amyloid of the kidney, liver puncture, systemic lupus erythematosus (search for L. E. cells), or syphilis must be investigated. In nephrotic syndrome due to glomerulonephritis or to systemic lupus erythematosus, corticosteroids may have a favorable influence. Patients with chronic glomerulonephritis often improve by a long sojourn in the desert climate.

TESTICULAR PAIN

To the Editor:—*A 42-year-old man gives a history of having a crushing injury to both testes 15 years ago. He states that intercourse proceeds normally until just before ejaculation and that he then has sharp pain in both testes and loses erection without ejaculation. He also states that after intercourse both testes are painful for a period of five days. The patient wishes information as to whether removal of both testes would allow him to have intercourse without pain. Would testosterone prevent him from developing a feminine appearance?*

Howard V. Weems, M.D., Sebring, Fla.

Answer.—Unfortunately, no mention is made of the extent of the injury to the testes. Presumably the testicular tissue is preserved, and, even though spermatogenesis may be depressed, hormone secretion is proceeding at a normal rate. In that event, it is most likely that the patient's present difficulties have no relation to the injury. Partial or complete loss of potency is not unusual at this age, being generally attributed to psychogenic disturbances rather than to hormone deficiency. The pain may be psychogenic also or may result from epididymal distention which accompanies sexual excitement without ejaculation. Castration seems to be too drastic, even if it ultimately solves the patient's problem. If operation is contemplated, bilateral epididymectomy should suffice insofar as the pain is concerned. The administration of testosterone after castration will prevent development of a feminine appearance. However, the need for continued administration of the drug, which is at best a poor substitute, leads this consultant to the conclusion that the remarkable organs which nature has provided should remain undisturbed.

PITYRIASIS VERSICOLOR

To the Editor:—*A skin biopsy of a 25-year-old man revealed pityriasis versicolor. These lesions have been present for 10 years and are slowly covering more area. At present they cover half of the trunk and arms. What is the treatment for this condition?*

M.D., Texas.

Answer.—To perform a biopsy in order to establish a diagnosis of pityriasis versicolor is to do things the hard way. The disease responds to treatment with most any fungicidal preparation, such as dilute Whitfield's ointment or mild concentrations of salicylic acid and sulphur precipitate in combination. Sponging the affected areas with 10% aqueous solution of sodium hypochlorite is effective, as is washing with selenium sulfide shampoo. With all methods, however, the condition is apt to recur.

HARELIP AND CLEFT PALATE

To the Editor:—*A patient with cleft palate and harelip, whose father also had harelip, is now married and wants to know what will help avoid this defect in his children. In a medical periodical it was stated that these conditions are due to a lack of certain vitamins. If this is true, what vitamins should be used?*

Irving S. Weinstein, M.D., New Rochelle, N. Y.

Answer.—There has been in the past some discussion about the relationship of vitamin deficiency to cleft palate and cleft lip. However, this has only been a theory which was talked about but quickly exploded. From present knowledge, there is absolutely no relationship between cleft palate and cleft lip and vitamin deficiency. The mere fact that a parent or a relative of a parent has or has had a cleft palate or cleft lip does not mean that the offspring will also be so afflicted. In the experience of the writer, approximately 65% of all persons with cleft palate and cleft lips do not have a history of a similar deformity in the family. However, one must consider that the offspring of a parent with a cleft palate or a cleft lip will have a larger chance of being born with such a deformity. There is no way known today to positively prevent children from being born with this deformity. The only thing that can safely be said is that under proper care, during the first trimester particularly, the possibilities of a normal birth are increased. There is no way to prognosticate the probability of a cleft palate or cleft lip. This consultant has seen normal children born to parents with cleft palate and/or cleft lip and vice versa. The real cause is not known at the present time.

VITILIGO

To the Editor:—*What is the possibility that a product with the following ingredients may cause vitiligo? It contains less than 4% each of isopropyl alcohol, alkyl aryl sodium sulfonate, sodium metasilicate, and sodium orthosilicate and less than 1% each of sodium tripolyphosphate, alkylphenyl of polyethylene glycol, and coloring. The product is 90% water.*

Norman W. Brickson, M.D., Beaver Dam. Wis.

Answer.—There is a noticeable percentage of individuals who possess the somewhat embarrassing characteristic of losing the skin pigment in areas which have been the seat of an inflammatory process. The degree of hypersensitivity is variable. Alkyl aryl sodium sulfonate is a member of the anionic surfactants, which are highly defatting to the skin and, thus, are potentially irritants. Sodium metasilicate and orthosilicate are strongly alkaline and, as such, may be irritating. In the presence of acid there may be formed silicic acid. Alkylphenyl of polyethelene glycol is a nonionic surfactant and is usually harmless to the skin. The method of approach in this matter would be to secure portions of solutions with the above-mentioned percentage and do patch tests. These should be repeated on the same areas if results are doubtful. As some of these agents are capable of producing a dermatitis, and inflammatory conditions produce loss of pigment at the point of contact in some individuals, the product may cause vitiligo.

SPINAL FORM OF HEREDITARY SCLEROSIS

To the Editor:—*Has corticosteroid or ACTH therapy been used in the treatment of the spinal form of hereditary sclerosis (Friedrich's ataxia)? This diagnosis was established in a brother and sister, 10 and 12 years of age, respectively, about one year ago. Incoordination and ataxia are progressing rapidly, and the children fall frequently; thus, any increased tendency to fracture would be a practical consideration. Is any organization making study of this condition in the United States?* *M.D., Michigan.*

Answer.—A rapid worsening of disability between the ages of 10 and 15 years is common in the classic type of hereditary sclerosis. No agent has yet been found to modify the course of the disease. ACTH and corticosteroids have not been tried extensively, because the pathology of the disease does not resemble that of diseases when these substances have been effective. In the few cases where ACTH or steroids have been tried, there has been no effect. No organization is known to be studying this condition in the United States, but every neurological department has studied the pathology of cases of this disease and the genetics have been extensively described. The difficulty is the absence of any clue as to the underlying defect, which probably concerns some aspect of cellular metabolism.

RECURRENT TONSIL INFECTION

To the Editor:—*Please provide information on the medical treatment of recurrent infection of cryptic tonsils.*

P. Pellegrini, M.D., Santa Marinella, Italy.

Answer.—The cheesy material that can be expressed from the crypts of the tonsils is made up of keratin from desquamated epithelium and is a normal condition which does not require treatment. In tonsils which have previously been infected, scar tissue may have sealed the crypts and small abscesses may occur in them. This condition is not known to cause any general or local symptoms of clinical importance. The only symptom that is caused by concretions in tonsillar crypts is foul-smelling breath. It has been advised that with pressure on the anterior pillar of the tonsil this material can be expressed from the crypts. This can be done whenever it is thought necessary.

MALIGNANT WITH BENIGN TUMORS

To the Editor:—*Is there any significant difference in the incidence of malignant tumors in patients afflicted with long-standing benign tumors? What difference is there in the incidence of malignant tumors of the genitalia or other parts of the body in women with chronic fibroids and in women of the same age group without fibroid or other benign tumors? These questions have no reference to the occurrence of malignant degeneration of benign tumors.*

Samuel Dessen, M.D., Chicago.

Answer.—As far as is known, there is significant difference neither in the incidence of malignant tumors in patients with benign tumors as compared with those without benign tumors nor in the frequency of malignant growths for different benign neoplasms. Likewise, there is no proof that there is an increased frequency of carcinoma in patients with leiomyoma, although in the past several gynecologists thought this was so. Intramural and subserous myomas can have no effect in producing malignancies of the endometrium, but submucous myomas which can produce disturbances in the endometrium theoretically may lead to malignancy. However, there is no definite evidence of this.

ANAPHYLAXIS DURING ANESTHESIA

To the Editor:—*Is it true that a person under general anesthesia (for example, plane 1 of stage 3) does not suffer an anaphylactic or severe allergic reaction if exposed to what, for this person, is normally strongly allergenic? Also, would it be possible as a general procedure to administer tetanus antitoxin (equine or bovine) to a patient under general anesthesia with assurance that an anaphylactic reaction would not occur?*

Tom Roe, M.D., Savannah, Tenn.

Answer.—The question is apparently prompted by reports of early observations on experimental anaphylaxis that animals in deep anesthesia could not be thrown into anaphylactic shock. Theoretically, it would appear that this should apply to humans as well, but unfortunately this is not completely true. At the most, one might obtain a subdued or delayed reaction. This is believed to be due to general muscular relaxation rather than interference with the hypersensitive mechanism. There is no assurance that equine or bovine tetanus antitoxin can be given with impunity to a sensitive individual under general anesthesia.

DEAFNESS AND USE OF EARPLUGS

To the Editor:—*A patient is gradually going deaf. For a number of years she has used a dictating machine, to which she listens through ear plugs. Is there any evidence that the long-continued use of ear plugs might lead to deafness?*

Clifford L. Graves, M.D., La Jolla, Calif.

Answer.—There have never been findings to support any loss of hearing due to long-continued use of ear plugs relating to a dictating machine. There may be irritation to the canal from the ear plugs, which in some cases leads to external otitis and edema.

PITYRIASIS ROSEA

To the Editor:—*Three girls in one family have pityriasis rosea at approximately two-year intervals. What is known of its etiology?*

Robert S. Srigley, M.D., Altus, Okla.

Answer.—The cause of pityriasis rosea is unknown. Its rapidly developing, widespread, symmetrical lesions and the conferred immunity suggest an infectious basis. Although no specific agent has been demonstrated, a viral origin seems most likely.

REMINDING PATIENTS TO OBTAIN IMMUNIZATIONS

To the Editor:—*Please give advice on the type of letter that could be sent to patients reminding them to obtain poliomyelitis immunizations.*

Timothy A. Lamphier, M.D., Boston.

Answer.—Since people often forget to start or finish the available preventive inoculation series, sending of reminders by physicians is heartily approved of. In fact, the American Medical Association has prepared two cards which physicians may use to remind patients to start or finish poliomyelitis series, and these are available free of charge. If a physician prefers to send a personal letter to his patients, he should remind them that it is time to get a second or third injection if they have already started the series or urge them to begin the series if they have not done so. Attention might be called, at present, to the Detroit epidemic, with the statement that poliomyelitis is still not completely wiped out and can spring up where people have not obtained immunization. The letter should indicate only concern with the patient's health. Also, it is suggested that the patient be told to go to "the doctor of his choice" for the injections rather than specifically to the reminding physician. It may be desirable to suggest a fourth immunization dose to patients living in an epidemic area or traveling to a place where they might need additional protection.

WASHINGTON NEWS

FROM THE WASHINGTON OFFICE OF THE AMERICAN MEDICAL ASSOCIATION

Health Care of Aged Remains Major Subject for Discussion . .
Consultant Group Starts on Problems of Medical Education . .
HEW Drafts Board Program to Combat Air Pollution Menace . .
"Provisional Qualification" to Be Offered Foreign M.D.'s . .

HEALTH CARE OF AGED CONTINUES AS MAJOR DISCUSSION SUBJECT

Secretary Flemming's "listening" conferences with leaders of national organizations concerned with health, education, and welfare are producing a variety of views on a major topic—the health care of the aged.

The question arose early in the first of three meetings on "health problems and emerging health needs." Surgeon General Leroy Burney conceded that there are some problems in financing the care of the aged but there may be need first for more emphasis on facilities, personnel, and administration. He cited the fact that the federal government had spent over 1 billion dollars on Hill-Burton facilities yet had expended only a little over 1 million dollars for research on facilities for various groups of patients.

Spokesmen for the American Medical Association (headed by President Gunnar Gundersen), Blue Shield, American Hospital Association, and Association of Methodist Homes and Hospitals told of numerous voluntary efforts and studies designed to solve problems of financing oldsters' medical and hospital costs. Ray Amberg, president of the A. H. A., told the conference: "We hope to solve this problem without federal aid." He had in mind bills for providing free hospital and medical care for social security beneficiaries.

Dr. Ernest B. Howard, assistant executive president of the American Medical Association, said it would be "disastrous to jump into a full program so radical" as the social security proposal. In reply to a question, he added that there was a definite neeed for government research in this field.

The need for a higher level of self-care of older people was cited by the spokesman for the Methodist homes.

CONSULTANTS STUDYING PROBLEMS OF MEDICAL EDUCATION

A committee of advisers to Surgeon General Burney is at work attempting to find an answer to the question: "How can the nation be supplied with adequate numbers of well-qualified physicians over the next decade?" The group's organization meeting was held Dec. 8 in Washington, D. C.

The new body is the outgrowth of a plan announced by Dr. Burney in October when he addressed the American College of Surgeons in Chicago. In announcing appointment of 17 members (with four to be named later), Dr. Burney said it would not be "just another study" of medical manpower, a reference to the many federal investigations and reports on this subject in the last few years. He said the consultants themselves would determine the scope of their study and methods of operation, but he suggested five possible approaches:

"Appraise existing data, plans, and proposals related to medical schools and the nation's needs for physicians.

"Identify areas of agreement and areas that require further study.

"Recommend general actions which might be taken to achieve reasonable and acceptable goals in medical manpower over the next 10 to 20 years.

"Recommend any specific actions which educational institutions, foundations, industry, local, state, and federal governments should take in meeting these goals.

"Recommend the proper role, if any, that the Public Health Service should play and the steps which it should take."

In his letters of invitation, Dr. Burney emphasized that "whether there is an absolute or relative shortage of physicians, the need for physicians will increase in the immediate future." He said the Public Health Service is concerned, as are the medical and allied professions, the leaders in education, and the public. He declared that PHS is aware of specific need for more physicians by research institutions, hospitals, state and local governments, health agencies, and industry.

Appointment of the committee, following a warm reception in the Department of Health, Education, and Welfare for the Bayne-Jones report and talks on the subject by the top officials of the department, is evidence that the administration next year will be prepared to push for enactment of some federal plan for financial assistance to medical schools.

The Bayne-Jones report proposed a tripling of the nation's spending for medical research in the next 12 years, and immediate start on between 14 and 20 new medical schools.

Chairman of the consultants group is Frank Bane, former executive secretary of the Council of State Governments. He has been active in public affairs for more than 30 years. The 17 appointments announced are:

Ward Darley, M.D., Executive Director, Association of American Medical Colleges; Edward L. Turner, M.D., Secretary, Council on Medical Education and Hospitals, American Medical Association; Edwin L. Crosby, M.D., Director, American Hospital Association; Miss Marion W. Sheehan,

Associate General Director, National League for Nursing; Harold Hillenbrand, D.D.S., Secretary, American Dental Association; Vernon W. Lippard, M.D., Dean, School of Medicine, Yale University; Dr. Harold L. Enarson, Executive Director, Western Interstate Commission for Higher Education, Boulder, Colo.; John McK. Mitchell, Dean, School of Medicine, University of Pennsylvania; Isidor S. Ravdin, M.D., Vice-president, Medical Affairs, University of Pennsylvania; Emory W. Morris, D.D.S., LL.D., President, W. K. Kellogg Foundation, Battle Creek, Mich.; Mr. Douglas E. H. Williams, Executive Secretary, Dunbar Community Association, Inc., Ann Arbor, Mich.; Morris Thompson, ScD., President, Kirksville College of Osteopathy and Surgery, Kirksville, Mo.; Julian P. Price, M.D., A. M. A. Trustee, Florence, S. C.; Fred C. Cole, Ph.D., Academic Vice-president, Tulane University; Clayton G. Loosli, M.D., Dean, School of Medicine, University of Southern California, Los Angeles; and Charles E. Smith, M.D., Dean, School of Public Health, University of California, Berkeley, Calif.

U. S. MAPS CAMPAIGN AGAINST AIR POLLUTION

As a follow-up on the National Conference on Air Pollution, the Department of Health, Education, and Welfare has announced plans for legislative proposals, stepped-up research, and formation of a study group, all aimed at combatting air pollution.

Secretary Flemming outlined first what he described as a constructive step in dealing with interstate air pollution problems. Congress should give consideration to allowing the federal government to hold hearings and make findings and recommendations where interstate problems are involved, he said.

The Robert A. Taft Sanitary Engineering Center at Cincinnati is launching a number of research studies in the auto exhaust problem. They include (1) construction of two irradiation chambers which will study the action of sunlight on automobile exhausts as basis for determining health effects of irradiated gases, (2) starting after the first of the year animal experiments on the effect of auto exhausts, and (3) studies using precise measurements of effects of exhaust on plants and bacteria.

A third development will be calling together of a group representing industry, state and local governments, universities, and other research groups. Their job would include working out practical methods of carrying out conference proposals in medical and engineering research. They also will be asked to indicate what should be a "fair share" for federal, state, and local governments and for industry and other private groups.

NATION'S MILK SUPPLY CONTINUES FREE OF DANGEROUS RADIATION

Despite continuation of nuclear weapons testing, the nation's milk supply still does not have a dangerously high level of radioactivity.

This is the report from Public Health Service, based on tests made during August at 10 sampling stations scattered across the country.

A decline in strontium-90 levels, as compared with July testing, was recorded in milksheds serving Austin, Cincinnati, Fargo, N. D., New York City, Salt Lake City, and St. Louis, Mo. Slight increases were reported for milksheds serving Atlanta, Chicago, and Sacramento, Calif.

Tests for four other specific radioactive elements in milk—iodine-131, strontium-89, barium-140, and cesium-137—showed variations not only among sampling stations but also among samples taken from the same stations. However, in no case was a permissible level exceeded.

Samples are analyzed at the PHS Robert A. Taft Sanitary Engineering Center at Cincinnati. The operation takes more than six weeks.

QUALIFICATIONS TO BE EASED FOR FOREIGN DOCTORS

After a year's experiment, the group in charge of examining foreign-educated physicians for internships and residency appointments has decided to set up a "provisional qualification" for applicants who come within five points of the passing grade of 75.

Dr. Dean F. Smiley of Evanston, Ill., executive director of the Educational Council for Foreign Medical Graduates, made a progress report on the new program at the clinical session of the District of Columbia Medical Society. He presented this information:

In the first tests last spring, 298 applicants were examined. Of these, 152 (51%) made passing grades of 75 or better and another 50 (17%) rated between 70 and 74. The most recent examinations, in September, found 318 of the 844 applicants passing and 225 scoring 70 to 74. Next examinations are scheduled for February, with 2,300 applications already received.

Under the new procedure, those finishing between 70 and 74 will be allowed to take internships or residencies for two years. After this period they may take the examination again if they wish to stay in the United States longer.

Objective of the testing program, Dr. Smiley explained, is to guard against medical imposters, cult practitioners, and other untrained or inadequately trained foreign medical graduates being admitted to American hospitals and American medical practice.

Dr. Smiley said one of the developments of the last year was the effort of a number of foreign countries to induce their nationals to return when they had finished their internships and residencies, rather than take up medical practice in the United States.

MISCELLANY

Most recent tabulation by the Housing and Home Finance Agency shows a total of almost 2 million dollars in loans awarded for projects in the health fields. They are $550,000 for a water distribution system in the Good Hope, Calif., area; $277,000 for a water system in Wood River Township, Ill.; $40,862 to plan a sewage disposal system in Pen Argyl, Pa.; $563,000 to help build a student nurse dormitory at Albany Hospital, Albany, N. Y.; and $366,000 to help finance a student nurse dormitory at Children's Hospital, Columbus, Ohio.

COMPLICATIONS OF ENDOTRACHEAL INTUBATION

William Hamelberg, M.D., C. Merle Welch, M.D., John Siddall, M.D.
and
Jay Jacoby, M.D., Columbus, Ohio

Complications occurring after endotracheal intubation for general anesthesia were studied in 1,932 patients with special reference to the possibility of reducing postintubation symptoms by the topical use of hydrocortisone. This was added to the lubricant applied to the endotracheal tube in 322 patients. They were compared with 734 patients who received the lubricant without the hydrocortisone. A similar comparison was made between 670 patients who received the hydrocortisone topically in an aqueous medium and 206 patients who received the same medium (by spraying into the oropharynx and by instillation into the trachea) without the hydrocortisone. No serious complications occurred in any of these patients. Complaints referred to the throat, when endotracheal intubation could be the only source for complaint, were spontaneously mentioned by 28% of the patients, and questioning elicited such complaints from an additional 17%. No significant difference was found between the patients who received hydrocortisone and those who did not.

INTUBATION of the trachea is a procedure of great value. It provides assurance of a clear airway and prevents the entry of foreign material into the tracheobronchial tree. Many advances in both surgery and anesthesia have been made possible by its use. Because the technique is so valuable, this study was conducted to determine the frequency with which intubation results in complications and whether the incidence of complications could be decreased.

Among the factors which may limit the use of endotracheal intubation are complications due to the inexperience of the anesthetist and those due to the presence of the foreign body. Prolonged induction, trauma, and hypoxia during attempts to intubate have largely been eliminated as increasing numbers of skilled anesthetists have become available. The rapidly acting anesthetic and muscle relaxing agents permit the skilled operator to induce anesthesia and to insert the endotracheal tube in a minimum of time and without trauma. Coughing and straining after intubation can be minimized, and bacterial contamination need not be a major problem. The use of a local anesthetic by spray, transtracheal injection, or in the lubricant on the endotracheal tube reduces the depth of anesthesia required for tolerance of the tube. The late post-

Read before the Section on Anesthesiology at the 107th Annual Meeting of the American Medical Association, San Francisco, June 26, 1958.

operative complications, principally laryngeal granulomas, are quite rare and are not a significant deterrent to the use of the technique.

The complications of most concern to the patient, the surgeon, and the anesthetist are those which may be manifest during the first few days after intubation. These may be caused by trauma, infection, edema, and inflammatory reaction. The patient notices symptoms which include difficulty in swallowing, sore throat, hoarseness, and aphonia. On rare occasions, the anatomic changes may be so great as to cause respiratory obstruction and require tracheotomy for relief. Such serious reactions occur more often in children than in adults and may be associated with infection or a tightly fitting endotracheal tube.

There are many articles which call attention to the alarming consequences of intubation and occasional fatalities. The latter, fortunately, are very rare. The incidence of complications ranges from 1.6 to 100%.[1]

TABLE 1.—*Age Distribution of Patients Who Underwent Endotracheal Intubation*

Age, Yr.	Treatment with Hydrocortisone, No.	Controls, No.	Total
5-9	6	28	34
10-19	49	82	131
20-29	112	141	253
30-39	155	164	319
40-49	178	167	345
50-59	216	155	367
60-69	192	149	343
70-79	69	48	117
80-89	13	10	23
Total	992	940	1,932

Among the considerations in the prevention of complications are the use of sterilized tubes and the avoidance of trauma, excessively large tubes, irritation by chemical sterilizing agents, and allergic reaction to lubricants.[2]

Interest in a possible means of reducing the incidence of complications was aroused after an experience with a difficult case. The patient was an elderly woman who had had a somewhat traumatic intubation for a laparotomy and who developed hoarseness, sore throat, and mild respiratory obstruction in the postoperative period. At the time when these symptoms were at their height, she developed a dehiscence. Because she had just eaten lunch and because she refused regional anesthesia, endotracheal intubation was mandatory for the second operative procedure. Anesthesia, intubation, and operation were uneventful. An attempt was made to prevent further laryngeal edema by the use of hydrocortisone as a preoperative laryngeal spray and by postoperative inhalation of a nebulized solution. The results were gratifying in that her already existing symptoms did not become worse; on the contrary, they disappeared more rapidly than expected.

Since one of the principal actions of hydrocortisone is the reduction of edema and inflammatory reaction, it was postulated that this substance might be useful in preventing the complications which follow endotracheal intubation.

Method of Study

Two groups of patients were studied, comprising most of the patients who had intubation during one-year period. Not included are patients i whom intubation was done when the recover room was closed (since the records were kep there) or who left the hospital before a postoperative interview could be obtained. The endotracheal tubes were of the red rubber variety. After use, the tubes were washed with hexachlorophene (pHiso-Hex) and water and then autoclaved and stored on open shelves. They were considered to be clean but not sterile at the time of their next use. Intubation was done by about 30 individuals ranging in skill from beginning residents to senior staff. MacIntosh laryngoscopes were used in almost all cases.

The total number of patients in this study was 1,932. Male and female patients were approximately equal in number. The majority of patients were between the ages of 20 and 70 years. The age distribution is indicated in table 1.

In the first group, comprising 1,056 patients, hydrocortisone was used in a 1% concentration in a 5% lidocaine (Xylocaine) hydrochloride ointment; this was applied to the endotracheal tube before insertion. In the second group, comprising 876 patients, a 2% solution of hydrocortisone in isotonic sodium chloride solution was used. Two cubic centimeters was instilled into the trachea prior to the removal of the endotracheal tube and 3 cc. sprayed into the oral pharynx with a no. 15 DeVilbiss atomizer. In each group, control studies were carried out with use of similar ointment or isotonic sodium chloride solution without the addition of hydrocortisone.

The patients were visited daily for the first three days or longer by a single individual in the first study and by two individuals in the second study. None of the personnel associated with intubation, instillation of solution, or postoperative visits was aware of the nature of the material which was used for any patient. The data obtained were recorded on mimeographed sheets and transferred to IBM cards, which were then sorted into control and experimental categories.

During the postoperative visits in the lubricant study, the patients were not specifically informed of the study or questioned about their symptoms. During the interviews, there were general conversations regarding the patients' physical condition. If a patient volunteered that he had symptoms referable to his throat or his voice, detailed questions were asked about the nature of the difficulty. In the hydrocortisone solution study, patients were informed that intubation had been done and were specifically asked about any symptoms referable to the throat or the voice.

Results

Predisposing Causes.—There are many reasons why patients might have symptoms referable to the throat. Some had preexisting upper respiratory infection with cough, sore throat, hoarseness, or sinusitis. Many had symptoms from the nasogastric tube inserted prior to surgery. Many had operative procedures in adjacent areas, including tonsillectomy, thyroidectomy, neck dissection, and other operations within the oral or pharyngeal cavities. Three of every five patients had these predisposing causes for symptoms referable to the throat. Among these, symptoms arose in 53%. Among the patients who did not have predisposing causes, symptoms arose in only 37%.

Influence of Direct Questioning.—In order to obtain more significant information about the incidence of postintubation symptoms, the patients were divided into categories of those who had predisposing causes and those in whom the endotracheal intubation was the only obvious cause for symptoms.

Twenty-eight per cent of the patients who were not questioned specifically about their throat or voice (the lubricant group) mentioned that they had symptoms. Forty-five per cent of the patients who were informed that intubation had been done and who were questioned about symptoms (the solution group) gave positive replies. A similar difference occurred in the control group; 35% complained spontaneously and 49% complained if asked (table 2).

Effect of Hydrocortisone.—Among the patients who had predisposing causes for symptoms referable to the throat, the use of hydrocortisone either in the lubricant or in the solution made little difference in the incidence of symptoms. Among those patients who had no predisposing cause for symptoms, the use of the hydrocortisone solution made little difference. When the hydrocortisone lubricant was used, however, the incidence of symptoms after intubation diminished from 35 to 26% (table 3).

Table 2.—*Incidence of Postintubation Symptoms in Patients with No Predisposing Causes*

	Route of Intubation	Patients, No.	Symptoms Present	
			No.	%
No leading questions (lubricant group)	Oral	346	93	27
	Nasal	90	26	29
Total		436	119	28
Leading questions (solution group)	Oral	243	106	42
	Nasal	206	100	48
Total		449	206	45

Other Interesting Findings.—There was no difference in the incidence of symptoms for patients intubated by first-year residents, second-year residents, or staff anesthetists. This was probably due to the fact that most intubations done by the staff were those which the residents were unable to complete because of inexperience or technical difficulty. Patients in whom intubation was done by staff members, therefore, had already been subjected to some degree of trauma. For the entire group, easy intubation was followed by symptoms in 45% of the patients, whereas difficult intubation was followed by symptoms in 54% of the patients.

Table 3.—*Influence of Hydrocortisone on Postintubation Symptoms*

	No Predisposing Causes			Predisposing Causes		
	Patients, No.	Symptoms Present		Patients, No.	Symptoms Present	
		No.	%		No.	%
Hydrocortisone lubricant	148	38	26	171	72	41
Control lubricant	288	81	35	446	206	46
Hydrocortisone solution	331	150	45	339	223	66
Control solution	118	58	49	88	55	63

The route of intubation had some bearing on the incidence of symptoms. Nasal intubation tended to be used more often with patients who had operations on the neck and within the throat. Since these operations predispose to the development of symptoms, disproportionate figures are obtained if only these patients are considered. Table 2 indicates the incidence of symptoms and the routes of intubation in those patients who had no predisposing causes. In the lubricant study, all routes of intubation produced approximately the same proportion of symptoms. In the solution study there were symptoms in 48% of patients in whom nasal intubation was done and in 42% in whom the oral route was used.

Comment

How often do symptoms develop after endotracheal intubation? Some surgeons believe that every patient with a sore throat after operation has it because of the intubation. It has been found in some instances that a sore throat is ascribed to intubation even when intubation has not been done.

There is a wide divergence in the reports of incidence of complications. This, of course, stems from the fact that various observers do not use the same criteria in determining whether a complication exists. In this study, the factor of individual variability in interpretation was kept to a minimum by having all interviews conducted by a single individual in one group of patients and by two individuals in the other group. In addition, no effort was made to eliminate slight, as compared to moderate, degrees of discomfort. Had the postoperative observations been carried out by the persons who actually performed the intubation, about 30 different observers would have been involved.

Patients who were already complaining about sore throat and hoarseness when they arrived in the operating rooms, or whose operations would normally produce such symptoms regardless of whether intubation was done or not, comprised over half of the entire series (61%). Three of every five patients either had, or might be expected to get, symptoms regardless of whether intubation was done. These individuals had a higher incidence of postoperative symptoms (53%) than the others (37%).

The incidence of symptoms after intubation in this study is probably higher than would be encountered in nonteaching institutions. In particular, the incidence of symptoms after nasal intubation is higher because many of the workers were just learning the technique and it was used to a large extent for head and neck surgery.

It is important that in practically all patients the symptoms were an annoyance rather than a significant complication. Many patients were troubled so little that they did not mention the symptoms unless specifically asked about them. When the patients were informed that intubation had been done and when they were specifically questioned about symptoms referable to the throat, the number of complaints significantly increased (45% compared to 28%). Differences of similar magnitude appear between the control groups in which no medication was used (table 3). Neither signs nor symptoms of respiratory obstruction occurred in any patient. Severe respiratory obstruction due to intubation is so rare in adults that in this institution during the past 11 years tracheotomy has not been required.

The use of hydrocortisone topically, by instillation into the trachea, by spray into the pharynx, or as a lubricant on the endotracheal tube produced no statistically significant change in the incidence of symptoms. Hydrocortisone solution is rapidly absorbed from mucous membranes. In a lubricant on the endotracheal tube, the topical effect is also rather brief. When applied in this way, however, there was a reduction in the incidence of symptoms from 35% to 26%. Although not statistically significant, this suggests that more prolonged topical application of hydrocortisone might have a more marked effect. Further studies are planned with more prolonged topical application.

Summary

The topical use of hydrocortisone has been studied as a means of reducing postintubation symptoms referable to the throat. No statistically significant changes in the incidence of symptoms followed the topical application of hydrocortisone

Predisposing causes for symptoms referable t
the throat were present in 61% of patients in whon
intubation was done. Almost two-thirds of the pa
tients who developed symptoms in the postoperativ
period had factors other than intubation which ma
have been responsible. These included preexistin
respiratory infections, nasogastric tubes, and opera
tions in the area.

No serious complications were encountered i
more than 1,900 intubations. In many instance
postintubation complications were so mild that p
tients did not mention them. The presence of sym
toms was stated voluntarily by 28% of patients;
response to questioning 45% of patients gave
affirmative reply.

This study was supported by a grant from the Upjo
Company.

HAZARD OF CARBON DIOXIDE.—Two instances of severe reactions to high concentrations of carbon dioxide re-emphasize the fact that this gas can be dangerous because it produces effects rapidly and is more than a simple asphyxiant. These incidents involved near-collapse of aircrew members on a cargo aircraft transporting frozen foods with 12,000 and 7,400 pounds of dry ice, respectively. Some countries require that dry ice transported in aircraft be in a closed container vented to the outside. A more practical approach is being made by the Military Air Transport Service through the utilization of industrial hygiene engineering studies to determine safe dry ice loadings for all type aircraft based on a threshold limit value of 0.5 per cent carbon dioxide.—Col. J. B. Nuttall, Toxic Hazards in the Aviation Environment, *The Journal of Aviation Medicine*, September, 1958.

STERILITY AND INFERTILITY—MEDICAL VIEWS

Melvin R. Cohen, M.D., Chicago

Many of the factors involved in sterility are still unknown, but, when married couples desire children, diagnostic surveys are frequently successful. Careful diagnosis is essential to good treatment, but for some reason pregnancy sometimes follows the diagnostic survey before treatment is begun. Attention must be given to both partners. Each must have a physical examination, and laboratory procedures such as semen analysis may be necessary in addition to special procedures such as tubal patency tests and culdoscopy. The diagnosis, though sometimes difficult, occasionally reveals a situation that is obviously remediable by medicine or operation. The roles played by various hormones in pregnancy tests, in the induction of ovulation, in controlling sperm-production, and in preventing fetal wastage need to be better understood and more fully utilized.

Just as highly fertile couples desire methods of family limitation, so childless couples desire help for their infertility. The demand by the infertile couple for medical aid is growing, and, despite gaps in our knowledge of human reproduction, much can be achieved.

The stress of modern civilization has been blamed for the apparent high incidence of infertility. For the exact incidence of involuntary sterility, we must consult the demographers. Tietze[1] quotes Louis Henry (census of England and Wales, 1911) that, at the age of 20, 3% of wives are sterile; at the age of 30, 12%; and at the age of 40, 32%. Tietze in his study of the Hutterites showed that 1 in 10 ceased to reproduce at the age of 35, 1 in 3 by the age of 40, and 7 in 8 by the age of 45.

Guttmacher[2] showed that, in rural Quebec, Canada, where birth control probably is not used, the percentage of childless marriages increased with the age of the wife at the time of marriage. In the 25-29 year age group, for example, 10.2% of marriages were childless, and in the 30-34 year age group 16.2% were childless. He further reported that, even in fecund couples with planned pregnancies, 10% required more than a year to conceive.

Medically approved birth control measures will not induce sterility but will delay the possibility of conception to an older, less fertile age group.

In order to understand some of the problems of human infertility, let me review the physiology of reproduction and my diagnostic survey of the infertile couple.

Physiology of Reproduction

The physiology of reproduction is illustrated in figure 1. The anterior lobe of the pituitary gland secretes a hormone known as follicle-stimulating hormone (FSH). This hormone acts on the ovary to stimulate the growth of perhaps 10 or more follicles. For some unknown reason, all but one of these follicles become smaller and undergo certain changes, which are called atresia. The remaining follicle enlarges and becomes ripe (the graafian follicle).

Estrogen, elaborated by these follicles, acts on the lining of the uterus to produce a proliferative endometrium. The estrogen also acts on the endocervical glands to produce a clear, mucoid secretion which grossly resembles egg-white. Just prior to ovulation, the cervix, uterus, and fallopian tubes are filled with clear, mucoid secretion. Spermatozoa deposited at the upper end of the vagina at this time find easy access through cervical mucus into the uterus and up into the tubes. This clear passage enables fertilization to occur in the ampulla of the tube. Estrogen produced by the ovarian follicles acts on the anterior lobe of the pituitary gland to release luteinizing hormone (LH). LH then stimulates rupture of the graafian follicle with release of the ovum.

Ovulation in the living albino rat has been described and beautifully photographed by Richard J. Blandau. Ovulation was induced in immature rats by giving gonadotropin. In his work, the first indication of approaching ovulation was the formation of the macula pellucida, or stigma, which usually appeared at the apex of the follicle. This stigma forms within a few seconds to several minutes. As rupture of the follicle becomes imminent, the superficial germinal epithelial cells, which cover the stigma, may be observed breaking up into small clumps. The time required to extrude the egg varied according to the position of the cumulus oophorus within the follicle. All ovulations that could be seen in a particular ovary were completed in less than an hour and a half. Often, several follicles ruptured at the same time. Hemorrhage was minimal in most ovulations. In Blandau's magnificent film, he showed how readily the fimbria of the tube seemed to swallow these ova, which were colored by means of a vital dye.

From the Division of Obstetrics and Gynecology and the Department for Research in Human Reproduction, Michael Reese Hospital.

Read before the Population Association of America, Chicago, May 4, 1958.

Ovulation in the human has been observed by but a few men. Decker,[3] who invented the culdoscope or transvaginal peritoneoscope, described ovulation occurring as follows: the fimbria of the tube would apply itself to the follicle and would remain attached for several minutes until the egg was extruded from the follicle into the tube. When the fimbria of the tube fell off the ovary, the ovary became transformed and contained a corpus hemorrhagicum.

Doyle,[4] by means of a different technique, that of culdotomy (using a different type of instrument through a much larger opening in the vagina and with the patient under prolonged general anesthesia), has described and photographed ovulation occurring without the exact attachment of the fimbria of the tube to the ovary.

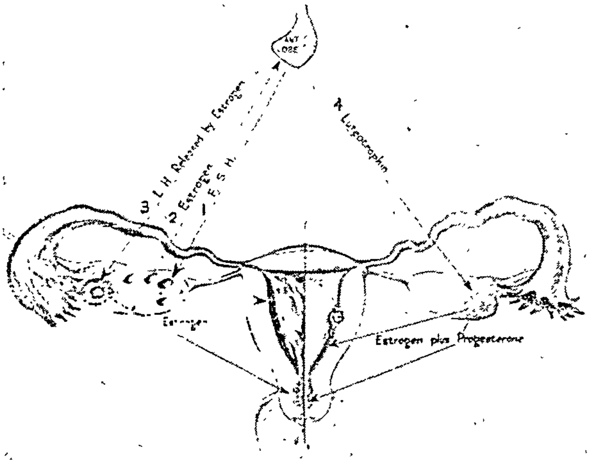

Fig. 1.—Physiology of reproduction.

During one isolated instance at culdoscopy, I observed ovulation occurring as follows: the fimbria of the tube became attached to the lateral aspect of the ovary and remained there for several minutes. After this, the follicle that had been present prior to the attachment immediately was transformed into a corpus hemorrhagicum. Therefore, I was able to confirm Decker's original findings.

After ovulation and extrusion of the egg into the tube, the anterior lobe of the pituitary gland secretes a third gonadotropic hormone, known as prolactin (Luteotrophin). This maintains the corpus luteum. When seen early after ovulation, this corpus luteum occupies from one-third to one-half of the ovary and is intensely red, with a number of blood vessels coursing into it. The area of rupture may be represented by a small blood clot or coagulum, or it may be represented by a thin membrane. When seen about the 15th to 17th day, it has the appearance of an intensely blood-shot eye, "the eye of the corpus hemorrhagicum."

The corpus luteum secretes both estrogen and progesterone, which then act on the proliferative endometrium, converting it to a secretory endometrium or glycogen-containing membrane, into which the fertilized egg can be implanted. Estrogen and progesterone also act on the cervical mucus to thicken it, so that spermatozoa cannot now penetrate into the uterus easily. Fertilization itself takes place in the ampulla of the tube, and the fertilized egg takes several days for its passage into the uterus.

Apparently, tubal epithelium plays an important part in the early stages of cell division. Landrum B. Shettles has been able to develop follicular eggs in vitro. With a large-gauge needle, he taps a mature follicle to obtain an ovum from the ovary in a patient at laparotomy. The ovum and follicular fluid are discharged into a sterile Petri dish, to which a drop of fresh human semen and some minced fragments of mucosa from the fallopian tube are added. Tubal mucosa is used because of evidence that its fibrinolytic enzyme system is important to denudation of the ovum and its subsequent penetration by the spermatozoon. When incubated, the ovum grows to as much as a 32-cell or Morula stage. When actual implantation takes place in the human, the egg is implanted in the blastocyst stage.

Conception, therefore, depends on (1) fertile spermatozoa, (2) receptive secretions in the female, (3) open fallopian tubes, (4) ovulation, (5) good corpus luteum function, and (6) an adequate endometrial response for good implantation of the fertilized egg.

Diagnostic Survey

The wife usually consults her doctor first. However, it is always preferable for both husband and wife to be interviewed before any diagnostic survey is attempted, in order that full understanding and cooperation are obtained from both. In the initial interview, the physician must gain some insight into the emotional needs of the couple. He must determine whether their marriage is secure. Their desire for a child must not merely be an attempt to patch up an unhappy marriage.

The following points should be covered in the initial interview of the couple: (1) length of marriage, including prior marriage of either partner; (2) infertility—primary, secondary, and duration; (3) birth control—duration; (4) conceptions; (5) abortions; (6) previous diagnostic studies; (7) coital history, including frequency, techniques, difficulties, dyspareunia, and frigidity; (8) menstrual history, including leukorrhea; and (9) general history of each partner, including medical, surgical, and nutritional history in childhood, adolescence, and adulthood. A general physical examination of each partner, with genital examination of the husband and pelvic examination of the wife, and general laboratory examination of both partners should also be done.

Semen Analysis.—The actual survey of the infertile couple usually begins with semen analysis, unless the couple present themselves near ovulation time. In that case, it is more rational to observe the effect of spermatozoa in vivo in the female, rather than obtaining a bottle specimen at such a time. Although, theoretically, it only takes one normal, motile spermatozoon to achieve conception, a highly fertile male will have millions of actively motile spermatozoa present in his ejaculate. A sterile semen specimen contains no spermatozoa (azoospermia); few spermatozoa (oligospermia); or all dead spermatozoa (necrospermia). There are vast variations and degrees of fertility, as shown by semen analysis. Gross characteristics include a volume range of 2 to 8 cc. (average, 3.5 cc.), cloudy and whitish fluid, and minimal viscosity. Many times multiple examinations must be done, as there are variations in sperm count (average normal, 40-60 million per cubic centimeter), motility (60% or more motile, with majority showing good forward progression and 8-24 hours' longevity in vitro), and perhaps even morphology (70% or more normal).

In figure 2, variations in semen quality are presented. Motility, as observed in a fresh thin smear, is more important than actual number of spermatozoa. The stained smear is very useful in evaluating semen quality, but the interpretation of abnormal spermatic morphology requires training and experience. The clumping phenomenon, as illustrated, can also be demonstrated in the fresh smear. Clumping of spermatozoa is frequently seen in the ejaculates of infertile males.

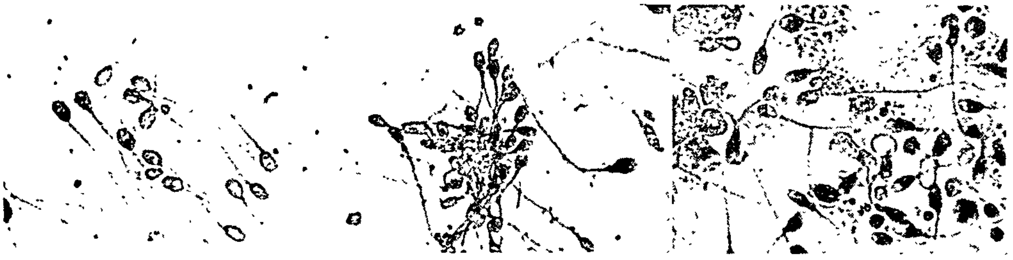

Fig. 2.—Variations in semen quality; *left,* normal spermatozoa; *center,* clumping phenomenon; *right,* highly abnormal sperm population (hematoxylin, rose bengal; × 1,500).

Clinical Evidence of Ovulation.—Pregnancy, of course, is the best evidence of ovulation. Although the ovum is the largest cell in the body, it cannot be found except experimentally by washing out the fallopian tubes. All tests of ovulation are clinical or subjective. They are chiefly the result of the cyclic effects of estrogen and progesterone.

The wife is instructed to take her basal body temperature, rectally if possible, each morning before arising, beginning shortly after her menstrual period is over and continuing daily until menstruation ensues. A typical basal temperature chart is illustrated in figure 3, with the low point of the temperature on the 12th day and a sustained elevated temperature curve from the 14th to 27th day. Should pregnancy result, this elevated temperature will be sustained well beyond the time of the first missed period.

Other associated phenomena are indicated above this basal temperature chart (fig. 3). These include the rat test for ovulation,[5] vaginal smears for evidence of cornification, and quantity and quality of cervical mucus. Below the basal temperature chart, one may note the endometrial biopsy on the last day of the cycle (the first day of the menstrual period), as well as the endometrial biopsy on the 21st day, when glycogen secretion is maximal. The 24-hour daily urine excretion of pregnanediol, a metabolite of progesterone, is also shown.

This typical patient is instructed to report to the office daily from the 10th to 14th day of the cycle. The day of the cycle is counted from the first day of the menstrual period. A vaginal speculum is inserted, without lubrication, and the routine is as follows:

A small amount of vaginal secretion from the vaginal fornix is plated on a glass slide, immediately immersed in equal parts of alcohol and ether according to the method of Papanicolaou, and stained by means of the rapid Schorr stain.

The tip of a glass cannula is inserted into the endocervix, and, by means of gentle suction, a quantity of endocervical mucus is obtained for examination. This is blown out on a glass slide, and an estimation of the amount from 0 to 4+ (profuse) is made. A glass cover slip is then placed on this glob of mucus and the spinnbarkeit or stretch phenomenon measured in centimeters. The cover slip is then replaced, and the slide examined for the presence of white blood cells and spermatozoa. The cover slip is then removed, the mucus allowed to dry, and the fern phenomenon or crystallization of cervical mucus is observed.

Note the variation from the 10th to the 14th day of the cycle (fig. 3). It is believed that ovulation occurs either at the low point in the temperature cycle, the day before this low point, or on the rise from low to high. Prior to ovulation, the cervical mucus becomes profuse, thin, acellular, and stretches from 10 to 15 cm. Normally at this time, large numbers of spermatozoa are recovered postcoitally. The vaginal smear will show gradations of increasing cornification. After ovulation occurs, the temperature becomes elevated and sustained; the cervical mucus becomes scantier and thick and shows very little stretch. The vaginal smear exhibits curling and clumping of cells, or the so-called ex-

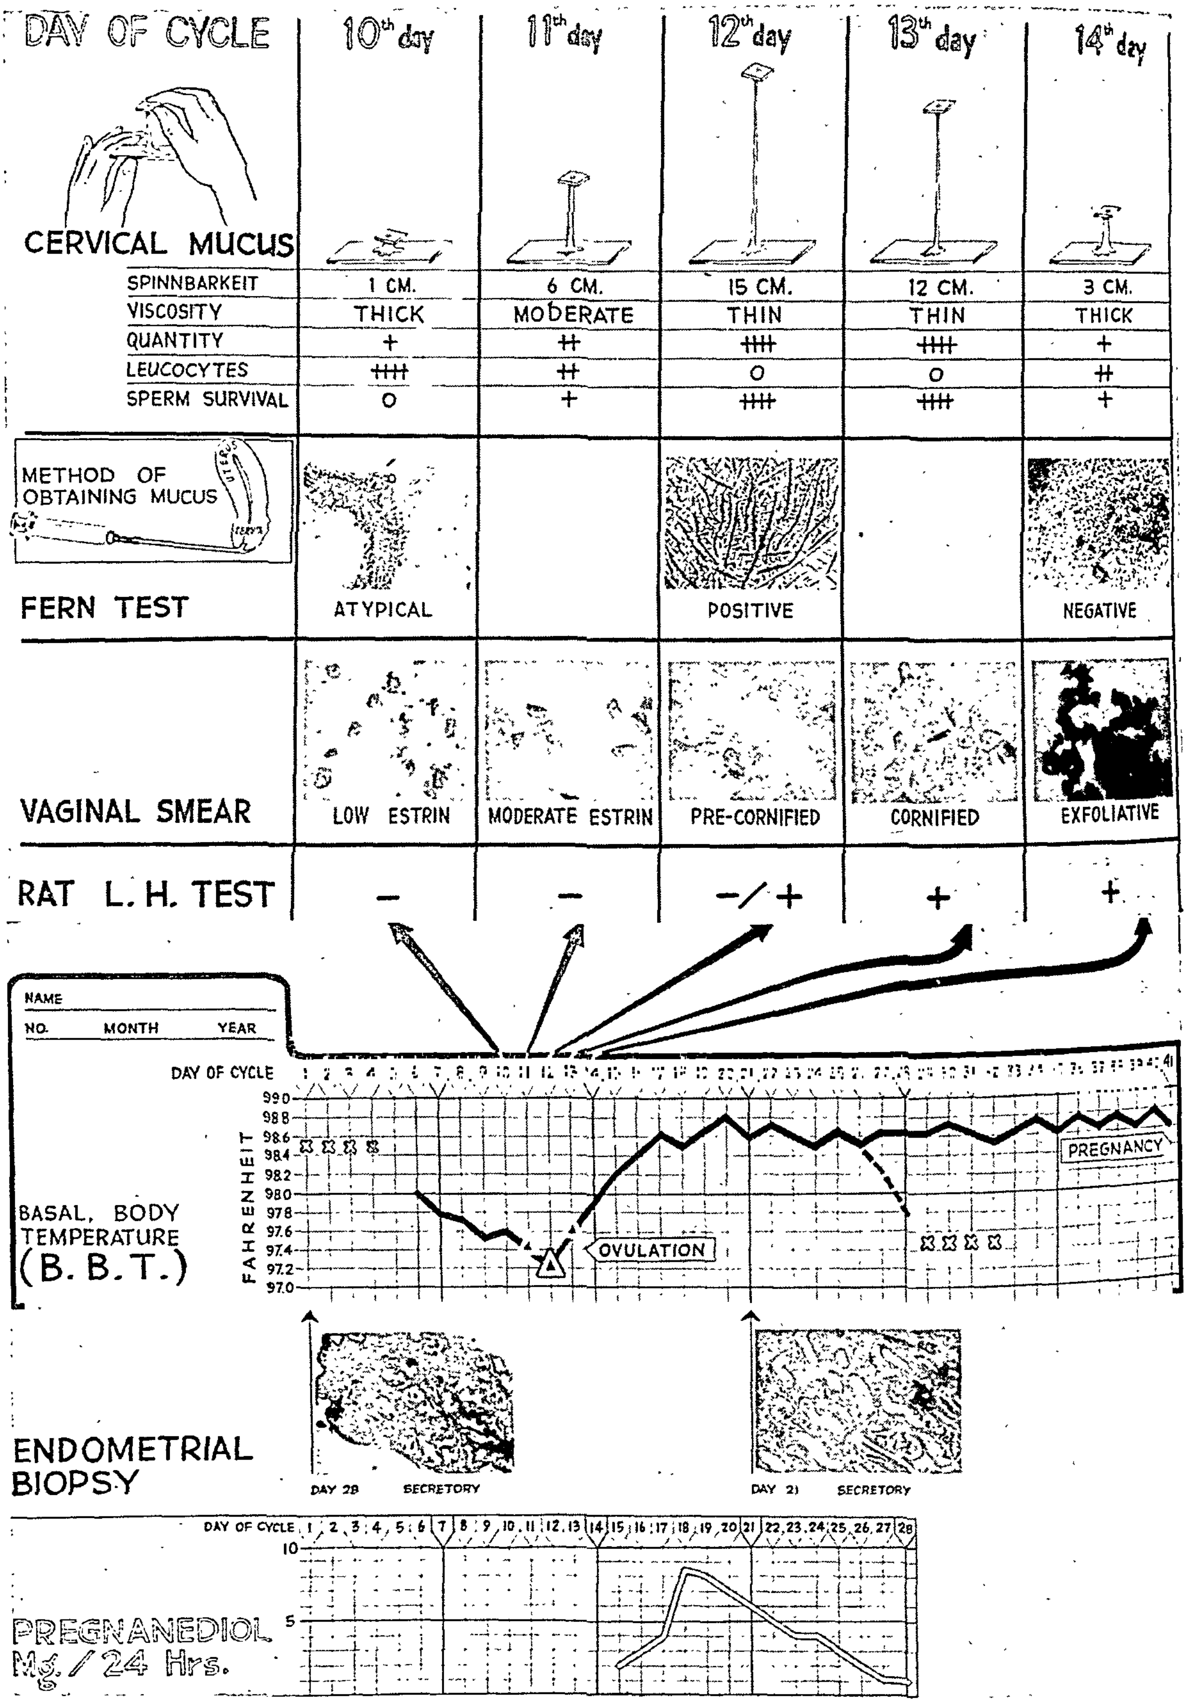

Fig. 3.—Typical charts, with biopsies, showing presumptive evidence of ovulation.

foliative phenomenon. The fern test does not show changes as critical as the vaginal smear, cervical mucus, and basal body temperature graphs.

The rat test for ovulation should prove valuable when the other simpler criteria for ovulation are absent or atypical. The technique of the test is as follows: 3 cc. of the first morning urine is injected intraperitoneally into each of two 50-to-60-Gm. immature female rats, and the rats are sacrificed in four hours; a positive reaction is cherry red hyperemia in one or more of the rats' ovaries. Preliminary experiments in this laboratory indicate that the rat test is positive on the day of maximal spinnbarkeit, as well as on the following day, as indicated on days 13 and 14 in figure 3.

The endometrial biopsy showing secretion in the gland lumina indicates that ovulation probably has taken place but does not indicate the time of ovulation except in retrospect.

Small quantities of pregnanediol may begin to appear in the urine prior to ovulation, but it is chiefly found in the premenstrual phase of the cycle. It must be noted that ovulation can occur with poor corpus luteum function, as indicated by short or atypical diphasic curve on the basal body temperature chart, endometrial biopsy showing poor secretory function, or diminished pregnanediol excretion, resulting in infertility.

Fig. 4.—Tubal patency test, pneumoperitoneum, and culdoscopy.

Tubal Patency Tests (fig. 4).—In 1919, Dr. I. C. Rubin made a revolutionary discovery in the field of infertility when he devised a simple method of establishing whether or not the fallopian tubes are open. The technique is as follows: An intrauterine cannula is inserted through the cervix into the lower part of the uterus. By means of a source of carbon dioxide, and a method of controlling the flow of the gas at low levels, it is possible to establish tubal patency. Typically, the flow of gas rises to a pressure of about 100 mm. Hg and then drops suddenly to a level of 70 or 80 mm. Hg, oscillating at this level. When one listens to the lower part of the abdomen, bubbles of gas are heard to escape from the fimbriae of the tubes. Finally, at the conclusion of the test, when the patient assumes the erect position, the gas so introduced into the peritoneal cavity rises beneath the diaphragm, producing referred pain in one or both shoulders.

An alternate method of establishing tubal patency is performed by utilizing an opaque medium, such as iodized oil or an iodized aqueous medium, which casts a shadow on an x-ray film. This latter method not only is useful in establishing tubal patency but also is useful in delineating the size, shape, and position of the uterus.

Pneumoperitoneum and Culdoscopy.—Refinements in diagnostic techniques involving the female include pneumoperitoneum and culdoscopy. Pneumoperitoneum,[6] is a method of silhouetting the female organs by means of carbon dioxide. This may be combined with opaque mediums, and such a combined procedure has been called complete gynecography. This technique is useful in delineating ovarian cysts, fibroids, and other intrapelvic pathology. The x-rays in figure 4 demonstrate that more information can be obtained by the addition of carbon dioxide gas to the standard hysterosalpingogram. This technique requires special training.

Culdoscopy, or transvaginal peritoneoscopy, introduced by Alfred Decker, has become a valuable addition to diagnostic armamentarium in the survey of the infertile couple. It has made possible demonstration of ovulation or failure of ovulation. This procedure has been invaluable whenever the usual criteria of ovulation were atypical or absent. Culdoscopy is valuable also to establish the presence or absence of peritubal and periovarian adhesions, fibroids, endometriosis, and other barriers to fertility.

In the management of the infertile couple, culdoscopy is usually a final procedure useful in ruling out obscure pelvic pathology. Certainly for those women who have undergone an otherwise exhaustive survey, culdoscopy can be of paramount importance in determining whether they should continue treatment, institute adoption proceedings, or reconcile themselves to a childless marriage. In the older age group, culdoscopy has been used as a means of very rapid survey in order to conserve time. Frequently a final prognosis can be given after this examination. This technique, which requires special training, is illustrated at the bottom of figure 4.

Treatment of the Infertile Man

Treatment of the infertile man has been rather disappointing on the whole. However, general measures for the improvement of health and nutrition should be outlined. The husband should avoid overwork and stress. He should reduce his smoking to a minimum. Good diet and plenty of outdoor exercise are helpful. The gamut of vitamins from A to E have been given. Recently there has arisen an interest in the value of vitamin C to prevent clumping of spermatozoa. Thyroid or the newer triiodothyronine has been given with some benefit.

The normal hypothermia of the testes should be maintained. The patient should be instructed to wear a type of underwear that does not constrict or unduly warm the testicular region. Extremely hot baths should be avoided. The presence of a varicocele may be a factor, and a testicular support or surgical correction may be beneficial.

Testosterone rebound therapy[7] has evoked a great deal of interest. It has long been known that, when testosterone is given to the man, there will be a depression of the sperm count. When testosterone therapy is continued, not only will the sperm count become depressed but a complete azoospermia may be induced. However, when testosterone is then withdrawn, there will be a return to pretreatment levels or even an improvement in the spermatic picture. This so-called rebound phenomenon might show great promise, but it is a dangerous tool and should only be used in the hands of an expert. Testicular biopsies as well as frequent semen analysis are necessary to control such treatment.

Coital frequency and timing is another method of improving fertility. Certainly, if the exact time of ovulation can be ascertained, it would make good sense to instruct the couple to have coitus at that time. Further, if the time of ovulation can be predicted four or five days in advance, it would be advantageous to forbid coitus until the exact time of ovulation. However, the exact time of ovulation is still difficult to detect. Delaying coitus until ovulation had already occurred would be fruitless. Long periods of sexual continence will improve the total sperm count. Frequent coitus, though reducing sperm count, seems to improve the quality and motility of spermatozoa.

Treatment of the Infertile Woman

Treatment in the woman depends on improvement in general hygienic and nutritional factors, as well as correction of abnormal cervical, uterine, tubal, or ovarian factors, as outlined in the diagnostic survey. The diagnostic survey, in itself, is therapeutic, and many women will conceive during this survey. Especially significant is the patient who will conceive after improvement of the cervical factor or after tubal patency tests.

Cervicitis should be treated, if possible, with antibiotics rather than by cautery. Although cautery may cure an infected cervix, cervical glands are destroyed. This destruction of cervical glands diminishes the normal mucorrhea which occurs just prior to ovulation. Hostile or absent cervical secretions are major factors in the infertile woman. This hostile cervical secretion frequently may be improved with small doses of estrogen, such as diethylstilbestrol, 0.1 to 0.3 mg. by mouth daily.

Uterine retroversion, hypoplasia, and fibroids are rarely factors in infertility. Extreme uterine hypoplasia is usually part of an over-all underdevelopment of the female organs and is chiefly secondary to ovarian insufficiency—a condition difficult to improve.

The tubal factor has become less important with better control of gonorrhea and tuberculosis. Tubal obstructions may be treated medically, by means of repeated carbon dioxide patency tests under high pressures, to perhaps blow out the fimbriae of the tubes, as well as by surgical procedures. Surgical results have improved with the advent of finer techniques, antibiotics, and polyethylene tubing used as tubal splints. The over-all results[8] after tuboplasty operations, even those done by the best surgeons, statistically show less than 13% conceptions. Further, there will be an appreciable incidence of tubal pregnancies after such surgical procedures.

The treatment of failure of ovulation depends on adequate diagnosis. When bilateral polycystic ovaries are present, resection of both ovaries has been followed by about 66% good results, with resumption of menstruation, ovulation, and conception. This surgical approach to the so-called Stein-Leventhal syndrome has become a popular method of treatment.

Another popular method of treatment has been low-dosage x-ray therapy to the ovaries and pituitary gland. This method is also followed by approximately the same percentage of results as the surgical approach to the syndrome of bilateral polycystic ovaries. However, geneticists have warned about the danger of increasing the frequency of mutations from gonadal irradiation. Scientists in general have issued warnings against the hazards of using ionizing radiation for benign conditions.

Therapy with estrogens, which normally release luteinizing hormones and theoretically evoke ovulation, has been advocated by many clinicians. Estrogen has been given in very small doses as well as very large doses. Recently, the use of conjugated estrogens (equine), given intravenously,[10] has been advocated. It further has been suggested that, should a patient with amenorrhea and failure of ovulation be refractive to intravenously given estrogen, the physician is then dealing with the Stein-Leventhal syndrome and such a patient should have a bilateral ovarian resection. This logic is confusing to me, and, further, I have not been able to confirm the good results reported with intravenously given estrogen.

The cyclical administration of estrogens and progesterone also has its enthusiasts. The theory behind this type of medication is called "shaking of the clock." Perhaps after menses can be established artificially, the pituitary ovarian cyclical function will become reestablished and ovulation and menstruation will continue. Such treatment, however, is rarely helpful.

Cortisone preparations are useful drugs in the induction of ovulation in patients with adrenogenital syndrome.[11] Such women, with adrenal dysfunction, show elevation of urinary 17-ketosteroid excretion and may show some signs of masculinization, such as moderate to marked hairiness. The present choice of therapy is prednisolone, 30 mg. daily, gradually reduced to a maintenance dose of 10 mg. daily.

In the hypothyroid woman the employment of desiccated thyroid, thyroxine, or triiodothyronine may show spectacular results. These medicaments, unfortunately, are given too frequently to normal individuals without benefit.

The pituitary hormones, such as those extracted from animals or those used in combination with human chorionic gonadotropin, have shown no reliable effects in the human.

Artificial Insemination

The subject of artificial insemination in its entirety is beyond the scope of this paper. Artificial insemination may be divided into homologous or husband insemination and heterologous or donor insemination. Homologous insemination is indicated when there is faulty transmission of spermatozoa from the male to the female, due to impotence or premature ejaculation. Secondly, it is indicated when there is a severe cervical factor precluding sperm migration into the uterus.

Heterologous insemination, where no religious prohibition exists, is indicated in (1) absolute male sterility, (2) severe hereditary defects in the male, and (3) incompatibilities of blood type, both RH and ABO, with sensitization. The results of homologous insemination are poor. On the other hand, the results of heterologous insemination have been excellent.

Fast freezing, storage, and subsequent thawing of mammalian spermatozoa can be performed without impairing the fertilizing capacity. In animal husbandry, frozen semen has been successfully used for some years. Recently an interesting experiment was reported in the use of frozen human semen for insemination, with conception and delivery of normal children.[12]

Gaps in Our Knowledge

A method is needed for diagnosis of a fertile semen sample. Veterinarian colleagues say that the best test of bull semen quality is the percentage of conceptions after artificial insemination in a group of cows. This method of assaying semen quality in the human is untenable. Therefore one must rely on sperm counts, motility, and morphology. Certain standards of semen analysis have been set up, but it is still impossible to delineate absolutely a fertile specimen from an infertile one, unless azoospermia is present. Again, *there is no proof* of fertility except fertility itself. With an extremely poor ejaculate, a poor prognosis is given, but this is frequently in error. Recently I received the following letter:

> Last November and December, my wife and I were patients of yours with regard to our inability to have children during our five and one-half years of marriage. Our family physician . . . had sent us to you for examination and advice. Our last visit with you was around the first of December at which time you stated we had but a slight chance of becoming parents and should look into the possibilities of adopting a child. You suggested we revisit you in about six months for my wife did have some treatments and our case was not utterly hopeless.
>
> I am happy to report that my wife is pregnant, having conceived about the middle of December. I presume you do keep case histories and this may be of some interest and significance in your work.
>
> I should be interested to hear from you if you have any comments or explanations with respect to this, perhaps unexpected, pregnancy.

This is an example of an "unexpected" pregnancy which occurred in the same month that I had given a very poor prognosis. The prognosis was based on an oligospermia with poor motility. This conception occurred after an intensive survey of the couple, which concluded with an iodized oil x-ray examination of the wife.

Treatment of the infertile male needs great improvement. Perhaps part of the answer to this will be in prophylaxis against viruses and the proper management of undescended testes.

Induction of ovulation by means of a potent pituitary hormone is needed. Unfortunately, the human ovary is refractive to animal extracts. To be able to induce ovulation by means of a purified chemical LH principle would solve many problems in the induction as well as the timing of ovulation.

A better test of ovulation timing is also needed. Present tests are tedious and perhaps not too accurate. A new simple test for ovulation,[13] based on the detection of glucose in the cervical secretions, has been described. Should the value of this test be confirmed, it would replace the more complicated tests for ovulation. When patients ask me whether they are ovulating, I tell them that a woman does not ring a bell when she ovulates. Some years ago Burr and co-workers [14] demonstrated a sharp elevation of electrical potential simultaneously with ovulation in the rabbit. Perhaps with better electronic devices now available, this technique could be revived.

Pregnancy wastage in spontaneous abortions is still a great problem. Although a great many vitamin and hormone preparations have been reported to be efficacious, there is still a great need for improved results. Recently the newer progesterone preparations have shown promise. Dr. E. C. Reifenstein Jr. has reported favorable results with a long-acting injectable progesterone in patients who have habitual abortion.

There are still many unknown factors preventing conception. These factors defy even an exhaustive survey of the infertile couple. Many of these factors may be psychogenic. Perhaps many are immunological.

Summary

The age of the wife at the time of marriage has been shown to have a direct bearing on the incidence of sterility. Birth control measures, in themselves, have little effect on infertility, except to place the wife into an older age group having a statistically higher incidence of infertility. The diagnostic survey may appear to be tedious and time consuming. However, adequate treatment without an exhaustive diagnostic regimen is impossible. Fortunately, though difficult to explain, many patients will conceive during or immediately after such a survey.

Perhaps, in the future, the physiologist or chemist will discover a pure pituitary hormone for induction of ovulation, the psychiatrist will be more helpful in reducing stress and anxiety, and the immunologist will discover the remaining factors.

HEMORRHAGE AND MASSIVE TRANSFUSION

Alex W. Ulin, M.D., Seymour W. Gollub, M.D., Ph.D., H. Saul Winchell, M.D.
and
Edward W. Ehrlich, M.D., Philadelphia

Studies were made of the blood clotting system of 38 patients who received massive transfusions in connection with cardiac surgery. Of 30 patients who underwent open-heart surgery, 19 received from 3,000 to 11,500 cc. of blood and did not bleed, while 8 received from 4,000 to 21,000 cc. of blood and did bleed. Eight patients who underwent closed-heart surgery, and had hemorrhagic episodes subsequently, received from 3,100 to 15,000 cc. of blood. It appeared that the hemorrhages observed were more probably the occasion rather than the result of the massive transfusions. Eight quantitative laboratory tests were applied to blood samples from these patients, before, during, and after the surgery, but no common cause of bleeding was evident. There was no significant difference between bleeders and nonbleeders with respect to platelet count, fibrinogen concentration, or status of the plasma coagulation system either preoperatively or postoperatively. It would appear that massive transfusion aggravates a tendency for "unexplained bleeding in the surgical patient," but the primary blame for hemorrhage cannot be placed on compatible massive transfusions.

Within the past few years, concomitant with advances in techniques of collection and storage of blood and the daring innovations of modern surgery, there has been described a new syndrome called "hemorrhage due to massive transfusion." This condition is an uncommon complication of surgery, but is particularly associated with large-scale procedures. Its cause is said to be thrombocytopenia by one group,[1] while another group ascribes this syndrome to fibrinolysin[2] and, more recently, multiple clotting defects.[3]

We would like to describe in summary fashion[4] some key findings to date of a study of the blood clotting system of 38 patients who received massive transfusions at Hahnemann Hospital last year, mostly from the department of thoracic surgery, under the direction of Dr. Charles P. Bailey.

Twenty-two patients underwent open-heart surgery and did not bleed (nonbleeders). Eight patients underwent open-heart surgery and did have a hemorrhagic episode (bleeders). Eight patients underwent closed-heart surgery and did have a hemorrhagic episode (bleeders). Excluded from definition of bleeders are those who bled from mechanical causes. No obvious preoperative differences between bleeders and nonbleeders were seen. It is our broad aim to answer three questions about these patients, and these will be considered in order.

Relationship of Bleeding to Transfusion

Is bleeding due to massive transfusion or is massive transfusion given because of hemorrhage?

The volumes of blood given to the patients in 24 hours or less—usually less—were as follows: Nineteen patients underwent open-heart surgery, received an average of 5,400 cc. of blood (extremes, 3,000-11,500 cc.), and did not bleed. Bleeders got a mean total volume of blood that was approximately twice that of nonbleeders. The eight bleeders who were subjected to open-heart surgery received a mean total of 9,500 cc. (extremes, 4,000-21,000), and the eight who underwent closed-heart surgery received 9,000 cc. (extremes, 3,100-15,000 cc.). But, up to the time of bleeding, bleeders in the two groups received about the same total volume as nonbleeders (means, 6,000 and 4,600 cc.; extremes, 4,000-7,750 and 2,000-7,000 cc. respectively).

These data suggest two important concepts: 1. In the patients studied, massive transfusion may have been necessary but was not sufficient in itself to produce hemorrhage. 2. The large volumes of blood given to bleeders were given, in greatest measure if not entirely, because of the hemorrhage, and thus were a result rather than a cause of hemorrhage.

Defect in Plasma or Platelets

Was there a defect in plasma or platelets? To answer this question, we examined the coagulation system. Figure 1 (*left*) gives the platelet values of patients who underwent open-heart surgery. The ordinate is the count of platelets in 1,000 per cubic millimeter. The abscissa shows the times of sampling: initial, preshunt, postshunt, two hours after operation, and 24 hours after operation. The curve at the top shows the results for the total open-heart surgery group. It will be seen that the platelet level fell during the postoperative period and was then maintained. The curve at the bottom shows values of bleeders' platelets and nonbleeders' platelets. It will be noted that there was little difference between them at any given time. This finding is significant, because bleeding was usually manifest during the immediate two-hour postoperative periods.

From the Blood Coagulation Research Laboratory and the Department of Surgery, Hahnemann Medical College and Hospital.

Read before the Section on Pathology and Physiology at the 107th Annual Meeting of the American Medical Association, San Francisco, June 24, 1958.

Thus, with use of proper controls, i. e., patients who received massive transfusion but did not bleed, we see that thrombocytopenia may have been necessary but was not sufficient to produce hemorrhage. We ascribe the thrombocytopenia to dilution of patient blood with platelet-poor transfusion blood in part. Other data support this concept.

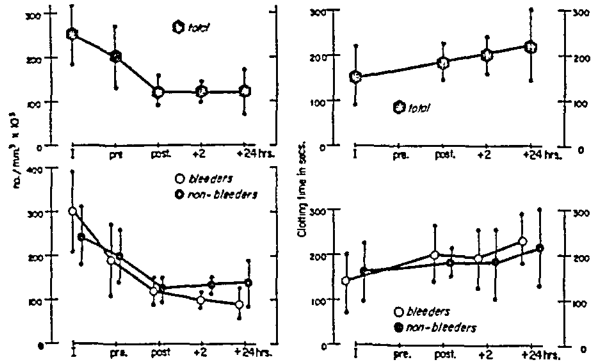

Fig. 1.—*Left,* absolute platelet values and, *right,* absolute recalcified plasma clotting times in patients subjected to open-heart surgery.

The plasma recalcified clotting time of the patients subjected to open-heart surgery (fig. 1, *right*) is a measure of the integrated functioning of the plasma coagulation factors. Examination of the lower two curves shows no difference between bleeders and nonbleeders that is clinically significant.

Figure 2 is concerned with other blood clotting tests. The thromboplastin generation test (*left*) was used to evaluate the early stage. Examination of the lower two curves indicates that there is no significant difference between bleeders and nonbleeders. Similar results were obtained with the prothrombin consumption tests.

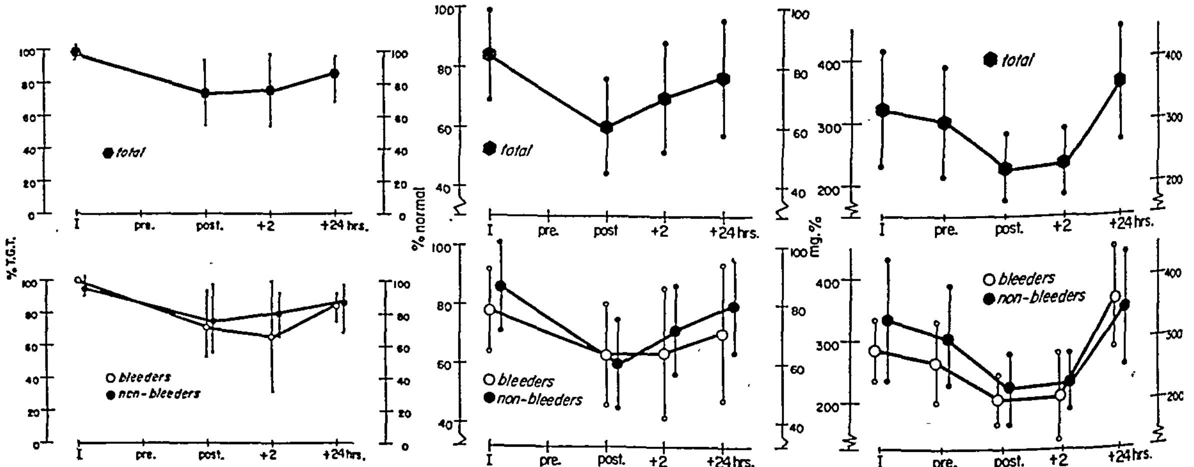

Fig. 2.—Absolute values for, *left,* thromboplastin generation, *center,* one-stage prothrombin level, and, *right,* fibrinogen level in patients subjected to open-heart surgery.

The intermediate stage of blood clotting was evaluated with the prothrombin time determination (fig. 2, *center*). An examination of the bottom two curves shows no significant difference between bleeders and nonbleeders.

The final stage of blood clotting, analyzed on the basis of conversion of fibrinogen to fibrin, is illustrated in figure 2 (*right*). Again, examination of the bottom two curves shows no significant difference between bleeders and nonbleeders. Of interest is the marked 24-hour rise in both groups.

In regard to fibrinolysin in patients who underwent open-heart surgery, only two bleeders had significant fibrinolysin titers. Also, two nonbleeders had significant fibrinolysin titers. Fibrinogen levels correlated well in these four patients. Otherwise, fibrinogenopenia was not in evidence. Fibrinolysin was not impressive. No anticoagulant activity was found in any patients' samples at any time.

Considering next the findings of the blood clotting studies of bleeding patients in the closed-heart surgery group, we may summarize by saying that they were remarkably similar to the data already presented and corresponded test for test with the bleeders in the open-heart surgery group. In addition, there was no correlation between volumes of blood administered and depression of clotting factors or platelet levels. Positive fibrinolysin titer was present in the sample of one patient in the closed-heart surgery group.

Thus, considering the average values of groups of patients, we may conclude that there was (1) no difference between bleeders and nonbleeders' platelet values, (2) no difference between bleeders and nonbleeders' plasma coagulation system, and (3) no fibrinogenopenia, with fibrinolysin not impressive.

Common Cause of Bleeding

Is there a cause of bleeding which is common to the bleeders? To answer this, we will examine the individual cases of bleeders subjected to open-heart surgery and interpret each one as an isolated case of bleeding. We find that the outstanding defects were as follows: thrombocytopenia, 2 patients; acute depression of thromboplastin generation, 1; acute hypoprothrombinemia, 1; significant fibrinolysin titer, 2; findings consistent with a process of intravascular coagulation, 1; and problematical, 1. Therefore, no common cause of bleeding is evident.

Summary and Conclusions

Data on 38 patients receiving massive transfusion, including 16 "bleeders," show that massive transfusion was not sufficient in itself to produce hemorrhage. Massive transfusion may be, and probably in large part was, a result rather than a cause of bleeding. A common cause for bleeding was not evident for all cases. Thrombocytopenia was not sufficient to produce hemorrhage. Fibrinogenopenia and/or fibrinolysin was not impressive. The vasculature is as yet uninvestigated.

Consequently, we cannot place the blame for hemorrhage on compatible blood transfusions. Transfusions may initiate or aggravate the bleeding due to a defective mechanism or a system already primed for hemorrhage. Therefore, every patient to undergo surgery, regardless of magnitude and type of operation, who seems to show a likelihood of requiring transfusions should have a complete investigation of coagulation factors. This would detect a possible defect that could become clinically significant. In this way, specific therapy with the proper blood fraction or factor could be instituted.

ACUTE INTERMITTENT PORPHYRIA WITH RESPIRATORY PARALYSIS

Stanley G. Doll, M.D., Downey, Calif., Albert G. Bower, M.D.
and
John E. Affeldt, M.D., Los Angeles

Porphyria is characterized by remissions and exacerbations; it causes death by producing respiratory failure. Three patients with respiratory involvement during recurring episodes of intermittent porphyria were treated by tracheotomy and mechanical respiratory assistance. The cases serve to emphasize that such patients may recover from their respiratory complication and be ambulant, even after a prolonged illness and in spite of continued excretion of porphobilinogen. Use of the respirator is emphasized, because it will prevent death due to paralytic respiratory failure, thus allowing time for clinical remission and recovery.

Acute intermittent porphyria occasionally may be responsible for respiratory failure and death.[1] Neurological complications of acute porphyria were described as early as 1890,[2] and more cases were soon added.[3] Denny-Brown and Sciarra [1a] stated that the bulbar manifestations in a severe attack of acute porphyria are the usual cause of death. One of their patients was kept in a respirator and died during the second attack two years later. Melkerson and other workers [4] have reported cases of patients recovering from bulbar paralysis. Hoagland [1b] found that once neurological change occurs the mortality is about 75%, death being due to bulbar involvement with respiratory paralysis. He also stated that such patients relapse and few survive more than five years after the initial attack. Markovitz [5] reviewed 64 cases from 1941 to 1953 and added five of his own. His review revealed that when the central nervous system was involved, especially the cranial nerves, the mortality ranged from 60 to 90%. Therefore, cranial nerve involvement indicates a bad prognosis: of 69 patients, 35 had cranial nerve involvement and 22 died. Vocal changes occurred in 26 patients. The patient in one of the five new cases he reported died in respiratory failure. Use of the mechanical respirator was not mentioned.

From the Communicable Disease Service, Los Angeles County Hospital; the Respiratory and Rehabilitation Center for Poliomyelitis, Rancho Los Amigos Hospital, Downey, Calif.; and the Department of Internal Medicine, College of Medical Evangelists, Los Angeles.

Acute intermittent porphyria is characterized by exacerbations and remissions. Consequently, it is conceivable that, if a patient can be tided over the period of respiratory failure by supportive means, such as a mechanical respirator, he might return eventually to a relatively normal existence. We would like to report on three patients who had respiratory failure, who required a respirator, and who later became free from respirator care. Though such patients are subject to subsequent attacks, this report shows they may not produce bulbar or respiratory manifestations.

Report of Cases

Case 1.—A 27-year-old woman was admitted first to an outlying hospital on April 15, 1956, because of red urine. Except for dizzy spells, weakness, and backache occurring intermittently since childbirth in 1954, she had been well. On April 13, 1956, she had a sudden onset of severe back pain associated with generalized weakness and anorexia. Red urine was then seen. Numerous studies were made, but she was discharged seven days later, being told that it was "all in her mind." She was admitted next to a sanitarium and kept overnight, being told that, although she had a nervous condition, she also was physically ill. Then she saw a chiropractor. She became weaker and anorexic, losing 11 lb. (5 kg.) in three weeks. She had difficulty in swallowing liquids. She had abdominal cramps and vague leg and chest pains. She lost the use of her arms and legs. She was referred to the White Memorial Hospital, Los Angeles, on May 2, 1956, with the diagnosis of possible adrenal cortical hypofunction (Addison's disease) or uremia.

The patient's history revealed that she had had constipation most of her life, and this had become more severe since her present illness. She previously had had "dark urine," but the duration or beginning was not recorded. She had grand mal convulsions as a child. One sister also had this, as well as a "nervous breakdown" at the age of 21. Her parents and eight siblings are all living and well. There was no family history of porphyria.

On physical examination on May 3, the patient had an anxious look and was distraught. She spoke in a barely audible whisper. The temperature was 101.8 F (38.7 C) rectally, respiration rate 28 per minute, and pulse rate 134 per minute. Blood pressure was 150/100 mm. Hg. She had many freckles but no unusual pigmentation. Her pupils were widely dilated, and there was a slight downward deviation of the left eye. The gag reflex was normal, but swallowing was impaired. No tenderness, rigidity, enlarged viscera, or mass was noted in the abdomen. There was total flaccid paralysis of all extremities. Sensory function was intact. The deep tendon reflexes were absent except for the ankle reflexes, which were 2+ bilaterally.

Laboratory studies were done on May 4. The hemoglobin level was 13 Gm. per 100 cc. The white blood cell count, hematocrit value, and serum potassium level were normal. Total porphyrin level in the urine was increased, and findings on the test for porphobilinogen were strongly positive. The urine turned dark on exposure to the sun. The fasting blood sugar level was normal. The urine was cloudy and amber-colored, with a specific gravity of 1.016; there were 5 to 10 red blood cells and 8 to 10 pus cells per high-power field. Findings on the Venereal Disease Research Laboratory and Kolmer-Wassermann tests were negative.

Soon after admission, an intern gave 250 mg. of amobarbital (Amytal) sodium intravenously in an attempt to slow the pulse rate; this was without effect. The diagnosis of acute intermittent porphyria was subsequently made, and further use of barbiturates was banned. On May 5, a consulting neurologist confirmed the diagnosis of neuronitis with porphyria. He advised intravenous administration of procaine, 1 Gm. per liter of 5% glucose solution daily, and 10 mg. of prednisolone every four hours by Levin tube; both recommendations were followed. He noted a definite neuropathy of the facial nerve (Bell's palsy) on May 6. At that time, the patient could not wrinkle the forehead, close her eyes, or purse her lips. Tetracycline (Achromycin) was given because of a urinary tract infection in doses of 250 mg. four times daily. By May 7, the patient was unable to swallow and tube feedings were started.

On May 8, the patient was in respiratory distress and she was transferred to the Communicable Disease Unit of the Los Angeles County Hospital for respirator care. The alveolar carbon dioxide tension was 55 mm. Hg (normal 40), giving evidence of hypoventilation.

She was emaciated, disoriented, and acutely ill. She had scanning speech and pooled secretions in her throat. Respiratory excursions were poor. The muscles were described to be of a "doughy" consistency. She had generalized muscle fibrillations with paresis of all four extremities. A chest roentgenogram taken on May 8 showed normal findings.

Total urine porphyrin and urine porphobilinogen levels were highly elevated. An electroencephalogram taken on May 17 showed a normal tracing.

On the day of admission to the Communicable Disease Unit, a high tracheotomy was done and the patient placed in a respirator. Tetracycline therapy was continued and intravenous administration of vitamins was started. Three days later, the patient was rational and had no difficulty in swallowing, but she became irrational periodically. The temperature returned to normal, and less fibrillatory movement was noted in the muscles. Within seven days the patient was allowed short periods out of the respirator. On June 4, her vital capacity was 1,800 cc. (62% of her predicted normal).

On June 7, 1956, the patient was transferred to the Rancho Los Amigos Hospital Respiratory Center. The tracheotomy tube was still in place. She had bilateral upper extremity weakness. The lower extremities showed good function throughout, with the exception of poor quadriceps. The breathing pattern was predominately intercostal, and she tended to use neck accessories during quiet breathing. Obvious disturbance of laryngeal function was demonstrated by speech and cough. By June 12, she tolerated being out of the respirator for one and one-half hours twice a day; her time out was increased about one-half hour per day, with complete freedom by July 12, 1956. Findings on tests for urine porphyrins (including porphobilinogen) were still strongly positive. Findings on the tests for urine porphobilinogen became negative first on July 16, about three months after the acute episode began. At the height of her illness, she weighed about 60 lb. (27.2 kg.). By Aug. 16, the patient was able to get in and out of bed alone and go to the bathroom with minimal help.

She had been started on a program of muscle reeducation and strengthening to all four extremities after admission to Rancho Los Amigos Hospital. Diaphragm reeducation and coughing exercises were given. The patient was discharged Aug. 17, 1956, at her request, to return to the eastern part of the United States.

No further contact was had with her until Jan. 6, 1957, when she was readmitted to the Los Angeles County Hospital with abdominal pain of one week's duration. Prior to this readmission, she had been hospitalized elsewhere and given medicaments, including barbiturates, by hypodermic every four hours for pain. No complaints referable to the muscles were made on admission, and she weighed 80 lb. (36.3 kg.). On physical examination her blood pressure was 130/90 mm. Hg, pulse rate 120 per minute, and respiration rate 20 per minute. She was alert and cooperative. Her deep tendon reflexes were 3+. Sensory functions were intact. The 24-hour urine examination showed positive findings for porphyrins and porphobilinogen. The hemoglobin level and red and white blood cell counts were normal. The patient was given 50 mg. of chlorpromazine (Thorazine) hydrochloride intramuscularly and thereafter 50 mg. every four hours by mouth. On Jan. 10, the knee and ankle reflexes were absent and the patient was emotionally labile, but she had no trouble breathing. Subjectively and objectively she improved rapidly, and she was discharged on Jan. 17, 1957. No additional follow-up data are available.

Case 2.—A 61-year-old man was referred to the Communicable Disease Unit of the Los Angeles County Hospital on June 19, 1956, from another hospital, with the diagnosis of acute porphyria with an ascending type of lower motor neuron paralysis and severe respiratory distress. He had developed abdominal pain on Feb. 11, 1956, which was thought to be a recurrence of ureteral colic, which he had had seven years previously.

The onset of paralytic symptoms began about June 9. He gradually developed paralysis of the lower and then the upper extremities. His voice dropped to a hoarse whisper. On the day of admission, he was dyspneic.

His history was not detailed, except that he had had an appendectomy. System review was negative. His family history revealed that a niece had died with porphyria in 1955 at the age of 27 years.

The patient was described as an acutely dyspneic, perspiring man lying in a "frog-like" position with flaccid extremities. He talked in a whisper, appeared quite anxious, and stated that he was tired. Blood pressure was 140/100 mm. Hg, pulse rate 90 per minute, and respirations 32 per minute and shallow. Temperature was 99 F (37.2 C) rectally. A healing vesicular exanthem was noted over the anterior chest and inner angle of the eyebrows. The lower part of the abdomen was flaccid, and bilateral upper and lower extremity paralysis with muscle atrophy was present. Sensory modalities were intact. Reflexes were absent in the lower extremities, with the exception of a normal plantar response. Weak biceps reflexes were present. The gag reflex was intact. Swallowing was normal, and there was no hypopharyngeal pooling of secretions.

Laboratory studies showed the hemoglobin level and white blood cell count to be normal. The urine was not dark; it contained a trace of albumin and many red blood cells per high-power field. A chest roentgenogram showed both sides of the diaphragm to be elevated with a plate-like atelectasis present at the right base. Results of the test for urine porphobilinogen and uroporphyrin were strongly positive, and the urinary coproporphyrins level was slightly elevated. An electromyogram of muscle groups of the upper extremities, chest, abdomen, thighs, and legs was done July 19, 1956. This showed a lower motor neuron disease of diffuse nature.

At the time of admission to the Communicable Disease Unit, his vital capacity was 800 cc. (23% of predicted normal) and the tidal volume 100 to 150 cc. The patient was placed in a Drinker respirator. He was slightly disoriented. A retention catheter was used until July 3. Procaine penicillin G in aqueous suspension (Crysticillin), dimenhydrinate (Dramamine), and aspirin were given. The patient had been placed on sulfisoxazole (Gantrisin) therapy for mild urinary tract infection.

On July 5, when transferred to the Rancho Los Amigos Hospital Respiratory Center, the patient had no difficulty in chewing, swallowing, or urinating. Speech was hoarse and ability to cough very poor. The breathing pattern was that of the chest and accessory muscles without demonstrable diaphragmatic function. There was no facial or neck muscular weakness, but the abdominal and extremity muscles were all weak.

By July 16, some soft-palate weakness, with the uvula deviating to the left, was noted. A month after admission, the patient became paranoid and disorientated. He developed severe atelectasis, and, on Nov. 2, an emergency tracheotomy was performed. There was slow but gradual recovery, punctuated by recurrent bouts of atelectasis, complaining behavior, and abdominal pains with occasional vomiting. Urine porphobilinogen remained present throughout his hospital stay, with the last urine porphobilinogen level recorded on May 23, 1957. In spite of the continuous excretion of porphobilinogen, there was gradual improvement. By Feb. 28, 1957, he had begun to stand and walk without the aid of respirator equipment; the vital capacity was 2,025 cc., diaphragmatic function was normal, and function of the upper extremities was rated as good. By April 3, no respirator assistance was required. A course of dimercaprol (BAL) therapy was started on May 20 and continued for five days without improvement in muscle power. On June 15, 1957, he was discharged, and 24 days later he stopped using a wheel chair. He has not required respirator assistance since (follow-up until March 28, 1958).

Case 3.—A 6-year-old girl was admitted to the Communicable Disease Unit on Feb. 24, 1956. She had been well until 17 days before admission, when she complained of abdominal pain and malaise. She vomited once but had no fever. During the day of onset, the pain was intermittent; it became progressively worse, and she was operated on for appendicitis in an osteopathic hospital. The discharge diagnoses there included "acute obstructive appendicitis," "postappendectomy paralytic ileus," "malnutrition," and "subacute glomerular nephritis." She had dark urine. On about Feb. 20, 1956, the patient developed weakness of the extremities and respiratory distress with inability to cough. She was transferred to the Communicable Disease Unit, where respiratory equipment was available.

Further history revealed that the maternal great grandfather and the patient's mother both had had porphyria. The mother's first attack was 10 years previous, with dark red urine present and pain in the abdomen and legs.

Physical examination showed the temperature to be 100.6 F (38 C) and the pulse rate 160 per minute. She was anxious; breathing was labored and paradoxical, with the intercostals predominately used. The gag reflex was hypoactive and there was some pooling of secretions in the throat, but she still could swallow. The ability to cough was very poor. There was marked generalized weakness. Sensory functions were intact, although both the superficial and deep tendon reflexes were absent. Plantar response was normal.

Laboratory studies revealed a hemoglobin level of 11.4 Gm. per 100 cc., red and white blood cell counts normal, blood urea nitrogen level 23.5 mg. per 100 ml., and serum potassium level 3.1 mEq. per liter. The 24-hour urine creatinin level was 2,058 mg. Results of tests for urine porphyrins (total and porphobilinogen) remained positive, the last time tested being June 8, 1956. Examination of the spinal fluid was normal. A chest roentgenogram showed suggestion of right apical atelectasis. Microscopic slides of the appendix were obtained and studied, and no pathosis was noted.

The patient was subjected to tracheotomy and placed in a respirator on the day of admission. Three days later, chest fluoroscopy revealed that there was a paradoxical motion of the diaphragm. She was started on tetracycline therapy for respiratory infection. She was kept on therapy with 250 mg. of thiamine given twice daily for nearly two months. By June 1, she was out of the respirator 12 hours on her own and by June 4 was in her own bed during the entire 24 hours.

She was transferred to the Rancho Los Amigos Hospital Respiratory Center on June 7, 1956. Examination revealed that she had a strong diaphragm. Her vital capacity was 50% of normal. By July 17, she was so improved she used a free gait for two hours per day instead of the walker. One month later (Aug. 13, 1956) the patient was discharged with bilateral short leg braces.

The patient was again admitted to the Communicable Disease Unit on Oct. 6, 1956, for severe abdominal pain. Intermittently, she had had dark urine since June 7. Moderate bilateral atrophy of both legs and thighs was present. The urine was dark red-brown. Aspirin, chlorpromazine, and codeine were given. She had a fluctuating temperature to 104 F (40 C), but improvement was rapid and she was discharged Oct. 16, 1956. Leg braces were removed on Nov. 8, but she fell occasionally. Both her and her mother's urines were positive for porphobilinogen.

The patient was readmitted to the Communicable Disease Unit on Feb. 20, 1957, for stomach pains of five days' duration, constipation for three days, and leg pains for one day. At this time, her mother stated that the child's urine had been dark red-pink since her first attack in February, 1956, even when she was fairly well, but had become redder during the present attack. She was given chlorpromazine, 10 mg. four times per day. She was discharged improved three days later.

She was readmitted to the same unit on June 17, 1957, and discharged improved two days later, still on chlorpromazine therapy. The intermittent pains in the legs, abdomen, and chest were insufficient to require prolonged hospitalization. The patient has not been seen since.

Comment

Three cases have been described with respiratory involvement during recurring episodes of intermittent porphyria. These patients' treatment included tracheotomy and mechanical respiratory assistance.

All three patients developed respiratory failure due to paralysis of the respiratory muscles. They also accumulated secretions in the airway due to bulbar paralysis or inadequate cough. Either respiratory paralysis or obstructed airway, or the combination, as observed in these patients, will produce death in a very short time. Death due to respiratory failure can be prevented by mechanical medical assistance.[6] Tracheotomy will bypass the obstructive material in the hypopharynx and permit adequate and frequent suctioning of the lower airway, and a mechanical respirator will provide adequate ventilation for as long as necessary.

Porphyria is characterized by remissions and exacerbations; it causes death by producing respiratory failure. If respiratory function is maintained mechanically, time may bring about a remission. Although repeated exacerbations of the disease may be fatal, these cases indicate what sort of recovery is to be expected during the year after the acute onset. These serve to emphasize that such patients may recover from their respiratory complication and be ambulant, even after a prolonged illness and in spite of continued excretion of porphobilinogen.

Chlorpromazine was not put specifically to a clinical test for evaluation of the results. Universal recognition and medical diagnosis of this disease is still lacking, and needless surgery and drug administration is still noted. These have aggravated the underlying condition in most new cases that have been described. Inasmuch as the condition is inherited, a good history may suggest the diagnosis even before the urine porphobilinogen test is done. Until the disease is better understood and control measures are available, supportive treatment is indicated in the attempt to attain a prolonged remission. At present, there is more information on what not to give the patient in the way of treatment than there is on what to give. Chlorpromazine currently is being tried, but, though frequently helpful, it is not the therapeutic answer. The respirator is a useful tool to tide over patients with respiratory paralysis and, if used, can forestall, at least temporarily, what otherwise is certain death.

Summary

Three case reports have been given of acute intermittent porphyria in which respiratory failure developed. Treatment included use of the respirator until respiratory muscle function returned during the period of remission. Use of the respirator is emphasized, because it will prevent death due to paralytic respiratory failure, thus allowing time for clinical remission and recovery.

One patient was noted to improve clinically in spite of continuing positive urinary porphobilinogen findings; the other two improved as the urinary prophobilinogen excretion decreased.

BALANCED ANALGESIA FOR THE POOR-RISK PATIENT UNDERGOING THORACIC SURGERY

Crisostomo C. Santos, M.D.
and
Robert B. Sweet, M.D., Ann Arbor, Mich.

The term "balanced analgesia" implies the production of anesthesia with use of several agents, often administered by different routes, which are detoxified and excreted in several different ways. In brief, it is simply balanced anesthesia minus true hypnosis. In dealing with a poor-risk patient the friendly and informal approach to the patient is the most humane. Most of these patients are fully cognizant of their precarious condition before they elect to undergo an operative procedure. It is a well-established clinical thesis that shock or functional impairment of the circulation will often be induced in borderline patients by general anesthesia, particularly during prolonged procedures. There are four merits of a balanced analgesic technique: 1. The anesthetic agent and supplemental drugs used are almost universally acceptable to all patients. 2. There is minimal disturbance of physiologic mechanisms. 3. A relatively wider margin of safety for the patient and optimal working conditions for the surgeons are provided. 4. There is a relatively shorter and uneventful postoperative course.

The rapid growth and progress of surgery on the poor-risk patients for thoracic surgical procedures have served to intensify the problems of the anesthetist. Today we are not simply concerned with just an alive patient after a hazardous operation; we attempt, with a high degree of assurance, not to upset any further the physiological balance present prior to operation. We also consider of equal importance the rapid and uneventful postoperative recovery of the patient, with a short, pleasant, and safe convalescence. With these as primary motives, the use of the analgesic technique was revived and further improved, and it consequently has gained recognition and popularity among several of the teaching centers in anesthesiology.

The value of analgesia was first suggested in 1847 when Snow[1] described it with use of diethyl ether. Snow observed that an analgesic state existed after emergence from deeper degrees of etherization. In 1921, Gwathmey[2] reported on ether analgesia by the oral route for operations of short duration and for dressing wounds during World War I. He claimed that patients under the effects of ether analgesia answered questions, suffered no pain, and had no memory for the entire event. It was not until January, 1955, that this idea was revived and reevaluated by Artusio.[3] He gave a detailed description of the first stage of diethyl ether anesthesia in man and reported his technique for major surgical procedures, particularly heart surgery. Two years later, Schotz and co-workers[4] reported on succinylcholine and inhalation analgesia for major cardiac and pulmonary surgery.

We are reporting another technique along this line, which was developed at the University of Michigan Hospital and used on 100 patients undergoing thoracic surgery and thought to be poor risks. The term "balanced analgesia" was coined and may be said to have evolved from its immediate predecessor, "modern balanced anesthesia."[5] The latter implies the production of anesthesia with use of several agents, often administered by different routes, which are detoxified and excreted in several different ways. Balanced analgesia, in brief, is simply balanced anesthesia minus true hypnosis.

Technique

All patients are seen the evening before surgery. A complete evaluation of the patient's chart is made before the actual interview. This includes a review of his complete history, physical examination, laboratory examination, past and present drug therapy, and previous operative and anesthetic procedures. The conversation with the patient is in a most friendly and informal manner. At this time he is reassured, and rather detailed information of the preanesthetic and anesthetic procedure, including postoperative care, is outlined. However, every precaution is taken not to tell the patient that he will be conscious and questioned during the surgical procedure.

Preoperative medication consists of an adequate oral dose of pentobarbital sodium given the evening before surgery to assure a restful night's sleep for the patient; another dose of the same drug is given two hours before induction of anesthesia. A moderate dose of morphine sulfate, 6-10 mg., and scopolamine, not to exceed 0.3 mg., is administered by the subcutaneous route one hour before induction of anesthesia.

When the patient arrives at the anesthesia induction room, provision for the convenient intravenous administration of drugs is provided by means of a three-way stopcock attached to an 18-gauge needle in an arm vein, preferably in the down side when the patient is in the lateral operative position. Read before the Section on Anesthesiology at the 107th Annual Meeting of the American Medical Association, San Francisco, June 26, 1958.

ical anesthesia of the larynx and tracheobronchial tree is obtained either transtracheally along with simultaneous administration of 100% oxygen or transorally by means of a spray immediately before endotracheal intubation. We believe a 10% solution of cocaine to be the drug of choice. Depending on the level of the initial blood pressure, meperidine hydrochloride in a 1% solution is given intravenously in 10-mg. dosage increments until the patient develops signs of partial analgesia to moderately painful cutaneous stimulation. An interval of ap-oximately two to three minutes is allowed be-veen the dosage increments to allow sufficient ne for the effect of the meperidine to be ob-rved, since most of these poor-risk patients have prolonged circulation time. Additional doses of ieperidine are not given if any significant degree f hypotension develops. If hypotension should occur, ventilation is provided with 100% oxygen and the patient is placed in a modified Trendelenburg's position until the blood pressure returns to the initial level. As soon as the patient's blood pressure becomes stable, with or without partial analgesia, induction is carried out with intravenously given thiamylal sodium in a 2% solution administered intermittently in 20-to-40-mg. doses to the point of mild hypnosis. By mild hypnosis we mean the state in which the patient will barely respond to simple questions. A 40-mg. dose of succinylcholine in a 2% solution is given intravenously to accomplish a fast and atraumatic oral intubation with an appropriate size of Portex endotracheal tube. Ventilation is again provided with 100% oxygen before the endotracheal tube is connected to a semiclosed circle absorption system. From this point on, the respiration is continuously controlled until the chest is completely closed.

We prefer to use either a Forreger or a Heidbrink machine, which has a wide and easily readable form of calibration for both nitrous oxide and oxygen in liters per minute. We then start the administration of a gas mixture with 1½ liters flow of oxygen and 3½ liters flow of nitrous oxide and allow the patient to breathe this mixture for about 15-20 minutes. This time period will permit denitrogenation and allow a sufficient but safe concentration of nitrous oxide to be attained in the patient's system. A continuous slow drip of 0.2% solution of succinylcholine, set at 8 to 10 drops per minute, is begun. This is used to prevent the initiation of possible dangerous reflex cardiac arrhythmias from the operative manipulations inside the chest, but in such minimal doses it is inadequate to produce total neuromuscular block.

The patient is then placed in position for the proposed operative procedure. During the usual sterile preparation and draping, the patient is tested as to the degree of analgesia attained. The concentration of nitrous oxide is then varied between 0 and 67% for maintenance of complete analgesia without true hypnosis. Several doses of meperidine, 1% solution, are administered intermittently to fortify the state of analgesia provided by nitrous oxide. The nitrous oxide and meperidine are continuously titrated to maintain the desired type of analgesia. Prior to surgery an intravenous 16-gauge needle is placed for blood replacement.

When the pleura is incised and after the rib retractor is in place, 10 cc. of a 1% solution of lidocaine is infiltrated into the hilum of the lung on the operative side to eliminate bucking on the endotracheal tube consequent to surgical manipulation and compression of the lung. Electrocardiographic recordings are made throughout the surgical procedure with a Cambridge operating room cardioscope or a direct writer. Blood pressure and pulse rate are also monitored carefully. Adequate measurement of blood loss and replacement is assigned to the operating room circulating nurse under the supervision of the anesthesiologist.

Through the surgical procedure, the patient is questioned intermittently as to his perception of pain and comfort. The patient's ability to think is tested by means of simple commands and questions, and his ability to hear is determined by spoken voice. When there is only partial analgesia, the patient clinches his fingers tightly or grimaces, moves on painful stimulation, and indicates on questioning that pain is present. The control of these undesirable signs and symptoms of inadequate analgesia through the use of relaxants is illogical. Instead, we believe it is more rational to increase the safe concentration of nitrous oxide and/or administer meperidine in order to obtain total analgesia. When there is hypotension concomitant with partial analgesia, we prefer to increase the concentration of nitrous oxide; when partial analgesia is not accompanied by hypotension, it is preferable to give additional increments of meperidine, since it has a less hypnotic effect than nitrous oxide.

Postoperatively, the patients were totally amnesic for the events during the entire operative period, including the state of partial analgesia. In general, the postoperative course was short, uneventful, and relatively free of significant complications. The thoracotomy drainage was usually removed on the second postoperative day and the patient was ambulant on the same day.

Results

The types of operative procedures carried out in this series, with use of this particular analgesic technique, were as follows: mitral valvuloplasty or valvulotomy (77), Beck 1 operation (1), repair of mitral insufficiency (2), pericardiectomy (2), Hufnagel's operation for aortic insufficiency (1), aortic commissurotomy (heart-lung bypass) (2), repair of infundibular pulmonary stenosis (heart-lung bypass) (1), Pott's anastomosis (1), repair of coarctation of aorta (2), ligation of patent ductus arteriosus (1), transthoracic exophagectomy and esophagogastrostomy (3), repair of coarctation of aorta and ligation of patent ductus arteriosus (1), revision of esophagojejunostomy (1), right middle lobectomy

(1), excision of multiple lymphatic mediastinal cysts (1), exploratory thoracotomy and pleural biopsy (1), and second stage thoracoplasty (2).

There were 62 women and 38 men; the ages ranged from 4 to 84 years, with an average of 35.38 years. Weights ranged from 38 to 197 lb. (17.2 to 89.4 kg.), with an average of 121.66 lb. (55 kg.). The physical status of these patients (according to the American Society of Anesthesiologists' classification) was between classes 3 and 4.

In order to present a better evaluation of the statistical analysis of our results, we have divided the cases into two groups: (1) operations done on patients for mitral stenosis and (2) operations done on patients for other than mitral stenosis. The different factors taken into consideration are as follows: (1) adequacy of preoperative sedation, (2) effect of preoperative medication on blood pressure and pulse rate, (3) amount of thiamylal (2%) used, *(4) amount of meperidine (1%) administered,* (5) amount of succinylcholine (0.2%) given, and (6) duration of anesthesia.

Only 6% of the patients in both groups (5 of 77 patients in the mitral group and 1 of 22 in the nonmitral) had inadequate sedation from the preoperative medication. After the administration of the preoperative medication, the average decrease in systolic blood pressure was 10.5 mm. Hg in both groups (in 56 and 17 patients, respectively, with average increases of 8.09 in 16 patients and 13.3 mm. Hg in 3, and no change in 5 and 3 patients). The average increase in pulse rate was 8.08 per minute in the mitral group and 7.2 per minute in the nonmitral group (in 35 and 14 patients, respectively, with average decreases of 12.8 in 36 patients and 9.02 in 9, and no change in 6 and 0). The average total amount of thiamylal (2%) given per patient was 126.6 mg. (range, 40-300 mg.) in the mitral group and 126.8 mg. (range, 40-280 mg.) in patients without mitral stenosis. In regard to succinylcholine (0.2%), the average amount administered to the two groups was 334.3 mg. (range, 80-900 mg.) and 473.2 mg. (range, 80-1,000 mg.) respectively. The average anesthesia time for the mitral group was 158.44 minutes (range, 100-345) and 293.26 minutes (range, 155-470) for the nonmitral group. The average weight of the mitral patients was 120.98 lb. (54.9 kg.) and 123.91 lb. (56.3 kg.) for the patients without mitral disease. The average amount of meperidine administered was 0.51 mg. per kilogram of body weight per hour, and the average amount of succinylcholine given was 1.8 mg. per kilogram of body weight per hour in the mitral group of patients; in the nonmitral group, the average amount of meperidine administered was 0.61 mg. and of succinylcholine, 1.7 mg.

Morbidity.—As expected, our patients did relatively well with this particular type of analgesic technique. Most of them maintained their vital signs within the normal limits. Patients with short periods of marked sinus bradycardia were treated adequately with atropine, 0.3 mg. Also some patients had short periods of moderate hypertension and tachycardia from partial analgesia. They responded satisfactorily to additional increments of meperidine and/or increased safe concentrations of nitrous oxide. Patients with severe episodes of hemorrhage, enough to produce moderate to severe hypotension, responded adequately to blood replacement.

In one patient, a saddle embolus and a cerebral embolization occurred during an intra-auricular manipulation of the mitral valve. This patient failed to regain consciousness immediately at the termination of surgery, and bilateral stellate ganglion blocks were carried out on two occasions postoperatively. At the time of discharge from the hospital, this patient was ambulant but still exhibited signs of residual moderate left-sided hemiple Another patient developed a saddle embolus du to the intracardiac exploration and manipulation. T *embolus was removed surgically immediately after* the mitral procedure, and the patient proceeded to do well postoperatively.

One patient developed a short episode of marked hypertension and paroxysmal auricular tachycardia during the induction of analgesia. This patient had been extremely apprehensive prior to surgery, and, on his arrival in the induction room, it was noted that the preoperative medication effect was inadequate. Consequently, there was need for a dose of thiamylal, meperidine, and nitrous oxide greater than usual to produce and maintain the desired state of analgesia.

Mortality.—The over-all mortality in the series was as follows: Of the five patients in the mitral group who died, three died during the operation from severe, uncontrollable hemorrhage due to the markedly calcific and fragile atrial tissues and one died from ventricular fibrillation during multipl prolonged manipulations of the mitral valve. Autopsy findings in this patient revealed marke coronary arteriosclerosis, recent coronary thrombosis, and myocardial infarction. The last patient di suddenly 18 hours after operation from myocardi failure; an antemortem occluding thrombus, exten ing from the left ventricle into the aorta, was foun at the postmortem examination.

An autopsy on the patient in whom mitral commissurotomy and reconstruction of an anomalous pulmonary venous drainage was performed disclosed chronic rheumatic mitral and aortic valvulitis with severe mitral and moderately severe aortic stenosis. Also, a nonfunctioning left superior pulmonary vein which was previously resected from the left subclavian vein and anastomosed into the left atrium was revealed. This patient finally died during the early postoperative period from severe uncontrollable pulmonary edema, primarily in the left lung.

The other two deaths occurred in patients who had had aortic commissurotomy. Ventricular fibrillation developed during the heart-lung bypass. Autopsy findings in both revealed severe calcific aortic stenosis with marked coronary and myocardial degenerative changes.

The six patients who died during operation were doing well with our particular analgesic technique until the occurrence of the tragic precipitating episodes. All patients who survived the surgery and anesthesia, except the one who developed saddle embolus and cerebral embolism, and including the two who died in the early postoperative period, were completely awake and coherent immediately at the conclusion of surgery. All answered questions coherently and cooperated enough to cough when asked to do so and for hyperventilation to be achieved.

Comment

In the management of any anesthetic procedure, the preparation of the patient must be the first consideration. In our experience, we have found the friendly and informal approach to the patient be the most humane, especially when one is aling with a poor-risk patient. Most of these patients were fully cognizant of their precarious condition before they elected to undergo an operative procedure. We found them, as a group, to be extremely anxious and apprehensive during the first visit. By approaching them with confidence and sympathy and, in addition, providing them with detailed information of the anesthetic care, we relieved most of these patients of their anxiety and fear. Several of them commented that the preoperative visit alone, even before premedication was administered, completely changed their apprehensive attitude toward the approaching operation. On arrival in the operating suite, most of them were sufficiently drowsy to be emotionally calm and yet coherent enough to respond to questioning.

We also noted, much to our surprise, that many of the patients in this series who had previous experience with diethyl ether anesthesia were more concerned with the anesthetic agent to be administered than with the operation itself. The request by the patient to "use any anesthetic agent ther than ether" was frequently heard. This is nother reason why we thought of introducing nother technique which was similarly safe but greeable to most patients in general.

Pentobarbital sodium is used as part of the preoperative medication for its known sedative and somnifacient effects. Ordinary hypnotic doses have no significant untoward effects on the vital functions of the body. Morphine is used for the additive sedation it contributes to pentobarbital, for the euphoria it produces secondary to the relief of worry and anxiety, and for its depressant action on the metabolic rate.

Although we are aware of its depressant action on respiration, we believe that its concomitant depressant effect on the rate of metabolism lessens to some degree its full depressant action on respiration when used in moderate doses. Again, when morphine is used in the dosage range we prescribe for our patients, it has little effect on blood pressure and heart rate or rhythm. The average fall in blood pressure in this series after this type of premedication was 10.5 mm. Hg—which we do not consider as very significant. We ascribed this change in blood pressure as secondary to the sedation and lessened physical activity of the patient.

Some anesthetists believe the additive effects of pentobarbital and morphine on the hemodynamics, even in the doses we used and especially to patients with mitral stenosis, may produce adverse results. However, applying the student's T-test and taking the usual 95% confidence level, we were allowed ranges of systolic blood pressure before administration of premedication of 105.999 to 123.845 mm. Hg for the mitral group and 110.449 to 134.595 mm. Hg for the nonmitral group. Therefore, the mean systolic blood pressures of 106.5 mm. Hg and 122.522 mm. Hg in both groups, respectively, which we obtained after the administration of the preoperative medication are within the allowable ranges, and hence the decreases in the systolic blood pressures are not significant.

Scopolamine is selected in preference to atropine because of its sedative, amnesic, and greater drying effects; it has also less cardiac vagolytic action than atropine. Adequate dryness was present in all patients on arrival to the operating suite, and this was reasonably maintained during the rest of the operative procedure. The average increases in pulse rate from the readings taken in the ward previous to the administration of the belladonna drug were 8.08 per minute in the mitral group and 7.2 per minute in the nonmitral group. These increases are not considered as significant to precipitate undesirable ventricular tachycardia.

Again, according to a few anesthetists, any effective drying dose of a belladonna drug may produce untoward response to cardiac rate and rhythm in the form of ventricular tachycardia which may lead to fatal ventricular fibrillation in patients with mitral stenosis. However, applying again the student's T-test and considering the usual 95% confidence level, we were allowed ranges of pulse rate before administration of scopolamine of 70.790 to 89.834 per minute for the mitral group of patients and 73.515 to 89.615 per minute for the nonmitral group. Therefore, the mean pulse rates of 83.1 and 89 per minute in both groups, respectively, which we obtained after the scopolamine was given are within the allowable ranges, and, hence, the increases in pulse rates are not significant. Not only were these decreases in systolic blood pressure and the increases in pulse rate statistically insignificant but also there were a fair number of cases in which increases in systolic blood pressure and decreases in pulse rate were obtained instead.

Cocaine (10%) is our drug of choice for topical anesthesia of the tracheobronchial tree because of its high potency and longer duration of action. On the other hand, in a relatively greater vascular area, such as the hilum of the lung, we prefer lidocaine (1%) for infiltration because of its greater penetrability and lower potency in case of inadvertent intravascular injection.

Nitrous oxide in safe concentration may be considered as the safest and the most innocuous anesthetic gas in clinical use at the present time. It does not possess any untoward effects to tissues and vital function when used in the absence of anoxia. It is nonirritating, nonexplosive, and, in subanesthetic concentrations, definitely analgesic. The optimal concentration of the gas for analgesia without loss of consciousness is 35 to 40 vol. %.[6] However, because of its relatively low anesthetic potency and when used for major surgical procedures, it usually necessitates supplementation by another analgesic agent. In this case, we prefer to use meperidine in intermittent small doses administered intravenously. Like morphine, meperidine produces euphoria secondary to its analgesic action. Although it also exhibits sedation, like morphine, the ratio of its analgesic to hypnotic potency is greater than that of morphine in equivalent doses. Because of its depressant effect on respiration, it requires manual control of the patient's ventilation. With our method of administration of meperidine in these patients, we have noted no significant untoward effects on the cardiovascular system. Mild atropine-like action on the secretory glands of the tracheobronchial tree, on the heart, and on the bronchial musculature are other minor advantages of meperidine which may be worthy of mention.

There need not be any particular preference for the use of thiamylal (2%); another thiobarbiturate derivative, such as thiopental (Pentothal) sodium, may be administered just as well for temporary hypnotic induction to afford additional sedation during the actual visualization of the glottis and the insertion of the endotracheal tube. Because of the ultrashort effect and the relatively small amount of thiamylal used, recovery from the temporary hypnosis is rapid and in a few minutes the patient is able to communicate with the anesthetists. It is interesting to note that the average amounts of 2% solution of thiamylal used for induction in this series were almost identical in both groups. This may be explained on the basis that the average weight of patients in the two groups did not vary appreciably.

Particular preference is given to succinylcholine, a depolarizing relaxant drug, because of its short duration of action and its easy controllability of administration. The 2% concentration of 40 mg. is used for the endotracheal intubation in this series, although the 0.2% concentration, which is administered by the controlled drip during the surgical procedure, might have just as well served the purpose. As was mentioned earlier, in our technique we maintain the succinylcholine drip at the rate of 8 to 10 drops per minute to prevent the initiation of possible undesirable reflex cardiac arrhythmias from operative manipulations inside the chest.[7]

This concept was upheld in this series by the rate occurrence of dangerous cardiac arrhythmias, except in the one patient who developed a sudden ventricular fibrillation during relatively prolonged and multiple manipulations of the mitral valve. This particular patient had chronic hypertension to start with, and autopsy findings revealed coronary and myocardial pathology.

Inasmuch as we did not obtain continuous electroencephalographic tracings in all patients during the operation, to determine and maintain a steady state of adequate analgesia we depended on the patient's responses to painful stimulation either by spontaneous responsive means or by interrogations. On rare occasions, some patients suddenly moved sufficiently on the operating table to disturb the operating conditions, either from inadequate analgesia or from mere restlessness. In this situation, the rate of the succinylcholine drip was increased temporarily until enough time was allowed for the additional dose of meperidine and/or increased safe concentration of nitrous oxide to put the pat back into an adequate analgesic state. However, to maintain apparent analgesia with a potent relaxant, such as succinylcholine, is certainly unfair to the relaxed, helpless patient. We do not believe that a safe concentration of nitrous oxide alone is potent enough to offer the patient sufficient analgesia in major surgical procedures.

On a few occasions, we tried to maintain and control analgesia in some patients with just the maximum safe concentration of nitrous oxide and continuous succinylcholine drip. These patients showed freedom of response from painful stimuli as long as the dose of succinylcholine drip was sufficient to keep them on the operating table, but, as soon as the rate of the succinylcholine drip was decreased to the point where these patients could manifest the inadequacy of nitrous oxide alone in providing sufficient degree of analgesia, control from their dissenting movements would be difficult. The slight to moderate differences in the average total amounts of meperidine and succinylcholine given between the two groups may be a function of duration of anesthesia rather than the patient's physical status.

We prefer the manual controlled type of respiration for our patients because we feel that we can provide more adequate ventilation. Subjectively, by the feel of the bag, we can ascertain to some degree whether the patient is about to take over his own respiration. Objectively, we can vary the intrapulmonary pressure from the degree of expansion of the lung. Furthermore, our surgeons prefer this type of ventilation since they have been used to working with satisfaction under these conditions. In case there is any sign of spontaneous respiration by the patient, we prefer to control the ventilation by physiological means instead of resorting to administration of drugs. The routine hilar infiltration of a local anesthetic immediately on entrance of the chest cavity proves very satisfying to us in the prevention and management of "bucking" during manipulation of the lung. This particular type of infiltration may be repeated once or twice during the whole operative procedure without detriment to the patient.

It has been recognized for a number of years that the experimental animal, when awake, will tolerate about twice the amount of hemorrhage that it will when anesthetized.[8] This was proved to be true in a fair number of our patients, who, because of the marked fragility of their calcified atrial tissue, had episodes of severe blood loss and were still able to regain their relatively normal homeostatic state after adequate blood replacement.

It is also a well-established clinical thesis that shock or functional impairment of the circulation will often be induced in borderline patients by general anesthesia, particularly during prolonged procedures. These observations tend to denote that general anesthesia exerts an untoward influence on the peripheral vascular bed, on the heart, and on the circulating blood volume, all of which may be implicated in the pathogenesis of shock. Moreover, these effects become more profound and deleterious as the depth of narcosis increases.[9] There are still a few anesthetists who believe that surgical trauma, if severe and prolonged enough, will produce the syndrome of shock unless adequate interruption of the noxious stimuli elicited is instituted by administration of regional anesthetics or by induction of deep general anesthesia.[10] However, there is little evidence to support such a concept, and clinical impressions indicate that noxious surgical stimuli in light planes of anesthesia, more so in the analgesic stage, do not necessarily contribute to the syndrome of shock.

In the eight deaths in this series, we did not find any direct cause and effect relationship between mortality and analgesia. The analgesic state permits activity of reflexes which are advantageous to the patient and which help him maintain his physiological equilibrium. The patient's responses to stress of several kinds, such as anoxia, hypercapnia, trauma, and blood loss, would be optimal. Such protective reflex mechanisms are depressed in direct proportion to the depth of anesthesia. The most probable explanation of the protection might be due to the state of delicate balance of the autonomic nervous system during the analgesic state and that a balanced autonomic nervous system is related to cortical control. With the establishment of surgical anesthesia and its concomitant cerebral depression, one part of the autonomic nervous system becomes preponderant over the other and deleterious reflex activity results from this imbalance.[3] From such consideration has emerged the concept that the anesthetist will serve the patient best in his efforts to overcome the strains and stress which are incident to surgical interference by not overloading with a potentially toxic anesthetic agent. To emphasize the theory of Selye,[11] the anesthetist can aid the general adaptation syndrome of the patient by allowing him as full use as possible of his normal physiologic protective mechanisms. With this idea in mind, it would appear that the present trend of using small amounts of several agents judiciously, each to accomplish its own purpose, and each interfering with the normal physiologic processes to a minor degree, would tend to permit the patient to make use of his defenses to the maximum advantage against the surgical insult to which he is exposed.

Summary and Conclusions

A new method of analgesic technique for the poor-risk patient undergoing thoracic surgery was tested in 100 patients. The analgesic state affords protection to the patient against disturbances of the physiological balance and the effects of the surgical trauma. Although this method of anesthetic management may appear complex, it provides and maintains conditions which are not possible with simpler approaches. The merits of this particular analgesic technique may be listed as follows: 1. The anesthetic agent and supplemental drugs used are almost universally acceptable to all patients. 2. There is minimal disturbance of physiologic mechanisms. 3. A relatively wider margin of safety for the patient and optimal working conditions for the surgeons are provided. 4. There is a relatively shorter and uneventful postoperative course.

The eventual acceptance of this technique by the competent and capable anesthesiologist can only be realized through an open-minded evaluation. However, we would like to emphasize that this particular technique is not for the novice whose knowledge and training in anesthetic management may be considered as inadequate.

THE ROCHESTER, N. Y., HEALTH FORUM

A SUCCESSFUL ADVENTURE IN PUBLIC RELATIONS WITH USE OF TELEVISION

Edward H. Townsend Jr., M.D.
and
Theodore B. Steinhausen, M.D., Rochester, N. Y.

For success in establishing a public health forum it is not enough to choose timely subjects, engage competent speakers, and secure excellent publicity. Data show that the public wants to hear about medicine from the medical profession and that the profession can retain control of publicity, provide subjects and personnel for the program, and remain the sponsor while holding the financial outlay to a minimum. The panel type of program here described was the most successful and easiest to prepare. The participants appeared on television cognizant of their subject, and tape recordings of the rehearsals enabled each to hear the full effect of his own role as well as that of the program as a whole. Experience makes it possible to adapt the program to local conditions, and this endeavor can be rewarding alike to the public, the profession, and the individual participants.

Due to the role played by publicity and advertising in modern life, the medical profession has inadvertently come to be used to further many commercial products and even quasimedical ideas. This and other factors have made the need for a better understanding of the medical sciences by the public more essential than ever. Toward this end several attempts have been made in many geographically dissimilar areas to hold "health forums," but most of these were sponsored by newspapers—not by the medical profession. Newspaper and magazine coverage is and always will be essential to the success of any public program in health, but their role should not become that of the sponsor. The medical profession should remain the sponsor, and on this basic premise the Rochester (N. Y.) Health Forum was founded.

Six years ago it was our privilege to be assigned by the Rochester Academy of Medicine and the Monroe County Medical Society to the task of establishing a public health forum for the dissemination of medical knowledge by local members of the medical profession to the regional public. During these six years, the chairmanship of the governing committee has changed to include several physicians and over 35 television programs have been presented. This continuing success warrants a review of the evolution of this program.

First Phases

In the formation of the Rochester Health Forum, the successful public health forums held in Atlanta, Ga., Dade County, Florida, Detroit, and Buffalo were studied. They seemed to possess one common weakness; each required the public to come to the profession. At this time (one year prior to the founding of the Rochester Health Forum) a public meeting, "Gamma Globulin and Poliomyelitis," was held in the auditorium of the Rochester Academy of Medicine at the height of the subject's emotional appeal to the public. The panel was composed of individuals popular in medical, civic, and political endeavors. The publicity was excellent. The attendance was most discouraging.

As its first program, the Rochester Health Forum again dealt with the subject of poliomyelitis at the inception of the vaccine program and at the peak of incidence not only of the disease but also of the fear. Yet, even with excellent news coverage and publicity, the employment of a locally popular radio, television, and newspaper figure as moderator, and the use of a central auditorium, a very small audience appeared. A second public presentation was presented that same year with the cooperation of a large local chapter of a nationa labor union—one of the few meetings betwee medicine and labor which have dealt purely wit the professional aspects of a medical subject. Th subject was "Cancer." Weeks of preparation, including advance publicity and questionnaires, gav the panel an audience of 900 persons. But such a approach is not applicable to many groups or locales. At the outset, therefore, it became apparent that the public relations of the medical profession would need to invade more aggressively the public media—in this age it centers around television. It was not intended that these forums should replace the constant necessity of physicians availing themselves of all manner of opportunity to present the profession to such small groups as parent-teachers associations and service clubs. These personal appearances remain as essential as at any former time.

The Federal Communications Commission, in licensing television stations, subjects the applicants to a thorough and cautious investigation to insure that the licensee will serve the public interest, convenience, and necessity. Thus, a certain percentage of television time comes to be given to "public service" programs. With this in mind, WVET-TV, a local station, was approached on the possibility of obtaining "free" television time. They were and have remained most cooperative. Thus, the audience, as judged by audience rating surveys, rose rapidly to viewers of over 50,000 television sets. One survey showed that the television program of the Rochester Health Forum had a greater audience than President Dwight D. Eisenhower at the height of his 1955 campaign. This is cited simply to show that the public wants to hear about medicine from the profession. The financial outlay by the medical societies concerned was held to a minimum, and the profession retained control of its publicity.

Thus, the medical profession assumed the offensive in television, and concurrently the television station discovered that this type of program had [redacted] appeal. A successful joint effort was d a smooth working team developed, putting on monthly television shows of er for eight consecutive months each shows are given during the summer The publicity personnel of the television proposed the title "House Call" for the y one-half hour television programs. The l profession continued to provide the sub- d personnel for the program. The television provided the necessary artistry, audiovisual d managerial personnel, while allowing the l profession to retain directive authority.

The Panel Presentation

In the first years, many different types of presentation were attempted. The most successful and easiest to prepare proved to be the panel type. The moderator of the panel may be a physician or a lay person, but he must be carefully chosen, since it is e who must unite the speakers into a coordinated resentation and keep the tempo of the show movg at a pace appealing to the viewers. The number speakers best managed is four, which allows ch speaker ample time to cover his phase of the subject. A few minutes is used for formal presentation of his subject (about one-half the allotted video time), followed by a question and answer period during which the speaker amplifies this subject. This latter period continues even during the "sign off," avoiding the awkward and time-consuming preparations necessary for a perfectly timed poignant end. Thus, the subject matter, rather than the mode of presentation, can be rehearsed.

During the developmental phase of the Rochester Health Forum, questions on the subject to be presented were solicited from several sources and presented to the panel in various manners. After these experiments, it was decided that physicians aware of the questions asked of them on the subject presented could instruct the moderator to ask the panel these several obvious questions. It is important, though incidental, and significant that the Rochester Health Forum has continued to solicit questions from any and all sources, whether the program be public or televized. At no time has the profession regretted this pledge or been embarrassed by the assumption of such a task.

Whatever the choice of the program personnel, it is important that they appear on television cognizant of their subject and its presentation. Sufficient advance notice must be given so rehearsals can be adequate not only for each physician but for the group as well. The Rochester Health Forum found it helpful to tape record rehearsals in order for one to hear the full effect of one's own role as well as that of the program as a whole. In these past six years, the Rochester Health Forum has utilized the services of over 100 physicians in the programs, distributing the load of public relations over the members of the profession.

Subject Matter

Any subject, or any phase of a subject, can be dealt with. The point or "message" of each show must be simply stated and clearly presented. For instance, with a program on congenital heart disease one could make a great many points—and yet by examples the message of one particular program was that some, not all, persons with congenital cardiac disease have correctable defects and that your physician is the one to help you decide. It is important to stress "your physician" and to censor the program so that one does not commit the profession as a whole to a course of action given by one physician-speaker.

One can maintain clear differences of opinion on a subject, and one can truly say what medicine does and does not know. One need not be a constant optimist. Over the years many letters have been received commending the Rochester Health Forum on the manner in which the truth about medicine has been presented.

Also, one can implant many incidental ideas into the audience, i. e., the role of the hospital interns and residents in modern medicine. One oft-quoted comment during the television show on "Childbirth" demonstrates this point. One of the panelists, while speaking of the role of the intern, said: "Remember the intern who assists me today may deliver your daughter tomorrow."

This is true good public relations. As a matter of fact, to lighten one year's program the Women's Auxiliaries of the Monroe County Medical Society and the Rochester Academy of Medicine were allowed to put on a Christmas show. This met with considerable success. It also pointed up the important role played by the wife and family in every physician's life.

Health forums cannot be commercially sponsored. All physicians are aware of the poor showing a now defunct television program gave the profession between the "commercials." The sponsor of health forums must remain the medical profession.

Comment

The Rochester Health Forum is run by a committee small enough to be useful and yet sufficiently large to handle the several chores. The officers have had their tenure of office staggered so that some continuity to the over-all program can be maintained. The function of the committee is not only to produce the shows but also to insure advance publicity and notices and to constantly appraise each show for its full effect on the audience and the profession. To assist in the establishment of the Rochester Health Forum, we served as co-chairmen of the committee for three years.

Each locale will have its own ground rules and *modus operandi*, but it is hoped that by setting forth this experience others might be encouraged to enter the field of public relations. This endeavor has proved to be rewarding to all individual physician participants and valuable to the medical profession. Incidentally, the combined cost of this enterprise to both sponsoring societies is less than $1 per physician per year.

EVALUATION OF THE NEWBORN INFANT—SECOND REPORT

Virginia Apgar, M.D., Duncan A. Holaday, M.D., L. Stanley James, M.B. (New Zealand),
Irvin M. Weisbrot, M.D.
and
Cornelia Berrien, A.B., R.N., New York

The condition of each newborn infant was expressed by a score, the sum of five numbers obtained within 60 seconds after complete birth. The numbers were determined by objective observations of heart rate, promptness and vigor of the first respiratory efforts, and reflex response to certain stimuli, muscle tone, and color. The highest possible score was 10, representing the optimum condition of the infant. The predictive value of such scores is here established by a study of the scores of 15,348 infants, for the death rate among infants scoring 2, 1, or 0 was 15%, while that for infants scoring 10 was 0.13%. The score was found to be a measure of the relative handicaps suffered by infants born prematurely, delivered spontaneously at term, delivered by cesarean section, or subjected to other obstetrical and anesthetic hazards. The lower scores were generally associated with chemical findings characteristic of asphyxia in the blood obtained by umbilical catheterization. The score was especially useful in judging the need for resuscitative measures, such as respiratory assistance.

In 1952, a scoring system was devised to evaluate the condition of infants born at the Sloane Hospital for Women.[1] Its use has increased yearly in various clinics. This report will discuss the incidence of the scores of 15,348 infants, the corresponding death rates, the relation to biochemical studies, and considerations for improving the system. The adoption of this method by the Collaborative Study of Cerebral Palsy has resulted in valuable criticism from other clinics using it for the first time.

The incidence of scores, in all types of deliveries, does not vary significantly from that found in two previous reviews[2] (fig. 1, *top*). Approximately 6% of the infants were severely depressed, 24% moderately so, and 70% were in excellent condition. The incidence in the three major types of deliveries, vaginal vertex, cesarean section, and breech, varies greatly (fig. 2). Over 20% of infants delivered by breech presentation fall in the severely depressed group, while only 12% of those by cesarean section and 3% of those by vaginal vertex delivery score 0, 1, or 2.

The over-all death rates were the same as with a smaller number of patients (fig. 1, *bottom*); 15% of groups 0, 1, and 2 died. When subdivided according to type of delivery (vaginal vertex, 1.4%; cesarean section, 3.8%; breech, 13.3%), breech deliveries showed the highest mortality (fig. 3). This is directly related to prematurity. While 35% of the infants delivered by breech presentation at Sloane

Hospital were between 500 and 2,500 Gm. (1 to 5.5 lb.), 90% of the deaths were in premature infants.

Since the majority of neonatal deaths occur in premature infants, it was thought wise to examine the scoring system with special emphasis on this group. The following graphs show that the incidence and the death rates of the various scores follow a pattern similar to the entire group (fig. 4).

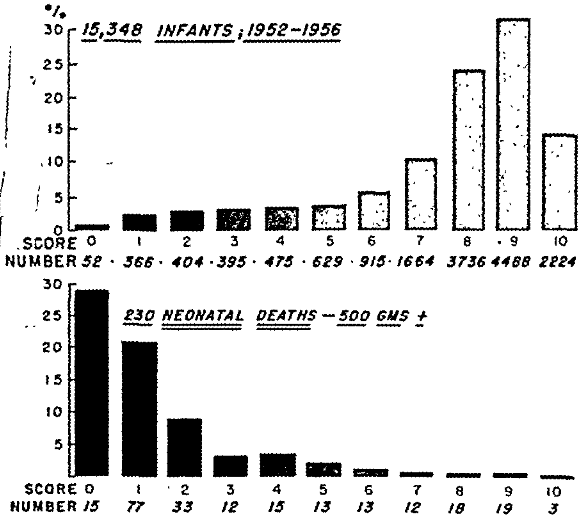

Fig. 1.—Distribution of scores in evaluation of newborn infants in all types of deliveries (*top*) and in evaluation of newborn infants and neonatal deaths in vaginal vertex delivery and cesarean section (*bottom*).

The scoring system has been used as a guide to the need for resuscitation. Since the death rates dropped quite sharply after a score of 4 in the preliminary study, we have used a score of 4 or less as an indication to assist ventilation. During the past two years, we have had an opportunity to check this clinical impression with biochemical studies immediately after birth and can relate the findings to the score.[3] Since the arterial blood of one-quarter of the vigorous infants was 10% saturated or less, it soon became evident that oxygen values alone had no relation to the clinical condition of the infant. However, no infant with good oxygen values in his arterial blood was depressed. If, in addition to hypoxia at birth, an elevated tension of carbon dioxide, a low pH, and low buffer base value existed, the infant was severely depressed.

After using umbilical arterial samples as a better reflection of the infant's condition than umbilical vein blood, it was decided that blood obtained from inside the baby by umbilical catheterization gave the truest values. The methods used have been reported previously[3] and detailed chemical findings presented to th of another communication. In sum- these experiment every instance the pCO_2 in the aware of the questi an in the umbilical artery. Like- presented could ins buffer base values were lower in blood taken from within the infant. All these findings point to the rapid development of respiratory and metabolic acidosis during and immediately after birth.[4] Whether or not these conditions are detrimental to mental and metabolic development remains to be proved, but they can hardly be desirable. The findings stress the importance of prompt treatment by the simple process of ventilation. Intentional delay during the course of delivery is not to be condoned.

With a few exceptions, the more asphyxic the blood values, the lower the score one minute after birth. Using the buffer base value as the measure of the duration of asphyxia, the value in infants with scores of 4 and lower was 29.3 mEq. per liter, while those with scores of 8, 9, and 10 were 36.6 mEq. per liter. This is statistically significant ($p < 0.001$) (fig. 5).

The exceptions remain to be explained and in general are related to the type of anesthesia and medication administered. It has been shown previously that the babies born after use of regional anesthesia in the mother are more vigorous than after a general anesthesia, though skillfully administered.[5] The explanation probably depends on the action of general anesthetic agents in the presence of asphyxia. The drugs used for regional anesthesia may pass through the placenta but do not appear to augment the asphyxic depression of the infant.

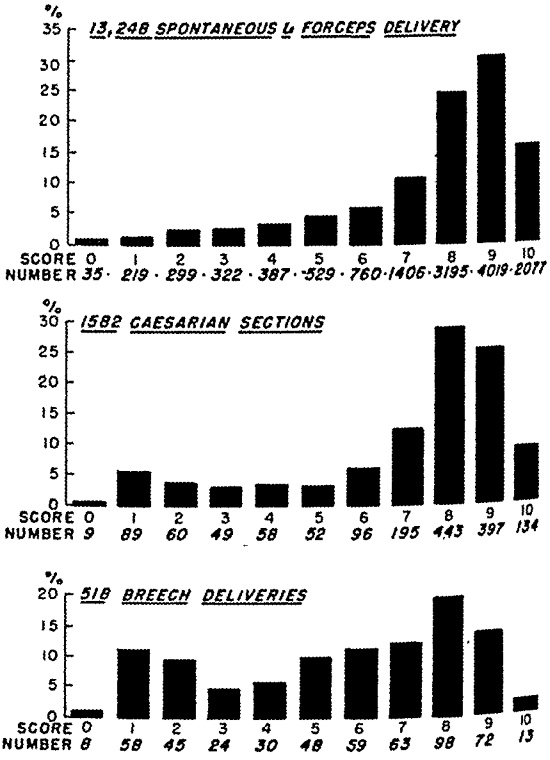

Fig. 2.—Incidence of scores in evaluation of newborn infants in three major types of deliveries.

Three patients with scores of 2 or 3 showed buffer base values well above the average. All three mothers were given anesthetics by inhalation. It is likely that their low scores were due to reversible drug depression, rather than deranged acid-base balance.

Two other patients, with a score of 6, had buffer base values below the average for that score. One of these mothers received spinal anesthesia for delivery of a distressed infant with impacted shoulders. Eighteen minutes elapsed before sustained respiration. The other was a breech delivery of moderate difficulty, with cyclopropane as the anesthetic.

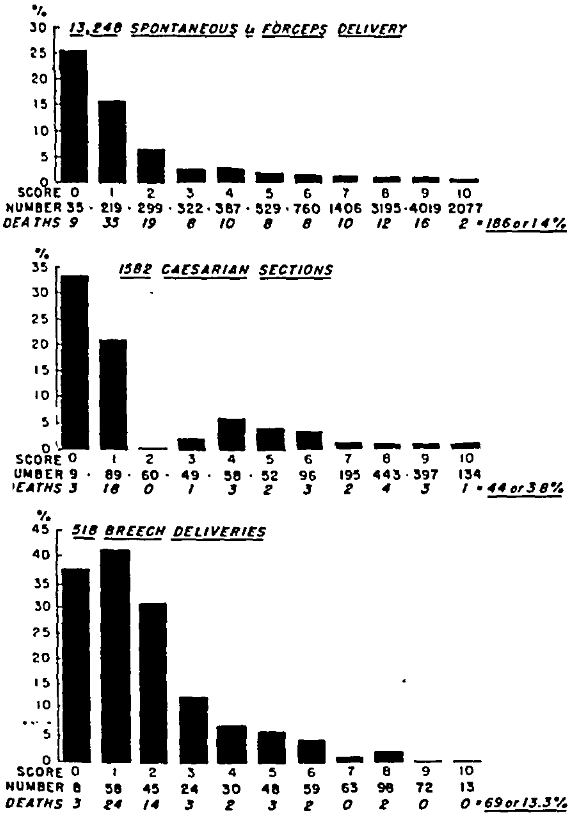

Fig. 3.—Incidence of scores in evaluation of newborn infants and neonatal deaths in three major types of delivery.

Practical Considerations in Using the Scoring System

After a year's trial with two individuals deciding on the score at various intervals after birth, it was decided that 60 seconds after the entire birth of the infant, irrespective of delivery of the placenta, represented the time of most severe depression after birth. In the Sloane Hospital the cord has been cut by this time, and the infant is in the hands of an individual other than the obstetrician. In many hospitals, such is not the case. Those obstetricians who practice slow delivery and delayed cl of the cord until pulsations of the umbilical cease still have the infant in the sterile field. ever, if the obstetrician is reminded of the p of time by another observer, he may assign a s even though the cord is still attached. Two po are given for each of the following vital sign color, respiration, muscular tone, nasal irritabilit and heart rate. All infants with a score of 8, 9, c 10 are vigorous and have breathed within seco of delivery. In this group, scores of 8 or 9 re a lower score for color. The infants with a score of 4 or less are blue and limp and have failed to establish respiration by one minute. With increasing depression the last two vital signs, reflex irritability and heart rate, disappear in that order.

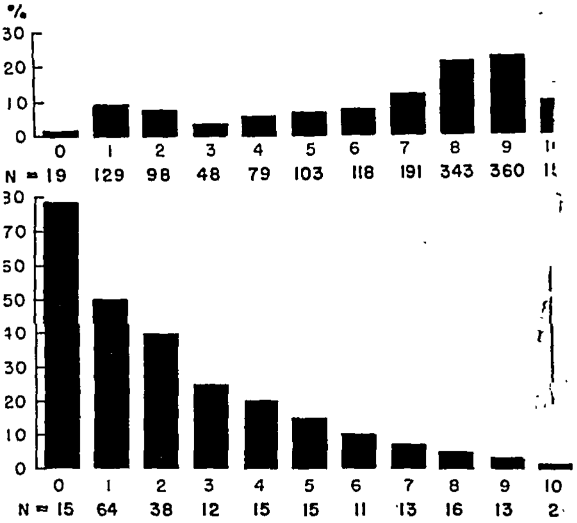

Fig. 4.—Distribution of scores in evaluation of 1,642 pr mature infants (*top*) and of 214 neonatal deaths in prema ture infants weighing 500 to 2,500 Gm. (1 to 5.5 lb. (*bottom*).

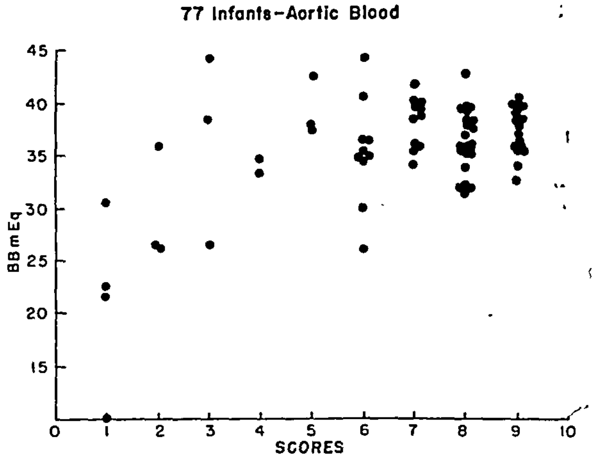

Fig. 5.—Relation of buffer base values to scores in evaluation of aortic blood from 77 newborn infants.

six years of experience, the method has und simple to teach to any personnel regu- the delivery room, whether obstetricians, siologists, pediatricians, medical students, duate or student nurses. Whoever has the directly in his care at one minute can best n the score. When two or more people decide ndently, we find a range of one value above below a decided score to be the widest varia- n. This occurs chiefly in the mildly depressed up, i. e., score 5, 6, 7. Variation is rare in in- ts with high or low scores. There is also less riation if the score is decided quickly.

In clinics where delayed clamping of the cord routine, the test for reflex irritability with nasal heter is not satisfactory. Also, when the infant ving lustily, a sneeze may not be seen. A brisk ntial slap of the soles of the feet has been to be a simpler and more effective method ng this response. A cry is given a value of grimace or movement a value of 1, and no

eaction, 0. Although the catheter may not be used o test reflex irritability, it is of value in the delivery room diagnosis to exclude atresia of the nose, sophagus, duodenum, jejunum, or rectum.

All criteria are not of equal importance. With he introduction of the scoring system, it was felt hat if each of the five criteria was weighted with a formula to give it proper significance, the system would become so complicated that it would not be used at all. Our first effort was to have the evaluation system used widely. Recently, after reports from individuals[6] and from advisory board of the National Institute of Neurological Diseases and lindness as to the relative value of the five criteria, there is no doubt that the first two, heart rate and respiratory effort, are much more important than the next two, muscle tone and reflex irritability. Color is of the least importance. There is no objection whatsoever to revising the numerical situation to provide more accuracy, but deviations from the original scoring system should be clearly stated in such reports.

Muscle tone evaluation is performed visually. The tonus of a well-flexed infant is as obvious as the absence in a completely flaccid one. Anything in between receives a value of 1, rather than 2 or 0. With the recent fortunate increase in personnel in the delivery room, due to the National Institutes of Health program in 16 cooperating hospitals, objective measurements of muscle tone have been undertaken. To date, we are unfamiliar with the value of these detailed observations.

Serial scoring is of value. Although we have no statistics to prove the clinical impression as yet, it appears that the longer a low score stays low, the worse the prognosis for survival. If a score of 0, 1, 2 does not improve by 15 minutes, the prognosis is extremely grave. Only occasionally does a good score, such as 8, 9, 10, drop after one minute. This is almost always associated with enthusiastic efforts to aspirate the pharynx or to empty the stomach too soon. The cause is usually from the catheter tip touching the vocal cords, in a vigorous infant, and causing reflex laryngospasm. Other causes are respiratory obstruction or hypoventilation from drug depression. These complications are completely preventable.

A working plan for the scoring system is presented below. The only changes from the original chart are the omission of the word "irregular" to describe respiration and the new method for testing reflex irritability.

Summary

The incidence of scores and death rates in the evaluation of 15,348 newborn infants at the Sloane Hospital for Women varies in the three major types of deliveries: vaginal vertex, cesarean section, and breech presentation. This method of evaluation is useful in analyzing premature infants. Biochemical evidence corroborates the value of this scoring system. The infant is evaluated according to color, respiration, muscular tone, irritability, and heart rate.

LOWERING BLOOD LIPID LEVELS BY CHANGING FOOD PATTERNS

Helen B. Brown, Ph.D.
and
Irvine H. Page, M.D., Cleveland

It is agreed that the reduction of the incidence and severity of atherosclerosis might depend, in part, on a reduction of the amount of animal fat in the national diet. Substitutes must be found for the foods that are to be avoided. The use of vegetable oils makes it possible to provide much the same kinds of food to which people are accustomed, and foods so prepared require no individual preparation for the patient since they are suitable for the whole family. This was demonstrated first by a 21-day test in four active young physicians and later by a study, continued for 6 to 24 months, in 16 patients with atherosclerosis. The principal source of fat was a mixture of 94% cottonseed oil, 1.5% monostearin, 1.5% distearin, and 3.0% tristearin. Data on serum cholesterol levels showed that the food pattern here described reduced the serum cholesterol levels in normal and in many hypercholesteremic people. In some it was more effective than the low-fat diet. The food pattern is sufficiently developed to suggest its use on a larger scale.

There is strong circumstantial evidence that the evel of blood cholesterol is causally associated ith the incidence and severity of atherosclerosis. he level in turn may be in part controlled by the uantity and quality of fat in the diet. While neither f these propositions has been proved,[1] enough is nown to suggest the value of wider spread experinents to determine their validity.

The recent finding that the serum cholesterol evel may be reduced by some unsaturated vegeable oils[2] makes such a test at least possible. Up o the present, use of these oils has largely been in formula diets[3] and not very palatable mixed diets.[4] Further, the experiment was almost by necessity short-term because the diets were not prepared for long use.

While this is not the time for radical change in the diet of the public, most investigators would agree that a reduction in the amount of fat in the diet is desirable. There are, however, groups of patients that include those with family history of premature heart attacks, overt hyperlipemia, or both, in whom a special diet or, much better, a "way of life" is a therapeutic necessity. The latter group has been our first concern, but with experience gained it has become evident that the objective of lowering the serum cholesterol level and avoiding obesity can be achieved with foods prepared in most cases quite as palatably as is current practice.

Food Patterns

Diet has become an unfortunate word. It means to most people weight reduction or a hospital diet, restrictive and unappetizing. The dictionary is kinder to the word: it comes from the Greek *diaita,* a manner of living. And so diet involves not only food but the attendant human values of conversation, companionship, and aesthetic satisfaction. Tamper with a man's food and you tamper with the basic pattern of his life.

It has been our hope that a way of life may be evolved which will slow the rate of development of atheroma with its attendant heart and brain disease. To attempt this we realize that first we must think in terms of individuals before populations. The individual must be able and willing to follow the recommendations in his business and social life without making food the main concern of existence.

An acceptable food pattern requires that foods be readily purchasable, easily prepared, suitable for the whole family, and adaptable to varied cultural backgrounds. A simple prohibition of foods without the offer of something else as satisfying is futile. Witness the 6% rise in cigarette consumption after warnings against lung cancer and heart disease.

Serum cholesterol level may be reduced by two essentially different diets. One is the strict low-fat diet and the other is a diet containing a minimum of animal fat along with sufficient vegetable oil to provide a normal total fat intake. The low-cholesterol diet is essentially one low in animal fat and is not considered separately here.

These two intrinsically different diets, unfortunately, are sometimes misinterpreted as being interchangeable. The low-fat diet omits as much of all fats as possible from all food sources. It provides only 10 to 15% of the total calories as fat, most of which is animal fat (table 1). The vegetable oil diet is basically the low-fat diet with the addition of vegetable oils. This diet substitutes vegetable oil for most of the animal fat eaten in a normal diet. It is important to stress the substitution of one kind of fat for another. The addition of a few tablespoons of oil to a basically normal food pattern

---

From the Research Division of the Cleveland Clinic Foundation and the Frank E. Bunts Educational Institute.

in which 42% of the calories is animal fat (and hydrogenated vegetable oil) will not lower the serum cholesterol level.[5]

Low-Fat Diet.—Our version of the low-fat diet contains 30 Gm. of fat daily. This is mostly animal fat, and substantially all of it is eaten at one meal as suggested by Wilkinson.[6] The low-fat diet eliminates fat—containing dairy products, table (butter and margarine) and cooking (lard and hydrogenated shortenings) fats, egg yolks, and nuts. Intake of meat fat is reduced by avoiding pork and by use of lean beef instead and by frequent use of veal, poultry, and fish. By having the meat fat all in one meal, not only the catabolism of fat may be more complete but also the person is assured of one satisfying dinner each day. For the fat-free lunch, low-fat (less than 1 Gm. per serving) fish and poultry are suggested. Other practical suggestions include low-fat cookery, low-fat recipes, and lists of low-fat foods and meats. A list of meats, usually obtainable in restaurants, is included, which will provide no more than 5 Gm. of fat. Such recommendations have been collected in a low-fat cookbook, mimeographed and furnished to each patient.

TABLE 1.—*Composition of Normal, Low-Fat, and Vegetable-Oil 2,000-Calorie Diets*

Composition	Type Diet		
	Normal	Low-fat	Vegetable-oil
Fat, Gm.	90	30	90
Animal	66	15	15
Hydrogenated	11	15	0
Vegetable oil	13		75
Protein, Gm.	60	70	70
Carbohydrate, Gm.	235	363	225

This low-fat diet has been followed successfully at home, at work, and at play. However, in spite of these suggestions, the diet tends to become monotonous after a year or so. It is a diet in the unpleasant sense of the word because its variety is limited. There are currently few commercial food products which meet its requirements. The production of more such foods should be a challenge to the food industry.

Vegetable Oil Food Pattern.—Addition of vegetable oil to the low-fat pattern makes possible greater variety and palatability. Our current vegetable oil pattern is composed of carbohydrate, 45% of the calories, protein 14%, and fat 41%. Seven per cent of the calories derive from meat and 34% from cottonseed oil. Thus, for example, a daily intake of 2,000 calories consists of 225 Gm. of carbohydrate, 70 Gm. of protein, and 90 Gm. of fat—meat providing 15 Gm. of fat and vegetable oil 75 Gm.

This pattern is similar to the food pattern followed by Americans, in which 85% of the fat is from animal and hydrogenated fats and 15% from vegetable oils (table 1).[7] Vegetable oil replac animal fat in this food pattern; 17% of the fat is animal and 83% of vegetable origin.

One chemical characteristic of fats is measur by their iodine value, which indicates their deg of unsaturation. Animal fats, the popular hyd genated shortenings, and tropical nut oils such coconut oil and cocoa butter are relatively hig saturated and have low iodine values (10-80). Sal nut, and seed oils contain a large proportion unsaturated fatty acid, primarily linoleic, and h high iodine values (105-138). Some of the unsa rated fatty acids are essential to the proper nu tion of rats and other mammals. Linoleic acid is "essential fatty acid" which is not synthesized the body and must be supplied in the diet.

The degree of saturation of an individual determines the effect on the serum cholesterol le when the fat is taken as the only source of diet fat, as in so-called formula diets.[3a] Saturated f with iodine values below 90, such as those pres in dairy products, meats, eggs, margarines, and hydrogenated shortenings, tend to increase the serum cholesterol level; relatively unsaturated vegetable oils with iodine values above 90, rich in linoleic acid, tend to decrease the serum cholesterol level. When saturated and unsaturated fats occur together in the diet, the hypercholesteremic tendency of each gram of saturated fat can be counteracted by about 3 Gm. of unsaturated fat.[3b] Serum cholesterol level reduction occurs when the unsaturated fat supplies from 30 to 40% of the calories in the diet.[8] But such oils have little effect when taken in addition to the usual amount of saturated fat present in normal American foods.[9] These facts have been determined by special "formula" diets or by carefully controlled diets of mixed foodstuffs. Valuable as they are in tests, such diets are unpalatable and impractical for common use. We have tried to transform the diet formula into an appetizing and varied food pattern.

Practical Administration of Vegetable Oil Food Pattern

Reduction of Saturated Fat in Food Pattern.—One of the most serious problems to the cook is how to limit animal fat and yet provide adequate amounts of high-grade protein. We have solved the problem by substituting protein foods low in animal fat for those high in it. Much of this fat can be avoided by eliminating butter, whole milk, cream, cheddar cheese, egg yolks, and products containing these in quantity. Skimmed milk, dry cottage cheese, and egg whites, each in varied forms, provide first quality protein.

Fat in meats, fish, and poultry varies from less than 1 Gm. to over 30 Gm. per serving. Meat fat can be kept to 15 Gm. a day, as suggested for the low-fat diet, by proper selection of meats. We have listed the meats for our patients according to the fat provided per serving, including a list for restaurant use. These choices do not affect the normal quantity or quality of the protein while still limiting the saturated fat intake.

Further reduction of saturated fats is accomplished by avoiding oleomargarine, hydrogenated shortenings, coconut, chocolate, cocoa, and foods made from them. The same low-fat cooking techniques used for the low-fat diet also contribute to reduction of saturated fat in the vegetable oil food pattern.

Substitution of Vegetable Oil for Animal Fat.—Cottonseed oil and soybean oil are the only oils with the proper chemical characteristics for use in the vegetable oil diet, which are, at the same time, available in sufficient quantity in the United States for common use.[10] Others, such as corn and peanut oil, which have proved valuable for serum cholesterol reduction, are marketed only in small quantities.

All fats and oils produced for food in the year 1955-1956 in the United States amounted to a little more than 10 billion pounds.[10] Over half of this was comprised of unsaturated oils in the following proportions: soybean oil, 31.1%; cottonseed oil, 18.7%; corn oil, 2.7%; and peanut oil, 0.7%. Corn oil is already near the peak of production possibility. One bushel of corn produces only 0.75 lb. of oil as compared with 11 lb. from a bushel of soybeans. If all the corn raised in the year cited had been diverted to corn oil food products, it would have supplied only 7% of the total edible fats produced in that year. Obviously any widespread use of oils would require the utilization of cottonseed and soybean products.

We have used a "modified" vegetable oil, prepared for this study by Dr. Fred H. Mattson of the research and development department of Procter and Gamble Company, which will be referred to as "M." It consists of 94% cottonseed oil, 1.5% monostearin, 1.5% distearin, and 3.0% tristearin. About 11 to 21% of these additives are absorbed.[11] This shortening can be made into a spread for bread, can be used as shortening for baked goods, and will emulsify in a blender with nonfat milk solids to yield reconstituted "milk," "cream," or "ice cream," of any desired fat content. The advantages of "M" over commercial cottonseed oil are its blandness and this ability to emulsify. But no special product is necessary for the vegetable oil food pattern. Commercial corn, cottonseed, or soybean oils are excellent for cooking and baking. Two or three teaspoons of such oils added to each serving of a low-fat food converts it to a satisfying, flavorful product. These uses are in addition to their more common use as salad oils.

We have not yet determined the dietary effect of natural foodstuff containing vegetable oil, such as nuts, on the serum cholesterol level. Fried foods have also been avoided because the amount of oil absorbed by them and the chemical changes which occur during frying are both uncertain. These problems are under study.

Research Kitchen and Patient Instruction.—The practical aspect of our dietary project center is the special research kitchen (Mrs. Jean Perry Spodnick, dietitian in charge; Miss Margaret Foust, head of the Cleveland Clinic Hospital dietetics department) where weighed meals are prepared, low-fat cooking methods tested, sample dishes prepared for fat analysis (Mrs. Ann Wahl Scanu, in charge), and recipes tested and developed. We have borrowed recipes and ideas from many sources.

Our continuing search is for desirable substitutes for the foods which must be avoided. Large appetites can be satisfied with large servings of veal, fish, and poultry. We have attempted to obtain the patient's cooperation by removing the feeling of guilt when home or business circumstances make the food pattern difficult to follow. A full discussion of such circumstances has often provided a solution for the difficulties.

TABLE 2.—*Vegetable-Oil Diet Pattern and Sample Menu Served in Tests*

Food Pattern*	Menu for June Day
Breakfast	**Breakfast**
Fruit, 1½ servings	Melon
Cereal, 100 Gm.	French Toast (made with egg white)
Bread, 45 Gm.	Maple Syrup
Spread, 50% "M", 10 Gm.	Spread
"Cream", 20% "M", 60 Gm.	Skim Milk
Skim Milk, 150 Gm.	Coffee
Sugar, 10 Gm.	"Cream"

"M" oil, in cooking, 20 Gm.	
Sugar, 10 Gm.	

* Food pattern supplies about 2,500 calories. Amount of animal fat and "M" oil are kept constant each day. Fruits, vegetables, and cereals are interchanged, as shown in sample menu.

Instruction includes the serving of several meals from the research kitchen, demonstrations of the preparation of special "M" products, and presentation, with discussion, of our "Vegetable Oil Diet Instruction and Recipe Book." Individual monthly conferences give us a good estimate of how well the food pattern is being followed. At this time the patient is weighed, his blood sample taken for analysis, and his problems discussed with physician and nutritionist.

Advantages and Disadvantages of Vegetable Oil Food Pattern.—Use of vegetable oils makes it possible to provide the same kinds of food to which people are accustomed. Vegetable oil foods require no individual preparation for the patient, since they are suitable for the whole family. They allow added calories to be supplied easily, which is an advantage over the low-fat diet.

The principal disadvantage is that the usual commercial foods are not necessarily prepared with vegetable oil, and hence more home cooking is necessary. Dinners out with friends and restaurant meals present problems. These disadvantages are common to all special diets. In this regard, vegetable oil food recommendations resemble a therapeutic diet rather than a food pattern.

TABLE 3.–*Dietary Components and Sources of Fat and Protein Used in Diet Tests*

† Fat contained in cereals, fruits, and vegetables.

The greatest danger to the logical development of an effective food pattern is the premature claims for the virtues of any one particular feature of the food pattern without proper evidence to back it and the rush to capture the market with preparations of still unproved value. The many inevitable failures will not increase public confidence in those changes which might be desirable.

Vegetable Oil Food Pattern

The effectiveness of this food pattern for reducing the serum cholesterol level was demonstrated both in two-to-three-week weighed diet tests in which the subjects ate all their meals from our diet kitchen and in two to eight months continuing trial of the food pattern at home. Many patients were subjects of both the diet test and the home trial.

The weighed diet tests supplied an average of 44% of the calories as carbohydrate, 14% as protein, and 42% as fat, with sufficient calories to maintain weight. The fat content of the foods was determined by analysis [12] as follows: meat, 4% total calories; "M" oil, 33%; and all other foods, including fish, 5%. Table 2 gives an example of the types of food served.

Food supplies for the entire experimental period were stored before the test began, to insure uniformity. Bread was from the same baking, chicken from the same flock, meat from the same cut, and canned goods from the same pack. All food servings were weighed. Each lot of "M" spread and "cream" was analyzed by petroleum ether extraction [12a] basic food servings including fish were analyzed for fat after grinding, acid hydrolysis, and ether extraction.[12b] A sample of each meat serving was set aside for analysis and pooled according to the kind of meat and analyzed.[12b]

The test periods were from 11 to 21 days. Weight was recorded daily before breakfast and caloric intake altered to maintain the weight to within ± 2 lb. Food was completely eaten. The subjects were sufficiently cooperative to inform the kitchen of dislike of a single food so that a substitute could immediately be prepared. This rarely occurred. All subjects were encouraged to be physically active. The normal young men and women, employees of the Cleveland Clinic, carried on the usual responsibilities and social life. Some of the patients with elevated serum cholesterol levels came into the hospital on the convalescent floor but were out of doors daily. Others came in for all their meals to the research kitchen from their normal activities.

Blood samples were drawn at the beginning and end of the test as well as at five-to-seven-day intervals during the test. Total cholesterol level was determined in each sample and serum lipid fractions and lipoprotein levels ($-S_{1.21}$, or negative *sedimentation or flotation rate at density*$_{1.21}$, determined in the ultracentrifuge) at the beginning and end.

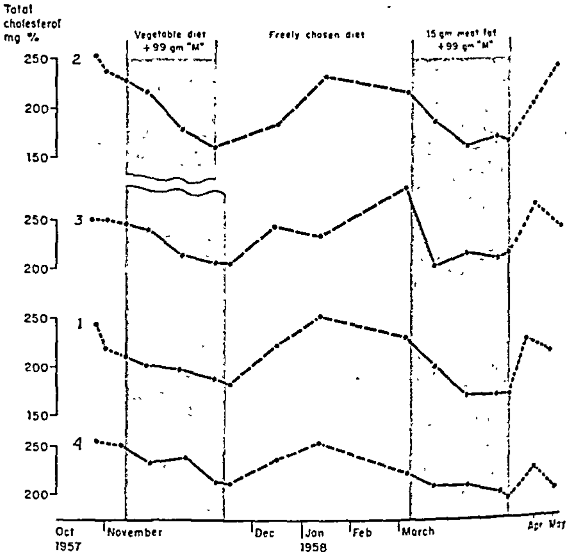

Fig. 1.–Serum cholesterol level changes in normocholesteremic individuals consuming vegetarian diet with "M" cottonseed oil and "M" vegetable oil diet pattern for 21-day weighed food test served from research kitchen.

Effect of "M" Oil on Lipids of Normocholesteremic Persons.–The "M" oil was made the only significant source of fat for a 21-day test in four active young physicians. Vegetables, fruits, cereals, bread, skimmed milk, egg whites, and "M" constituted the vegetarian diet (table 3). Serum cholesterol values were about 250 mg. per 100 ml. during the control period on freely chosen foods. These levels dropped 40 to 80 mg. by the end of the test period (fig. 1 and table 4). The lipoprotein pattern was normal and remained so; triglyceride fractions were approximately normal. Within 30 days after the test, when the subjects were again on freely chosen foods, the serum cholesterol had returned to its control level.

* Individuals are listed in ascending order of cholesterol concentration on normal diet. Periods of weight loss or fever are omitted from averages. All had normal thyroid function as judged by radioactive iodine uptake, and normal glucose tolerance test, except for diabetic patients.

† Key: 1, atherosclerosis—a, angina pectoris, b, cerebral, c, heart disease, d, myocardial infarction, e, obliterans, f, renal, and g, general; 2, diabetes; 3, familial hypercholesteremia; 4, fatty liver; 5, hypertension; and 6, xanthomatosis.

‡ Serum cholesterol level during 21-day weighed food test served from research kitchen.

§ Hypercholesteremic previous to coming to Cleveland clinic; on self-selected low-fat diet, estimated fat intake 40 to 60 Gm. per day.

‖ Cholesterol level determination done in another laboratory.

¶ 30 Gm. vegetable oil per day.

# 50 Gm. vegetable oil per day.

** 100 Gm. vegetable oil per day.

The same subjects underwent a similar test except that the diet contained meat, supplying 15 Gm. of meat fat in addition to the "M" oil (table 3). Again the cholesterol levels fell 40 to 80 mg. and returned to the preexperimental levels after 30 days on freely chosen foods (fig. 1).

Cottonseed oil "M" successfully reduced the serum cholesterol level well below that present in normal persons with a free choice of foods when the oil supplied 34% of the calories. This was also true when 15 Gm. of meat fat, providing 5% of calories was included in the diet in addition to "M" oil.

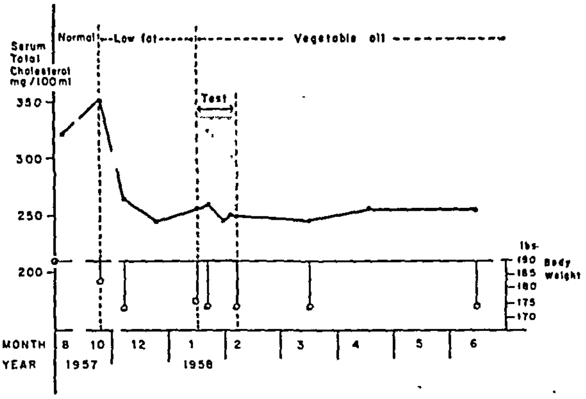

Fig. 2.—Normal cholesterol levels attained in patient receiving low-fat diet, maintained on "M" food pattern, including 21-day test period in which weighed foods were served from research kitchen (table 4, subject 12).

Vegetable Oil Pattern in Hypercholesteremic Patients.—Sixteen patients with atherosclerosis, among whom several had xanthomatosis, myocardial infarction, diabetes, and hypertension were studied (table 4).

Control blood samples were taken covering periods up to four weeks until there was reasonable uniformity in serum lipid values. These 16 have continued on our dietary study for 6 to 24 months.

Thirteen of these patients were placed initially on low-fat diets for 3 to 15 months, and then all were given the vegetable oil food pattern. The average serum cholesterol levels are given in table 4, the patients being arranged only according to their hypercholesteremia on freely chosen foods.

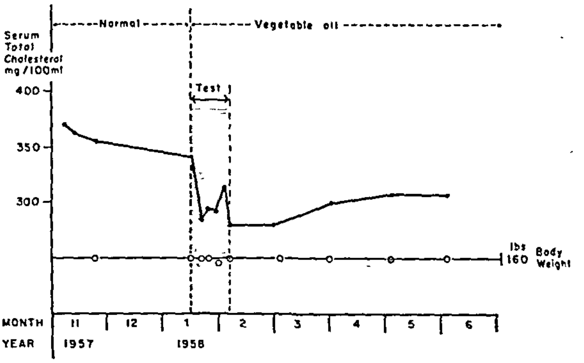

Fig. 3.—Normal cholesterol level attained in patient on "M" vegetable oil food pattern, including 21-day test period in which weighed foods were served from research kitchen (table 4, subject 14).

Cholesterol values of 300 mg. per 100 ml. or less were reached by three patients on the low-fat diet and were maintained on the "M" food pattern. An example is shown in figure 2. Normal values were attained by three other patients on the "M" food pattern alone (fig. 3). Four of the patients exhibited reduction of cholesterol levels, but not to normal, on the low-fat diet. The "M" food pattern brought their levels to normal. The values of one of these patients is shown in figure 4.

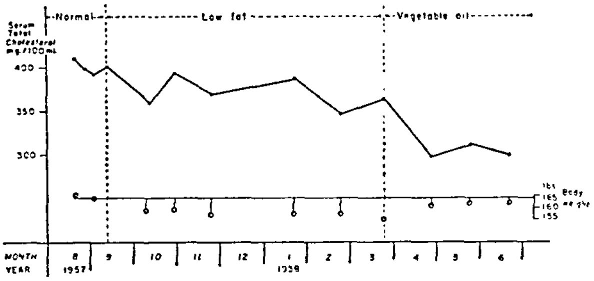

Fig. 4.—Slight reduction of serum cholesterol level on low-fat diet, and further reduction to 300 mg. per 100 ml. in patient on vegetable oil food pattern (table 4, subject 15).

High cholesterol values were still present in three patients, though the low-fat diet had produced some reduction. In these individuals the "M" food pattern did no more (fig. 5).

Elevated serum cholesterol levels fell promptly in the two diabetic patients on the "M" food pattern. The pattern was adjusted to their carbohydrate requirements, providing 33% of the calories as carbohydrate, 21% as protein, and 46% as fat (meat fat 5% and "M" 41%). One of the diabetics was changed to the low-fat diet because of weight gain. Cholesterol values did not rise. The one hypertensive, normocholesteremic patient had a drop of 100 mg. in serum cholesterol level on the "M" food pattern.

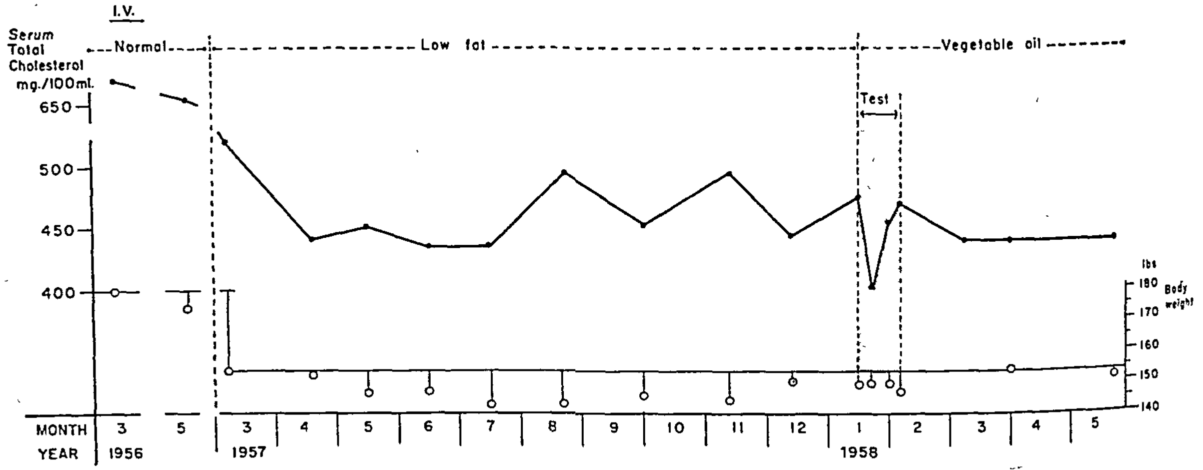

Fig. 5.—Hypercholesteremia persisting in patient eating low-fat diet and vegetable oil diet, including 21-day test period in which weighed foods were served from research kitchen (table 4, subject 21).

Both the low-fat and "M" food patterns effectively reduce serum cholesterol levels, but in some hypercholesteremic patients the "M" pattern exerts a greater reduction. A few patients with severe essential hypercholesteremia respond only moderately to either food pattern.

Elevated low density lipoprotein and triglyceride levels tend to be less effectively reduced than serum cholesterol levels. The triglyceride fraction, after an initial period of reduction, returns to its former level. These and other changes in lipid constituents will be reported in detail later with Dr. Lena Lewis and Dr. Harriet Dustan.

Comment

Reduction of serum cholesterol levels to or near normal was achieved by either a low-fat diet or the vegetable oil food pattern. Serum cholesterol levels fell within a few days or weeks with either type of diet. In some individuals the level was lower on the vegetable oil food pattern than the low-fat diet, *and in all individuals it seemed to be much more* steady (fig. 4 and 5). This steadiness is also demonstrated in patients who went off the diet briefly. One patient went on a fishing trip and ate whatever was provided, including fried fish daily. At the end of a week his serum cholesterol level had risen only 25 mg. Another patient treated himself to prime steaks for two weeks while on the "M" food pattern. His cholesterol level rose 40 mg., but on the low-fat diet, one day's indulgence in ham increased it 70 mg. Clearly, the serum cholesterol level is less variable with the vegetable oil pattern than with the low-fat diet.

A partial explanation for the action of these diets on serum cholesterol lies in the nature of the fat they contain. The normal food pattern supplies sufficient saturated fat to keep the cholesterol level relatively elevated. The low-fat diet reduces the saturated fat intake to an amount that does not affect the concentration of serum cholesterol, and so the cholesterol level is lower than on usual diet. The vegetable oil food pattern is effective in decreasing serum cholesterol level because it not only curtails intake of saturated fats below the hypercholesteremic concentration but also increases the intake of unsaturated vegetable oils to the extent that it exerts a hypocholesteremic action. This double action may be one explanation for the greater effectiveness of the vegetable oil food pattern over the low-fat diet in some patients and for the ineffectiveness of the addition of a few tablespoons of vegetable oil to a basically normal food pattern high in saturated fats.

The vegetable oil food pattern differs from traditional diets in its flexible choice and preparation of food while still conforming to the basic requirements of the pattern. By the use of vegetable oils, foods low in animal fat may be made sufficiently palatable so that people ordinarily will eat them with relish. Skillful use of these oils can make the difference between a tasteless diet and a food pattern not much different from the average American food customs. While the dishes are not perfect, still they are a vast improvement over the usual suggested diets.

It should be emphasized that the food patterns discussed here reduce the serum cholesterol level but do not equally affect the other lipid constituents. It would be rash indeed to suggest that the other constituents are of no concern from the point of view of atherogenesis. Clearly it remains to be shown that food patterns such as we propose are antiatherogenic. Our efforts have been to convert diets into food patterns so that any antiatherogenic value they have may be determined on large numbers of people. As long as individual diets had to be prescribed, there was little possibility of obtaining long-term experience from larger groups concerning a relationship between lowered blood cholesterol level and atherosclerosis. While further pilot studies must be made, it would appear that some tests on larger populations may even now be undertaken.

Summary

A food pattern has been devised which makes use of ordinary foodstuff, is easy to prepare, and is acceptable to many people. This pattern reduces serum cholesterol levels in normal and in many hypercholesteremic people. In some it is more effective than the low-fat diet. The key to the food pattern has been the use of a modified unsaturated vegetable oil in combination with foods low in saturated fats.

While our goal of ready availability and complete acceptance has yet to be achieved, the food pattern holds promise of relatively easy practicability. The food pattern is sufficiently developed to suggest its use in a broader test of the theory relating blood cholesterol levels with atherogenesis. There is much yet to be learned before we can recommend the present pattern as a proper modification of the American bill of fare, which chance and choice and custom have approved.

PHYSICAL CONDITIONING PROGRAM FOR ASTHMATIC CHILDREN

Merle S. Scherr, M.D.
and
Lawrence Frankel, Charleston, W. Va.

Asthmatic children often develop a pattern of suppression of physical exercise that deprives them of initiative and confidence. In order to break this pattern a program of physical activities was developed. The experience here described involved 25 children under active treatment for bronchial asthma. A remarkably broad range of activities was found possible, from basic breathing techniques and postural exercises to swimming and self-defense. Each child was encouraged to try to improve his own record rather than to compete with the other children. For some it was the first experience with physical exercises of any kind. Parents were usually excluded from the first few sessions with each child until the child was able to master each of the techniques presented to him. With proper attention to the bronchial asthma as allergy and with the cooperation of patient, parent, physician, and physical instructor, the results obtained were beneficial to the children both in combating the disease and in improving personality adjustment.

Supervised respiratory and physical exercises have been utilized for many years as a means of improving respiration in patients who have bronchial asthma. Since 1935 the literature has contained numerous articles concerning physical methods of attempting to relieve or improve bronchial asthma.[1] Most workers have concentrated on respiratory exercises alone, with a general physical exercise program being placed in the background. When the situation of repeated suppression of physical exercise occurs in asthmatic children, a lifetime pattern may be set up which may prevent the patient from participating in physical activities even when he is free from asthma. The combination of overprotection by parents and physical incapacity due to asthma can frequently lead to the asthmatic child being deprived of all physical activities. This may result in great mental suffering and loss of much initiative and confidence which aid in his personality adjustment to life.

In November, 1956, a program was started at the Charleston, W. Va., Young Men's Christian Association (YMCA) which combined the teaching of breathing exercises with physical conditioning exercises on a level which was designed for the individual child. The first group of participants in this program consisted of six boys who were suffering from moderate to severe asthma. The program consisted of exercises which were performed in game style. Each child was taught to compete with himself and not necessarily with the group. The respiratory exercises used were those outlined by the Asthma Research Council, London.[2] In addition to these respiratory exercises, the group was taught nonrespiratory gymnastics in a program, devised by us, which would not exhaust the child. These consisted of apparatus workouts with the Roman rings, horizontal bar, and medicine ball, climbing rope, swimming, tumbling, and similar gymnastics. An attempt was made to develop confidence in these asthmatic children by teaching combatives which included the basic skills of boxing, judo, and self-defense. The progress of each child was recorded for each activity.

In May, 1957, the program was enlarged in order to allow girls to participate in the activities. Total class size was limited to 25 children between the ages of 6 and 14 years. The program meets on two afternoons each week at the YMCA, and emphasis is placed on daily home practice of the activities. A total of 28 children have been enrolled in the program since its organization. It is felt that this program will enable the teaching of respiratory and physical exercises to be placed on a local level available to all asthmatic children by utilization of the YMCA type facilities as found in most cities of the United States.

Equipment and Personnel

The physical fitness director of the Charleston YMCA was employed to carry out the actual teaching in the program under the supervision of a trained allergist. The most essential part of the entire asthma conditioning program is the instructor. He must be well qualified for teaching and must have patience in dealing with asthmatic children. Furthermore, he must be taught the basic essentials concerning allergy, and asthma in particular, in order that he may appreciate the problems involved with these children. All children have previously received permission from their physicians to participate in the program and are under active treatment for bronchial asthma.

Chief, Allergy Clinic, Charleston Memorial Hospital (Dr. Scherr), and Research Associate, YMCA Asthma Conditioning Program (Mr. Frankel).

Nylon-covered, allergen-free mats, containing foam rubber as a filler, were used for all procedures which required a horizontal position and flat surface. With the exception of these special mats, regular YMCA facilities were used. The equipment required, most of which is usually found in a YMCA, consists of mats (foam rubber, plastic covered), horizontal bars, Roman rings, knotted nylon rope (about 26 ft.), unknotted nylon rope (about 26 ft.), medicine ball, basketball and baskets, boxing and wrestling rings, boxing gloves and protection equipment, stop watch, judo jackets (homemade), class uniforms, swimming pool, and other equipment as found useful for particular groups.

A uniform was adopted which consists of a judo jacket and white rubber-soled tennis shoes, shorts, and T-shirts. The children named themselves "Bucking Bronchos" (from bucking bronchial asthma), and the T-shirts obtained were so lettered, enabling each child to be identified with the group. This was felt to be important since the individual performance in a group activity was stressed. A stop watch was necessary in order to gauge the individual child's performance. The atmosphere surrounding the program is one of play and not one of medical treatment. The fact must be stressed if the child's interest is to be kept active. Music is utilized in performing many of the exercises. We have found that this creates more interest and lessens fatigue than if the exercises are performed as a "gym" activity.

Specific Methods

The program is divided into the following four broad phases: basic breathing techniques, postural exercises, gymnastics, and adaptation conditioning or confidence building activities (combatives).

Basic Breathing Techniques.—All basic breathing techniques are performed competitively in that the child competes with his own ability and not with the ability of his neighbor. Emphasis is placed on diaphragmatic breathing, costal breathing, and asymmetrical breathing. The general plan follows that which is recommended and outlined by the Asthma Research Council, London. Basic breathing exercises are to be done daily and when a patient feels the onset of an attack of asthma.

Abdominal or Stomach Breathing: While performing abdominal or stomach breathing exercises, the child lies on his back, with knees bent, feet on a bed or chair, arms to the side, and completely relaxed. One hand is then placed on the abdomen. He breathes out slowly through the mouth, making an "F" or "S" sound and making the hand sink into the abdomen. He breathes air in quietly through the nose, as abdominal muscles become relaxed and the hand comes up. Exhalation is timed with a stop watch, and weekly improvement is recorded as a gauge of progress. The upper part of the chest does not move. Expiration is long and inspiration is short. Exercises are done three times a day, 10 minutes at a time at first. Plenty of fresh air is desirable.

Diaphragmatic Assistance Breathing: In diaphragmatic assistance breathing the child lies on his back, with head and shoulders resting on a pillow, hands placed on lower ribs (thumb and fingers together), and knees bent. Shoulders are kept down and relaxed. The exercise consists of breathing out slowly through the mouth with the "S" sound, with a final squeeze at the end of this breath with the palms of the hands to insure emptying the lungs as much as possible.

Abdominal Muscle Exercise: In performing abdominal muscle exercises the child lies on his back, with knees bent, and feet on a bed or chair. Arms and shoulders are relaxed. The right knee is slowly brought to the chest while the child is breathing out, by tightening abdominal muscles. When he is ready to breathe in, he lowers the knee. The exercise is repeated with the left knee and with both knees together. Then, with the hands clasped behind his neck, the child sits up, brings the right elbow outside the left knee and then the left elbow outside the right knee (with feet held down in beginning). In performing the V-sit exercises the child sits on floor, with legs apart, and raises both feet 12 to 14 in. from the ground for 30 seconds, in good form.

Abdominal Breathing: In performing abdominal (or diaphragmatic) breathing exercises, the child sits in a chair with his back supported against the chair, completely relaxed. The hands are on the lower ribs and the child slowly breathes out with the "S" sound, tightening the abdominal muscles by making the abdomen go in, and pressing the last of the air out of the lungs as in diaphragmatic assistance breathing. The abdomen is relaxed as the child breathes in through the nose. (Note: The upper part of the chest should not be raised at any time.)

Forward Bending Exercise from Sitting Position: In doing the forward bending exercise the child sits with feet apart and arms relaxed at his side. He breathes out slowly with an "S" sound as he bends forward, first the head, then the shoulders, until the head is almost to the knees. Gradually he raises his head and straightens his back until the lower part of the back reaches the chair. (This is done on the "S" breath.) He breathes in as the middle part of the back, shoulders, neck, and head are straightened. In a sitting position, he breathes out quickly and then breathes in a short breath.

Forward Bending Exercise from Erect Position: In the forward bending exercise the arms are overhead, thumbs locked and arms in line with the ears. The abdominal and gluteal muscles are retracted, and the child bends in eight staccato counts until the fingertips touch the floor. He then returns to the starting position in eight staccato counts, with muscles contracted.

Postural Exercises.—Postural exercises are to be done between breathing exercises.

Elbow Circling Exercise: The elbow circling exercise is done while the child is sitting in a chair, leaning forward from the waist, keeping the back straight. Fingertips are rested on the shoulders; the elbow is bent and placed out to the side in line with the shoulders. The elbows are circled forward, up and back, and down. Four or five circles are made, and then the child relaxes.

Windmill Exercise: In doing the windmill exercise the child stands with feet slightly apart and arms to the side, halfway between the shoulders and hips. The arms are crossed in front. They are then raised, crossed in front of the face, and moved up over the head. Next they are spread apart and dropped to the side and to the starting position. *This is repeated 10 or 12 times, and then the child* rests.

Gymnastics.—Gymnastics are performed under supervision at all times. For rope climbing, two ropes are provided. One is knotted every 8 in., and the other is unknotted. The child is started on the 26-ft. knotted rope, and a rapid transition is made to the unknotted rope. This builds confidence and is usually accomplished in less than three weeks.

Tumbling and exercises with the horizontal bar and flying Roman rings are performed by the entire group on an individual basis. Calisthenic drill is performed by the group to a lively musical tempo. It has been found that phonograph music has increased interest and tolerance in the entire group and appears to lessen fatigue. We have made music an essential part of our basic program.

Medicine ball and basketball have been found to have an important place in the program, particularly since they are played in the usual school gymnasium. They aid in coordination and group adjustment. Swimming has become a part of the program, since it combines the use of all muscle groups with practical breathing functions.

Adaptation Conditioning, or Confidence Building Activities: Combatives.—Adaptation conditioning or confidence building activities enable the child to adapt to daily living. This course is grouped under the term combatives and is adapted only to the children in the group with kinesiological skills. Use of strength in a bullying manner is neither encouraged nor permitted. The principles are a composite of judo, wrestling, boxing, and La Savate. The children are taught graceful movement, proper body mechanics, and rapidity of action as the prime factors. All of these prime factors lead to the conservation of energy, which is an obvious necessity for the group of asthmatic children.

In lesson 1 of this course there is discussion and demonstration of balance and leverage, including breaking of grasps and holds, offensive and defensive postures, disturbing an opponent's balance in frontal and lateral planes, and take-downs from the erect position.

In lesson 2 are taught tricks of leverage using only hands and wrists, tricks from handshake, simple use of hammerlock, and use of breakfalls and roll outs (not formalized tumbling) in learning to fall without injury.

Lesson 3 concerns usage of elbows, knees, forearms, and ulnar border of hand for offense and defense. Included in this are releases from front and rear, such as front bearhug, choke from front, front hug (arms locked), strangle hold from rear, and body grasp from rear.

Lesson 4 concerns the technique of throwing, including the regular version of the hip throw, the sweeping hip throw, cross hock, and shoulder throw. Parries, including the outside parry, inside parry, cross parry, and scissors block, are taught at this lesson.

Lesson 5 concerns the use of the jacket in strangle defense, including the cross-arm technique, reaching carotid arteries, jolt choke, and hammerlock to forehead strangle.

Lesson 6 concerns simple nerve center defense applications.

Lesson 7 concerns foot techniques such as foot jab, knee and ankle trips, knee lift and knee drop, and other trips and counters.

The above procedures are demonstrated to the children and taught with the understanding that they are to be used for defense only. It is not the purpose of this class to produce "bullies" but rather to allow these children to learn basic techniques of defense against aggression. In addition to the above program, the children are taught a multiplicity of simple wrestling and boxing techniques which are adapted to the individual child's orientation to previous lesson plans. Each child is taught as an individual, and his circumstances are adapted to the lesson plans.

Results

The results of this preliminary report have not been subjected to statistical evaluation. All children but three in the program have been able to adjust well to a group activity which has been kept at the individual child's level. These three were replaced in the group in order to keep the enrollment at 25 children. Competition has been encouraged with the child's own record rather than the records of the other children. All of the children were able to participate in every activity. For many of the children in the program, this was the first experience with physical exercises of any kind. For some, it was the first really successful attempt at participation in group activities without dropping out because of their inability to participate due to bronchial asthma.

A successful attempt was made to utilize breathing exercises in an attempt to throw off the asthmatic attack in conjunction with medication. This made the child feel that he himself was actually aiding his own therapy instead of waiting for someone else to administer medicaments. In no case was the child made to feel that physical and respiratory exercises were the solution to his bronchial asthma problem. Emphasis was placed on his allergy management and the importance of his cooperation with his physician, parent, and physical program director. The idea of the child belonging to a "team" of physician, parent, physical program director, and patient created a greater desire for cooperation, since his results in the program were directly proportional to his cooperation as part of the team.

The three "failures" were all boys. One was deemed an intractable asthmatic and is now a patient in the Jewish National Home for Asthmatic Children, Denver. The other two were withdrawn by their parents, who resented the implications that their children had personality adjustment problems because of their environmental situation and disease. The other children in the group have demonstrated improvement as a result of participation in the asthma conditioning program by means of improvement and increase in school, home, and church activities, as well as a loss of fear concerning their asthmatic attacks. The frequency and severity of asthmatic attacks have been decreased in these patients as a group, and none of the children has required hospitalization for bronchial asthma since joining the group. In the year prior to joining the group, almost one half of the children had been hospitalized for moderate or severe bronchial asthma. Pulmonary function studies also revealed improvement. We will not attempt to enter into a full discussion of the many involved factors but will state that we feel this improvement is due primarily to enlightenment of the child and parents concerning bronchial asthma which resulted in better cooperation with the physician and treatment.

In addition, the improvement in the general physical condition of each child aided him to better cope with his disease. There was a definite emotional improvement in each child as demonstrated by his better adjustment to others in his daily activities. Many children were able to participate in such activities as summer camping, hikes, and school sports activities. One boy has become a star player on the champion "Little League" baseball team in Charleston. Prior to his enrollment in the asthma conditioning program, he was little interested in the sport. Other children have taken jobs as newsboys and as delivery boys, activities they would not previously have attempted because of lack of confidence in themselves. Others have gained the respect of their friends and classmates by no longer being the coward or weakling of the group. There are few "bullies" who will "pick on" a child who has a knowledge of judo, boxing, and wrestling, regardless of the child's handicap of active bronchial asthma. Each child in the group looks forward to the sessions of the asthma conditioning program with great eagerness. In addition, an achievement gold medal award is given at an annual party to each child for improvement over his own previous performance. This tends to give the child another incentive toward a goal of good health.

A familiar example of an asthmatic child is that of Theodore Roosevelt. The following quotation from a recent publication [3] reminds us that he, too, made use of a physical reconditioning program.

> But Theodore, as he grew older, was nontheless a boy sorely beset. "I was a sickly, delicate boy," he wrote, "and suffered much from asthma. One of my memories is . . . of sitting up in bed gasping, with my father and mother trying to help me." His arm muscles were so weak that he could not stand up to other youngsters. One day his father encouraged him: "You have the mind but not the body. . . . You must make your body. It is hard drudgery, but I know you will do it." Theodore organized a gymnasium with horizontal bars and a punching bag on the second floor of the town house and set about to do just that.

Comment

It is greatly appreciated that one of the most important results of asthma is the mental suffering and loss of initiative and confidence arising from the physical handicap. This is often a serious problem in the normal development of children. An asthmatic child may miss school and is frequently deprived of taking part in group activities with his schoolmates. Because of this and other factors, such as overprotection at home, he may suffer behavior and personality disorders. He may become unmanageable, irritable, and possibly dependent, or he may go to the other extreme and become aggressive, hostile, demanding, and bullying toward his parents and other children. He feels that he must compete with nonasthmatic children, and when he cannot successfully do this he becomes more of a problem in management. This YMCA program attempts to teach the patient to compete against himself rather than his nonasthmatic playmates. Each child who entered the program did so with a large amount of hostility and fear until it was demonstrated that he would have to compete only against himself.

Parents were excluded from the first few sessions with each child until the child was able to master each of the techniques presented to him. Only at this time were the parents allowed to attend the classes. This was done because it was demonstrated early in the program that the presence of the parents would distract the child from performing to the best of his ability. This decision was made after observation during the early sessions that the negative nodding of the parent's head or a cross look at the child would completely demoralize him and actually prevent him from even attempting to perform the activities. This is a partial, temporary form of the practice of "parentectomy" as advocated by the Jewish National Home for Asthmatic Children, Denver.[4]

Summary

A practical physical conditioning program for asthmatic children has been presented which may be adapted in any city with YMCA or equivalent facilities and a qualified physical instructor who is willing to learn the basic essentials concerning bronchial asthma. The program combines respiratory exercises, general physical exercises, and confidence building activities which aid the asthmatic child in combating his disease as well as improving his personality adjustment to individual and group activities and life in general. Emphasis is placed on cooperation between patient, parent, physician, and physical instructor as a team. Proper allergy management of bronchial asthma combined with a proper physical program designed for the individual child has given successful results in 25 asthmatic children.

803 Atlas Bldg. (Dr. Scherr).

The authors wish to express their appreciation to Mr. Myron Lewis, executive director, Mr. L. Warren Johnson, physical education director, and Mrs. Marjorie Tully of the Charleston YMCA and Miss Zelma Staats whose cooperation made this project possible.

This program has been supported in part by grants from Warner-Chilcott Laboratories, Division of Warner-Lambert Pharmaceutical Co., Morris Plains, N. J., and Center Laboratories, Port Washington, N. Y.

PERINEAL URETHRAL DIVERTICULUM—COMPLICATION OF REMOVAL OF ISCHIUM

A. Estin Comarr, M.D.
and
Ernest Bors, M.D., Long Beach, Calif.

Ischial decubitus ulcer is rather common among patients with spinal cord injuries, and it has been treated by the generally accepted method of removal of the ischium. This operation has been complicated by the development of a perineal urethral diverticulum, first observed and reported in four patients in 1955.[1] Since then, the number of cases has increased so much that it appears justified to emphasize this complication to the urologist, the plastic surgeon, and the general practitioner, who eventually take care of the patient once his specialized treatment at a spinal cord injury center is completed.

Removal of the ischium is the generally accepted method of treating ischial decubitus ulcer in patients with spinal cord injuries. Perineal urethral diverticulum has been observed in 22 of 48 patients after removal of the ischium (46%). It results from interference with the suspension of the triangular ligament and removal of the ischial tuberosities, thus exposing the pars diaphragmatica and the pars nuda urethrae to pressure. The diagnosis is made clinically (ischial sinus, perineal swelling, or ulcer), urethrocystographically, and urethroscopically. In the majority of cases treatment consists of introducing an indwelling catheter and of improving the general condition of the patient.

From the Spinal Cord Injury Service, Veterans Administration Hospital, Long Beach, and the Department of Surgery (Urology) of the School of Medicine of the College of Medical Evangelists and the University of California at Los Angeles.

Read before the Section on Urology at the 107th Annual Meeting of the American Medical Association, San Francisco, June 24, 1958.

Read in part by Dr. Comarr before the third annual Clinical Paraplegia Conference of the Veterans Administration, West Roxbury, Mass., 1954.

Methods, Material, and Results

Impressed by the severity of our first case, we now use urethrocystography routinely at regularly spaced intervals after every removal of the ischium. A maximum of 150 cc. of 10% methiodal (Skiodan) sodium solution is permitted to fill urethra and bladder by the gravity method; the penis is occluded and kept fixed to one side by the Cunningham clamp-skin clip-sandbag method [2]; anteroposterior exposures and right obliques are then taken. For urethroscopy we use a no. 24 panendoscope introduced under vision.

Two hundred nineteen patients with traumatic spinal cord lesions were examined at random, irrespective of the level and completeness of or the time-interval since injury. We found 171 patients for whom removal of the ischium had not been done who had no perineal diverticula. Of the 48 patients who had had this operation, 22 (45.8%) had diverticula; of 12 patients with unilateral removal of the ischium, 1 (8%) had a diverticulum, while of 36 patients with bilateral removal of the ischium, 21 (58%) showed diverticula of varying size and shape. The patient with diverticulum after unilateral removal of the ischium had an upper motor neuron lesion (spastic paralysis).

Eighteen of the 21 patients with diverticulum after bilateral removal of the ischium had lower motor neuron lesions (flaccid paralysis), 1 patient had an upper motor neuron lesion, and 2 had a combination of upper and lower motor neuron lesion with regard to the pelvic floor musculature. Of the 18 patients with lower motor neuron lesions, 14 had flaccid paralysis as a result of the injury, and 4 patients with originally spastic paralysis had flaccid paralysis after a subarachnoid alcohol injection (three cases) or an anterior rhizotomy (one case). The diverticulum in the patient with unilateral removal of the ischium was detected 5 months after operation, while the diverticula in the 21 patients with bilateral operation were found from 8 months to 11 years after the intervention.

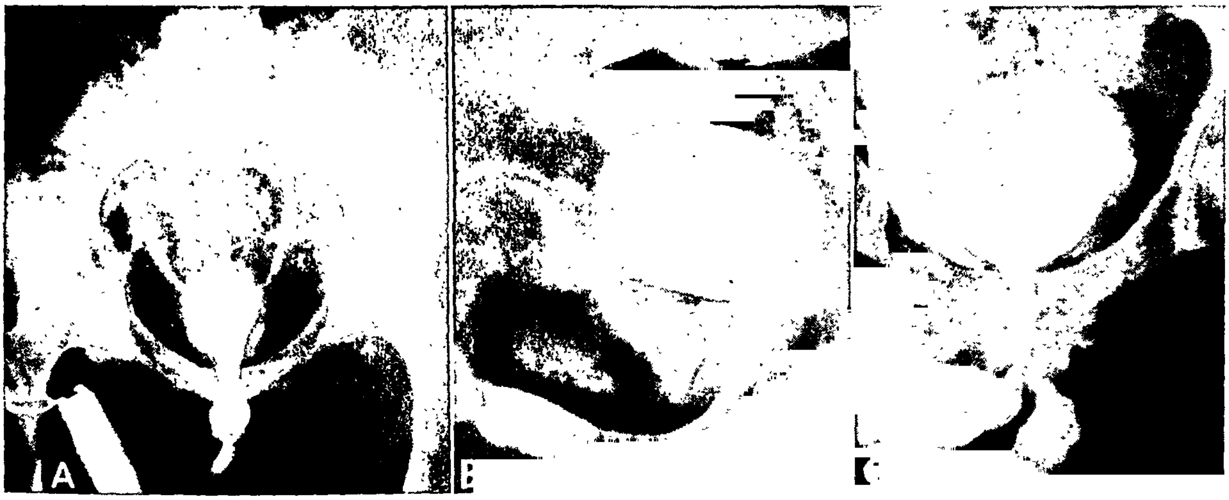

Fig. 1.—Segmentally complete lesions: *A*, at T-7 with spastic paralysis (bilateral removal of ischium). Note bilateral vesicoureteral reflux, bilateral prostatograms, and contracted bladder. Open vesical neck and symmetrically dilated diaphragmatic part, and possibly a relaxed pars nuda, cause solid uninterrupted outline of posterior and anterior urethra. Two small appendixes represent possible Cowper's glands. *B*, at T-8 with spastic paralysis (left unilateral removal if ischium). Oblique view simulates defect of right ischium due to overlying superior pubic ramus. Note penoscrotal diverticulum in addition to perineal diverticulum which includes diaphragmatic part and pars nuda. *C*, at T-11 with flaccid paralysis (bilateral one-stage removal of ischium). Note rectangular appearing deformity at level of pars diaphragmatica and secondary parasagittal diverticulum resulting from abscess (on the left). Pars prostatica outlined because of open vesical neck.

Comment

Urethrocystography as a routine method is preferable to simple urethrography in all patients with spinal cord injury generally, and in these patients particularly, for two reasons: 1. It is possible to detect other not-infrequent complications of the penoscrotal urethra, of the bladder wall, and of the vesicoureteral junction, e. g., reflux (fig. 1*A*). 2. It is an economical procedure which saves both financial expense and repeated exposure to radiation.

The pathogenesis becomes understandable if one considers the anatomy and roentgenologic anatomy of the perineal urethra, and the changes of tissue suspension and weight-bearing caused by surgery. The urethra can be differentiated roentgenologically and anatomically into four parts: a prostatic part, a diaphragmatic part (or membranaceous or fixed), a pars nuda, and an anterior mobile part.[3] Of interest here are the pars diaphragmatica and pars nuda. The former belongs to the posterior urethra; the latter, bordering directly on the pars diaphragmatica, is the hindmost part of the anterior mobile urethra; it is unprotected by muscles and, therefore, vulnerable to internal instrumentation as well as to external trauma. Its only protection in the sitting position is the hollow which is formed by the outjutting ischial tuberosities. The diaphragmatic urethra is originally well protected by the triangular ligament, which is composed of the l. transversum pelvis and l. arcuatum and represents the membranaceous part of the muscular pelvic diaphragm; it is suspended between the inferior pubic rami and is not dissimilar to an interosseous membrane.[4] By radical removal of the entire tuberosity of the ischium and trimming down to the utmost the inferior pubic ramus,[5] as is done in subperiosteal removal of the ischium, both mechanisms are severely disturbed; the protection of the pars nuda and the suspension of the diaphragmatic urethra.

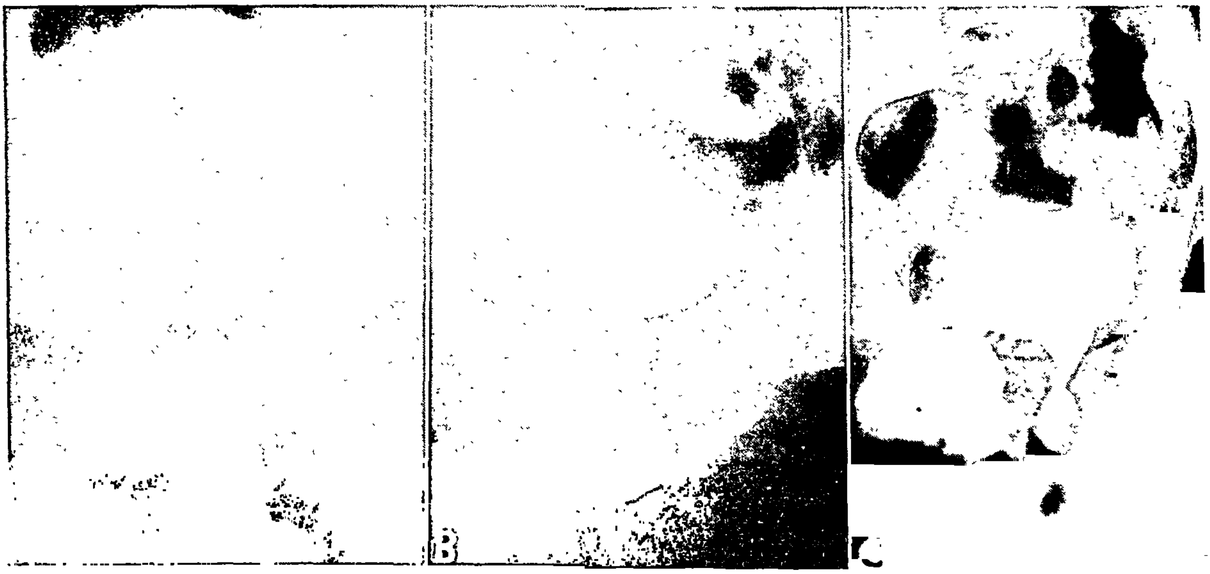

Fig. 2.—Segmentally complete lesions: *A*, at T-10 with flaccid paralysis (bilateral removal of ischium). Note large size of diverticulum extending to right and left and involving diaphragmatic and bulbous urethra in spite of closed vesical neck. *B*, at T-11 with flaccid paralysis (bilateral removal of ischium). Note left prostatogram in addition to perineal diverticulum, including pars diaphragmatica and pars nuda of urethra. Pars prostatica is outlined because of open vesical neck. Diverticulum includes proximal part of anterior urethra. *C*, at T-10 with flaccid paralysis (bilateral removal of ischium). Resection of diverticulum occupying space of ischial bone. Small neck connects sac with dilated, spindle-shaped, diaphragmatic urethra, demarcated by the M. compressor urethrae nudae (3) from anterior urethra. Urinary drainage from sinus in scar. Open vesical neck causes outline of prostatic urethra.

Thus this entire part is exposed to pressure and, therefore, to mucosal damage with all its consequences of periurethral extravasation, abscess, fistula, or diverticulum formation. The latter may extend laterally, ensconcing the bone stump of the resected inferior pubic ramus with subsequent osteitis and osteomyelitis; or it may develop parasagitally and anteriorly along the perineal raphe. Diversion of the urinary stream by suprapubic cystostomy, instituted immediately after injury, is no guarantee against the development of this complication. We have observed a median perineal ulcer corresponding to the site of the pars nuda urethrae in one patient of this series who had a permanent suprapubic cystostomy ever since injury and developed the ulcer many years after bilateral removal of the ischium.

The diagnosis is made clinically, roentgenologically, and urethroscopically. Clinically, there may be a sinus in the scar of the previous operative site with urinary or purulent drainage, as observed in our first two cases [1]; there may be a simple median perineal decubitus ulcer; or there may be a perineal, intermittently appearing swelling with escape of urine or hemorrhagic pus from the external urethral meatus on pressure. Roentgenographically, a wide, often bizarre variety of lesions is seen (fig. 1*B* and 2), which range from an apparently insignificant dilatation of the pars nuda and diaphragmatica of the urethra to huge unilateral or bilateral sacculations. Urethroscopically, again a variety of findings is present—from a small spindle-like dilatation to a diverticulum the neck of which may be wide enough to admit a no. 24 panendoscope. In advanced cases the remainders of the inferior pubic ramus can be seen to protrude as a whitish cottonlike mass. The differential diagnosis from other pathological changes of the urethra at the penoscrotal junction poses no problem.

In the last analysis, perineal diverticulum results from decubitus ulcer which, caused chiefly by neglect, is not infrequently multiple. Multiple ulcers are the main cause of amyloidosis.[6] Therefore, a Congo red test should be performed in all cases of diverticula with either endoscopically visible bone protrusion or a history of multiple decubitus ulcers.

BIOLOGICAL FALSE-POSITIVE RESULTS IN SEROLOGIC TESTS FOR SYPHILIS

FINDINGS IN A LOW SOCIOECONOMIC POPULATION GROUP

George W. Waring Jr., M. D., Alfred S. Lanes, M.D.
and
Herbert Mescon, M.D., Boston

Seventy-five patients with repeatedly positive standard serologic reactions for syphilis were given the Treponema pallidum immobilization (TPI) test. No included person had a history or physical findings suggesting infection, and no patients referred as having contact with syphilis or discovered to have an infected consort were accepted. Twenty-three of the series were Caucasian and varied widely in socioeconomic background. In 39% of these the results of the TPI test were negative and were classified as probable false-positive reactions. Fifty-two of the patients were Negroid and thought to be a relatively homogeneous social and economic group. All had positive reactions to the TPI test. This striking difference is consistent with the accepted epidemiology of syphilis. The authors emphasize the importance of the background and habits of patients in interpretation of the results of serologic tests for syphilis.

The 50th anniversary of the discovery of the Wassermann reaction was celebrated in 1956 with a restraint imposed by some uncertainty as to its reliability. Reservations about this procedure and its modifications are not new, for they were long ago classified as reagin tests. The term reagin indicates a seroreactive substance which may or may not be a true antibody, and the Wassermann reaction received this nondescript, poor-relation status years ago. Nevertheless, the test quickly proved its clinical usefulness and, somewhat paradoxically, acquired diagnostic authority nearly absolute in degree. For practical purposes, Wassermann reactivity has been viewed as synonymous with syphilitic infection. Physicians nevertheless have regularly encountered patients with persistently positive findings on reagin tests in whom syphilis seemed to some degree improbable, and the idea that some of these reactions are falsely positive gained gradual acceptance.

This concept, however, rested wholly on clinical opinion until the investigations of Nelson and Mayer,[1] which revealed in syphilitic serum an antibody independent of Wassermann-reactive substance. This has been made the basis of a diagnostic procedure called the Treponema pallidum immobilization (TPI) test, which has great value as a verification technique. More recently, complement-fixation reactions have been devised with use of extracts of treponemes, and they too detect antibody other than reagin.[2] Results of the treponemal tests are positive in a high percentage of patients with syphilis after the second or third month and rarely, if ever, show positive reactions in healthy persons free of any suspicion of infection. The specificity of these reactions is high, but the tests are technically difficult to perform and for a number of reasons will not detect 100% of cases of syphilis. This limitation is clearly demonstrated in a recent report[3] from a laboratory of excellent standards where the results of each test were negative in about 5% of serum samples positive to the other.

In 1952, Moore and Mohr[4] reported on 300 Caucasian patients, all of good economic status, from their private consulting practice. None of these had any evidence of syphilis except persistently positive standard tests. Forty-three per cent had negative findings on the TPI test and were regarded as false-positive reactors. This estimate has been affirmed by numerous others,[5] though the socio-epidemiologic background of the patients in later studies has been less clearly defined. At all events, the reliability of conventional serodiagnosis of syphilis has been vigorously challenged. The resulting enthusiasm for the diagnosis of the false-positive reaction has been certainly great—and probably excessive. Witness that, of 1,407 serums from patients with this diagnosis, submitted by physicians across the United States, 45% were found to be positive on treponemal tests.[3]

Since little published information has appeared dealing with the problem in social and racial elements in which syphilis is especially prevalent, a small-scale study of the question has been undertaken in the Genito-Infectious Disease Clinic of the Massachusetts Memorial Hospitals and the department of dermatology of the Boston University School of Medicine.

From the departments of dermatology and internal medicine, Boston University School of Medicine, and the Genito-Infectious Disease Clinic of the Massachusetts Memorial Hospitals.

Read before the Section on Dermatology at the 107th Annual Meeting of the American Medical Association, San Francisco, June 26, 1958.

Materials and Methods

In general, the Caucasian patients studied were those in whom the clinic physicians have felt the need for diagnostic verification. The Negro patients, on the other hand, were unselected.

Referrals to the clinic were largely from the epidemiologists of the Department of Public Health and from the ward and outpatient services of our own and a large municipal hospital. Documented reagin reactivity for at least three months was required for inclusion in the study. No patients referred as having contact with syphilis or discovered to have an infected consort were accepted. However, numerous cases or contacts of gonorrhea are included.

No included person had a history or physical findings suggestive of infection. The majority had spinal fluid examinations; findings in these were normal except in two persons, who had a slight protein level elevation.

Sixty-nine per cent of the group were Negro. Of incidental interest are the facts that 35% were at one time partners of broken marriages and several referrals were from correctional or penal agencies.

No effort was made to exclude patients with other chronic disease. One patient each with lupus erythematosus, sarcoid, hemochromatosis, gout, diabetes, and recently active tuberculosis was included in the series, and all had seemed to have syphilis except the patient with lupus erythematosus.

The study group comprises all but seven of those subjected to the TPI test. These were dropped chiefly because of inadequate serologic study to qualify as having real problems or because convincing clinical evidence of infection was discovered during observation.

Results

Immobilization tests have been obtained for us by Venereal Disease Division, Massachusetts Department of Public Health. Of the total series of 75 patients, 9 (12%) had negative findings. All of these probably false-positive reactions were in the Caucasian group, the selection of which has already been discussed. All of the 52 Negro patients had positive reactions.

Acknowledging the statistical limitations of this small study, it appears reasonable to suggest that the false-positive phenomenon occurs about one-fourth as often in the socioeconomic group which attends our clinic as in patients of more fortunate background and that it is quite rare in the Negro race.

Comment

Assuming that our Negro patients are persons of wide-ranging sexual activity within a group seeded with infection, this study becomes simply a demonstration of the epidemiology of syphilis, and as such it is presented. It underscores the importance of this kind of information in clinical diagnosis. Examination of the sexual partner(s) of a patient, as well as his children and often his parents, is a vital part of the diagnostic (and the public health) investigation. It is also important for the physician to develop an estimate of the patient's sexual habits. Pursued with tact and kindness, this matter is not always as futile as is sometimes supposed. To this circumstantial evidence should be added the spinal fluid findings and review of the patient's general medical status in search of clues to chronic disease known to cause false-positive reactions. It is well to include conventional hematological and urine studies and, perhaps, albumin and globulin measurement in the blood. Treponemal tests can then be interpreted against this background. It is easy to visualize situations in which results should be ignored if negative and are therefore superfluous. If positive, they are probably definitive.

Conclusions

The limitations of reagin tests are fully acknowledged. Fallibility of the treponemal tests, of a lesser order of magnitude, must be recognized. In our own study, by using epidemiologic preselection, we have assembled a group in which the margin of error of the reagin tests approaches zero, and we suggest that published rates approaching 50% result largely from the same factors applied in reverse. Our data are also a reminder of the importance of epidemiologic considerations in the diagnosis of syphilis. Finally, the clinician must collect and evaluate a variety of information, accepting the fact that not all problems and uncertainties can be resolved in the laboratory.

CLINICAL NOTES

COARCTATION REPAIR WITH RELIEF OF HYPERTENSION

REPORT OF A CASE IN A FIFTY-SEVEN-YEAR-OLD MAN

C. Frederick Kittle, M.D., James E. Crockett, M.D.
and
E. Grey Dimond, M.D., Kansas City, Kan.

Individually there is nothing unique about the age of 57 years, incapacitating hypertension, or coarctation of the aorta. However, the association of these three and relief of the latter two by a surgical procedure at an age when operation is not usually advised is sufficiently provocative to warrant detailed consideration.

Report of a Case

A 57-year-old man had been observed at the University of Kansas Medical Center since 1954, at which time he had been given a diagnosis of coarctation of the aorta. He had known of his hypertension since the age of 18 years. His complaints were of exertional dyspnea, fatigue, headaches, and vertigo and had been particularly severe since 1951. Angina occurred with exertion. In 1955, he had an episode of sudden headache, nausea, dizziness, and slurred speech which was diagnosed as a cerebral thrombosis. Coldness and exertional claudication of his legs had been present for many years.

For the three months prior to his admission in 1957, headaches and vertigo occurred daily to such an extent that he was forced to discontinue work and remain at bed rest. Inquiry revealed that he had had mumps at the age of 16 years with a secondary orchitis. He was married and had one daughter.

Physical examination showed a ruddy-faced adult with smooth features, a eunuchoid body, finely textured skin, and bilateral gynecomastia (fig. 1). Arm blood pressures were 190-210 mm. Hg systolic and 80-90 mm. Hg diastolic. Blood pressures could not be determined in the legs by auscultation. Examination of the eyegrounds showed an increased tortuosity of the retinal vessels with moderate arteriovenous compression. No hemorrhages, exudates, or papilledema were noted. Prominent pulsations were noted in the carotid and subclavian arteries, and collateral circulation could be palpated over the upper part of the chest. At the aortic area there was a grade 3 harsh systolic murmur with accentuation of the second aortic sound. There was a normal sinus rhythm. A systolic murmur could be heard over the interscapular area of the chest wall. The femoral artery pulsations were barely palpable, while the dorsal pedal and posterior tibial pulses could not be felt. The testes and external genitalia were smaller than usual, although the body hair was normal in distribution.

An electrocardiogram showed left ventricular hypertrophy and ischemia. Chest roentgenograms revealed an enlarged heart, particularly the left ventricle, and notching of the inferior surfaces of the third to eighth ribs bilaterally. The aortic knob was diminished. The 24-hour 17-ketosteroid excretion on two occasions was 7.2 mg. and 13.6 mg. (normal range 10-20 mg.).

In view of the patient's severe and increasing disability, operation was advised and done on Oct. 4, 1957. Endotracheally administered nitrous oxide-oxygen was used for anesthesia. Abundant collateral circulation was encountered in the chest wall, particularly in the subcutaneous and intermuscular areas. An "adult" type of coarctation was present distal to the left subclavian artery with marked poststenotic dilatation of the descending aorta. The aortic arch measured 22 mm. in diameter, the left subclavian 16 mm., and the dilated descending aorta 37 mm. An atherosclerotic plaque was noted along the medial side of the aorta proximal to the coarctation. In general, the aorta was quite elastic and supple in consideration of the patient's age. After mobilization of the vessels in this area, a segment of aorta 2 cm. long was excised. The internal orifice at the coarctation was 2 by 3 mm. (fig. 2). Direct end-to-end anastomosis could then be accomplished with use of a 0000 silk suture. An anastomosis measured at 25 mm. in diameter was obtained. During dissection about the coarctation and until the anastomosis was completed, trimethaphan (Arfonad) camphorsulfonate was administered intravenously to maintain a hypotension of approximately 60-90 mm. Hg systolic.

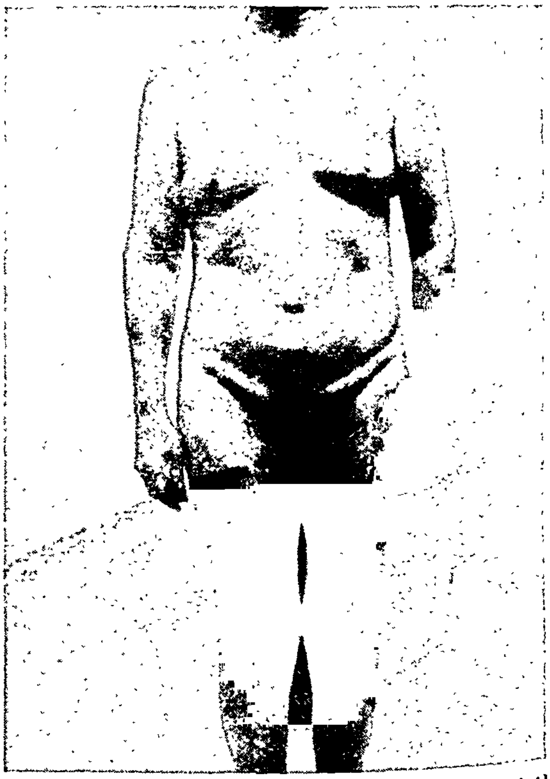

Fig. 1.—Patient with bilateral gynecomastia and eunuchoid stature.

Postoperatively, the blood pressure was normal; it has remained at normal levels subsequently, varying in a range of 120-150 mm. Hg systolic and 70-80 mm. Hg diastolic. A chest film taken two weeks postoperatively showed a marked decrease in heart size, and later films revealed a normal size and contour (fig. 3).

From the departments of surgery and medicine, University of Kansas Medical Center.

When seen two and again six months postoperatively, the patient stated that, since operation, no headaches or vertigo had occurred. Other cardiovascular symptoms were not present. Blood pressures in the arm were 140/80 and in the leg 190/110 mm. Hg.

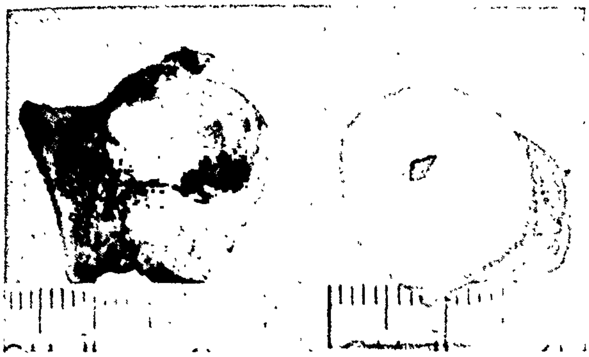

Fig. 2.—Resected segment of aorta containing coarctation.

Comment

Since the operative correction of coarctation was first accomplished in 1945,[1] many discussions regarding indications for treatment, and particularly regarding the age limits for this procedure, have occurred.[2] O'Sullivan and Glenn,[3] in discussing contraindications to the repair of coarctation, stated: "We have set no upper age limit for operation, but certainly a person in his forties presents an increased risk, a more difficult operation and a lesser likelihood of reversion to normality."

In consideration of this subject, the operative technical difficulties, as well as irreversibility of the hypertension in the older patient with coarctation, have been stressed. Thus, O'Sullivan and Glenn[3] mentioned a woman, aged 40, who underwent a successful operative procedure but whose hypertension persisted. Adequacy of the anastomosis was demonstrated by angiography. Clagett and Jampolis[4] told of exploration in a 50-year-old woman with coarctation in whom resection could not be completed for technical reasons. Similarly, Gross[5] described a 50-year-old patient whose coarctation was repaired with relief of hypertension but who postoperatively showed signs of spinal cord damage. Herron and co-workers[6] reported on a 49-year-old man with coarctation of the aorta and partial, probably secondary, Brown-Séquard syndrome. Operative correction of the coarctation in this patient was followed by relief of the hypertension.

The question of operability in the older age group is also compounded by such degenerative changes near the coarctated aortic segment as aneurysm formation and atheromatous and arteriosclerotic plaques. These constituted an important consideration to anastomosis prior to the availability of acceptable vascular prostheses. Since the introduction of satisfactory prostheses, the restoration of aortic continuity should no longer pose as prominent a problem technically.

The use of hypotensive anesthesia for brief operative periods has proved to be an important technical adjuvant for great vessel procedures, facilitating the mobilization of vessels near the coarctation as well as the actual anastomosis.[7]

The significance of this patient's eunuchoid appearance deserves comment and may explain, to some extent, the lack of degenerative changes in his vascular system. There have been suggestions that eunuchs do not develop arteriosclerosis as early to the same extent as individuals with normal androgenic function. However, this is still controversial,[8] and proof of decreased androgen in our particular patient, apart from his appearance, is lacking.

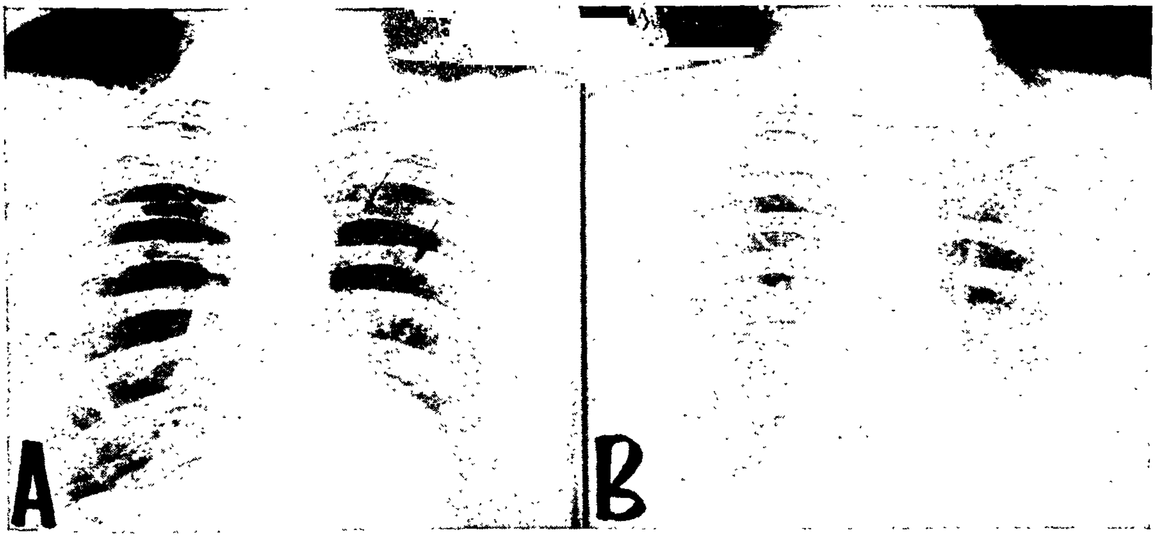

Fig. 3.—Roentgenogram of chest showing, *A*, preoperative cardiomegaly and rib notching (*arrows*) and *B*, postoperative diminution in heart size.

It is of particular interest in this patient to note that his hypertension, although present for 39 years preoperatively, was not fixed and irreversible but did revert to normal after excision of the coarctation and establishment of a satisfactory aortic lumen. As yet, no test has been devised to determine which patients will have unresponsive hypertension after coarctation repair, and the burden of proof must be with those who advise against operation in the presence of this anomaly.

Summary

A 57-year-old man with known hypertension for 39 years due to coarctation of the aorta was incapacitated by daily headaches, vertigo, angina, and dyspnea. Operative correction of the coarctation was done with prompt subsidence of his blood pressure to normotensive levels and complete relief of his symptoms.

Age, per se, should not be a contraindication to the operative correction of coarctation when symptoms are present. The availability of satisfactory vascular prostheses and use of hypotensive anesthesia are valuable adjuvants to facilitate management of the technical problems encountered with this anomaly.

USE OF CITRATED CALCIUM CARBIMIDE IN ALCOHOLISM

Earl H. Mitchell, M.D., Washington, D. C.

Effective control of alcoholism by chemotherapy dates from 1943, when Asmussen and co-workers[1] and Jacobsen and Martensen-Larsen[2] first described the reaction of patients receiving disulfiram and alcohol. In 1951, Graham[3] demonstrated that disulfiram interferes with the metabolism of alcohol by inhibiting it at the acetaldehyde stage. Physical symptoms of the alcohol-disulfiram reaction (flushing, headache, tachycardia, and dyspnea) are believed to be due to the accumulation of acetaldehyde, and these symptoms are sufficiently unpleasant to serve as deterrents to further drinking. The value of disulfiram has been generally recognized, but its application has been limited by certain unpleasant side-effects, the most common of which are gastrointestinal disturbance, impaired taste, unpleasant breath and perspiration odors, lassitude, drowsiness, and diminished sexual potency.

In 1953, Fergusen[4] reported that citrated calcium carbimide (Temposil) in the presence of ingested alcohol produced an acetaldehyde reaction similar to that of disulfiram and alcohol. Either citrated calcium carbimide or disulfiram plus alcohol produced flushing of the face (mal rouge), tachycardia, dyspnea, fall in blood pressure, nausea, vomiting, and sleep lasting four to six hours. In their first report, Armstrong and Kerr[5] found that 19 patients experienced no side-effects from citrated calcium carbimide given daily up to four months. In a more recent report,[6] Armstrong stated that 29 patients were kept on therapy with this drug for as long as nine months without adverse symptomatology. Several of the patients did, however, manifest an elevated white blood cell count, a finding which is currently being explored. The 64 patients treated by Bell[7] responded favorably to therapy with this drug without the toxic side-effects encountered with disulfiram. It has been demonstrated by Smith and co-workers[8] that citrated calcium carbimide exerts its effect within 30 minutes and this effect lasts 8 to 12 hours after a single dose.

Methods

The clinical use of citrated calcium carbimide in the treatment of chronic alcoholism was explored. This drug was supplied for research purposes and is not yet available on the general market. Thirty-

---

From the Department of Psychiatry, Washington Medical Center.

eight patients were given 50 mg. of the drug daily for periods up to 11 months (27 of the group had previously received disulfiram). There were 12 women and 26 men. All were ambulant and 21 were employed. A detailed history was taken and a physical examination completed prior to treatment. Psychological testing was performed when indicated. An electrocardiogram, basal metabolic rate determination, hemogram, urinalysis, determinations of fasting blood sugar level, sulfobromophthalein retention, and cephalin flocculation, and a chest x-ray were included as part of the examination.

Coronary artery disease, arrhythmia, congestive failure, severe hepatic insufficiency, or latent psychosis were considered absolute contraindications to treatment. Patients with moderately impaired hepatic function and no jaundice (sulfobromophthalein retention of 15 to 20% and cephalin flocculation of 1+ to 3+) were given citrated calcium carbimide.

All patients had been unable to stop drinking even though they had previously tried several other methods of treatment. Each agreed to remain under medical supervision for a minimum period of six months and was asked to attend meetings of Alcoholics Anonymous. A supply of drug sufficient to carry the patient to the next office visit was given with instructions to take one tablet each morning. No patient was required to undergo alcohol conditioning, and each was instructed to discontinue medication for four or five days if the desire to drink could not be controlled. All were cautioned to avoid alcohol in cough syrup, elixirs, and mouth wash.

Since constructive attitudes at home were considered important, consultation with the family was included in preliminary discussion and follow-up visits. Family members were asked to attend Alanon Family Group meetings or family guidance clinic in order to understand and help the drinking member of their family.

Results

Of the 38 patients under study, 19 (50%) were treated for a total of 164 months; no relapse occurred, and they were considered to have obtained excellent results. Eleven patients (29%) with 15 relapses and 45 months of treatment were classified as attaining satisfactory results. During treatment they improved physically, lost fewer work days, and displayed increased insight. The remaining three patients (21%), with three or more relapses each and 34 months of total treatment, were unimproved. Their pattern of drinking and their physical and emotional status were unchanged by treatment.

Two patients experienced a mild acetaldehyde reaction after ingesting alcohol. Both recovered promptly without treatment. No serious side-effects or toxic reactions were observed, and there were no deaths in the group during the period of study. The sulfobromophthalein retention was increased in 4 (10%), decreased in 9 (24%), and unchanged in 25 (66%). Leukocyte count was unchanged in 19 (50%), decreased in 5 (19%), and increased in 15 (38%). Leukocytosis was present in the latter group, with an average count of 2,000 per cubic millimeter above normal. Differential count, hemoglobin level, and erythrocyte count remained normal in all patients. No accumulative effect, lassitude, drowsiness, diminished sexual potency, altered taste, or gastrointestinal symptoms were observed. Patients with medical complications due to excessive drinking received appropriate treatment in addition to the citrated calcium carbimide and in each case responded favorably.

Summary

Thirty-eight patients with chronic alcoholism were given 50 mg. of citrated calcium carbimide daily for periods up to 11 months, with favorable response in 30 (79%). No serious side-effects and no deaths occurred. Since relative leukocytosis and increased sulfobromophthalein retention was observed in some patients, laboratory and follow-up examination are necessary until the significance of these findings can be evaluated. No patient receiving citrated calcium carbimide experienced the side-effects associated with disulfiram. This drug is a useful adjunct to other measures in the treatment of alcoholism. It provides the alcoholic patient a period of enforced abstinence during which necessary insight and understanding may be developed.

2029 Que St. N. W. (9).

The citrated calcium carbimide used in this study was supplied as Temposil by Lederle Laboratories Division, American Cyanamid Co., Pearl River, N. Y.

EVALUATION OF RANDOM BLOOD GLUCOSE LEVELS AMONG AMBULANT WOMEN

Dorothy Macy Jr., M.D., Mary E. Frank, M.D.
and
Frieda Baumann, M.D., Philadelphia

In the course of the annual diabetes detection drives from 1948 through 1956 at the Woman's Medical College of Pennsylvania, we accumulated 1,068 random blood glucose determinations, on 936 women, by the Folin-Wu method. Duplications represent different years or rechecks of questionably abnormal values; if the rechecks confirmed the presence of diabetes, only the original value was included in the series to be presented here. Ages ranged from 3 months to 79 years; 739 persons were under 40. Three hundred twelve were 5 lb. (2.3 kg.) or more overweight; 307 gave a positive family history of diabetes. There was no preparatory period of high carbohydrate intake and no standard pretest meal. The types of food taken and the time of the last meal or snack were noted. All individuals were ambulant; the degree of activity between the last feeding and venipuncture varied.

These random blood glucose levels were arranged in frequency distributions from the lowest to the highest blood glucose level at seven time intervals: fasting, one-half, one, one and one-half, two, two and one-half, and three hours after food intake. Determinations done more than three hours after eating were classified as fasting levels.

Analysis of Determinations

All seven frequency distributions were skewed to the right. One blood glucose determination was 51 mg. % at one hour; recheck was normal. This is the only value in the range of 50-59 mg. % that occurred in a series that since has totaled 1,685 cases, and we question its accuracy. If it is ignored, the lower level of the range of blood glucose values among these women becomes 65 mg. %. Since the Folin-Wu method includes 19-31 mg. % of non-glucose-reducing substances in the blood, 65 mg. % by this method represents 34-46 mg. % of true blood glucose. The reason for the relative fixation of the lower limit becomes clear: a blood glucose level persistently below this level is incompatible with human life. It is also apparent that if the frequency distributions were not skewed to the right one should suspect that a sampling error had occurred, since comparable degrees of hyperglycemia are entirely compatible with human life.

For each of the seven frequency distribution the following points were located: the nadir (lo point), the mode, the median, the arithmetic mean and the levels at or below which findings in 90, 95 96, 97, 98, and 99% of the population fell. The latte are percentile points. The mode is the value aroun which the items tend to concentrate; because it i the most typical value, it is the most descripti average. These points have been plotted on a grap (see figure) whose ordinate is blood glucose in mil ligrams per cubic centimeter and abscissa is time i minutes, and corresponding percentile points a different times have been joined by continuou curves. The nadir, mode, and what we have label the "96th percentile curve" are represented by soli lines. From the 90th to the 96th percentiles th curves show two peaks, which might be calle primary and secondary peaks, and three relati low points: fasting, two hours, and three hou after intake of food. The 97th percentile cur lacks the two-hour low point. The 98th percentil curve shows a peak in place of the two-hour lo point and a rising tendency in place of the thre hour low point. In brief, for this particular population a change in the general contour of the upp percentile curves begins at the 97th percentile an is further accentuated above it.

Comment

The purpose of this presentation is to show th range of blood glucose levels which occurred i the population which was studied and the percen age of the population which fell within any give limits. Blood glucose homeostasis is a dynamic stat it is an open system, constantly receiving materi from and releasing material to its environment, b it is a system which has boundaries. The boundaries are determined by the fact that, when the limits of such a steady state are exceeded, the stat disappears—in this instance the state disappea when the capacity to return spontaneously towa the median is lost (irreversible hypoglycemia, fulminating hyperglycemia). These limits are not absolutes; the level of blood glucose at any give moment is the net result of multiple simultaneo variables, some of which are interdependent, an whose effects may be positive or negative; th limits are functions of the variables. Among apparently normal individuals one encounters isolated

even occasional elevations of blood glucose to levels which usually connote diabetes; among diabetics, there are those who neither take insulin nor follow any dietary regimen yet under many conditions have blood glucose levels within the accepted "normal" range. Under fasting conditions, when the glucose load is minimal, there is a marked overlap among blood glucose levels of diabetic and nondiabetic individuals.

Observation of all possible combinations of variables would be necessary to determine the boundaries of an open system. This is impractical, and

one can only approximate those boundaries by making a definite number of observations on spontaneously occurring combinations of variables. This approximation to the boundaries of blood glucose homeostasis is a crude estimate of the probability of the maintenance of the steady state. The mode, in turn, is an approximation to the most typical level of blood glucose, toward which the system tends no matter what the variables.

Returning to the figure, it can be seen that the blood glucose levels represented in the 97th and 98th percentiles fall in a range not uncommonly seen among untreated persons with mild diabetes in the absence of complications. Of the population screened, 3.9% had blood glucose levels above the 96th percentile curve, the highest percentile to conform with the 90th, an upper percentile which reflects normality since we know that less than 10% of the population is diabetic. The incidence of diabetes among the population as a whole in the United States has been estimated to be about 2%. The population represented in the figure was exclusively female, one-third over 40 years of age, one-third overweight, and one-third with a positive family history of diabetes—all situations in which diabetes is more common—so that an incidence of 3.9% in such a group is not utterly improbable. The correlation between clinically established facts and the range in which atypical contours appear in the percentile curves suggest that the region of these changing contours marks the usual range of the upper limit of blood glucose homeostasis for the particular population screened, i. e., ambulant women. It must be emphasized that if one were screening a different population—overweight women only, thin women only, or some other group—the region of changing contours of upper percentile curves would not necessarily be identical. In fact, where physiological differences which influence carbohydrate metabolism exist between two groups, the contours of the percentile curves would necessarily be different; when the components of the system are changed, the conditions for homeostasis are changed. If the combinations of variables which are included in the system under observation have been limited, the result is to define a limited portion within the general steady state. The identification of the zone between normal and abnormal depends on the contours of the curves in relation to time, which reveals whether the system is tending to maintain itself.

If this reasoning is valid, we have in the data presented here a useful empirical criterion for the specific situation of random blood glucose levels among ambulant women and, in addition, a general method for the evaluation of certain types of steady states in biology. Confirmation or refutation of the validity of the method rests on further empirical observation.

Summary

Blood glucose levels were determined by the Folin-Wu method on 1,068 blood specimens drawn from an apparently well female population which ranged in age from 3 months to 79 years. Samples were obtained in the fasting state and up to three hours after intake of food. There was no preparatory period of high carbohydrate intake and no standard pretest meal. Results were arranged in frequency distributions at 30-minute intervals. The nadir, mode, median, and mean and the 90th, 95th, 96th, 97th, 98th, and 99th percentile points were located for each group; corresponding points at the different time intervals were joined by continuous curves. The curves represent blood glucose levels as these actually occur among ambulant women under usual conditions. It is suggested that the range between the nadir and the 96th percentile curve represents the range of blood glucose homeostasis under these conditions and that the 97th percentile and above represents diabetes mellitus. It is shown that there is a level of blood glucose toward which the system tends no matter what the variables (such as food and exercise).

This method of evaluating random blood glucose levels yields an approximation to the boundaries of blood glucose homeostasis for the particular population observed. It is a method for estimating the probability of the maintenance of the steady state and, hence, a potentially useful method for the study of such states. The validity of the method can be determined only by further observation.

GLAUCOMA.—Although there has been long recognized danger of glaucoma in patients being treated with the usual belladonna-like drugs, the neurologic literature is empty of such reports in the treatment of Parkinsonism. In a random sample of Parkinson patients studied by means of recording intraocular tension, only one minimally abnormal value was obtained and no patient experienced any subjective symptoms suggestive of glaucoma. It would appear that the predisposition to glaucoma in the individual patient is of far more importance than the mere use of a parasympatholytic anti-Parkinson drug. If the neurologist takes a careful initial and follow-up history, the danger of his patients with Parkinson's disease or syndrome developing glaucoma is quite small.—C. F. Edwards, M.D., and D. S. O'Doherty, M.D., Anti-Parkinson Drugs and Their Relationship to Glaucoma, *Bulletin Georgetown University Medical Center,* September, 1958.

CHRONIC RECURRING SPONTANEOUS PNEUMOTHORAX DUE TO ENDOMETRIOSIS OF THE DIAPHRAGM

Elmer R. Maurer, M.D., James A. Schaal, M.D.
and
F. L. Mendez Jr., M.D., Cincinnati

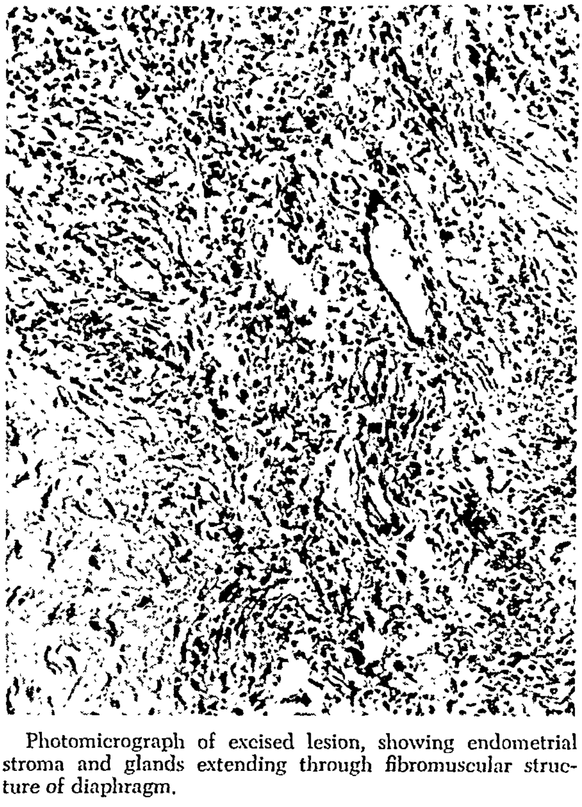
Chronic recurring spontaneous pneumothorax is a relatively common disorder which usually results from rupture of subpleural blebs. Endometriosis of the diaphragm, on the other hand, is an exceedingly rare lesion and, as nearly as can be determined, has never been reported in association with, or as a cause of, unilateral recurring pneumothorax.

The following case report is presented because of the extreme rarity of the lesion involved and the unusual association of pneumothorax with the menstrual cycle. It is the first recorded instance of successful surgical treatment of chronic recurring pneumothorax by excision of a defect in the diaphragm that has resulted from endometriosis.

Report of a Case

A 35-year-old woman was first seen in consultation on March 13, 1953, because of pain and dyspnea resulting from a spontaneous pneumothorax on the right side. The patient had had two previous spontaneous pneumothoraces on the right, the first having occurred on Nov. 14, 1952. Findings on the general physical examination were negative except for distant breath sounds over the upper right part of the chest and hyperresonance of the percussion note due to a pneumothorax. Roentgenograms of the chest revealed a very minimal pneumothorax (15%) over the extreme apex and the base of the right lung. No emphysematous blebs were apparent in any portion of either lung. Because of the small quantity of air in the chest and the absence of serious symptoms, removal of the air by thoracentesis or tube thoracostomy was not thought to be indicated. The patient was discharged from the hospital for follow-up care by her attending physician. She was again seen in consultation on March 20, 1954, approximately one year after the original examination, because of 12 new episodes of recurrent pneumothorax on the right side. All pneumothoraces were associated with pain and mild dyspnea and had been verified by roentgenographic examination of the chest. For the first time, the patient volunteered the information that all 15 episodes of spontaneous pneumothorax had come during the period of menstruation. The important clinical significance of this observation was not appreciated at the time. Because of the chronicity of the lesion, open thoracotomy with possible talc poudrage and excision of any blebs that may not have been apparent on roentgenographic examination was recommended.

Right thoracotomy on March 31, 1954, revealed a persistent moderate pneumothorax on the right side. Careful examination of all lobes of the right lung revealed no evidence of blebs. Testing of the lung with positive pressure, while saline solution was dripped over the surface, disclosed no points of air-leak. The lung parenchyma grossly presented a normal appearance and consistency. The most remarkable finding involved the right diaphragm. Near the point of emergence of the inferior vena cava and extending radially and laterally in the central portion of the right leaf of the diaphragm was a circumscribed, oval-shaped area of attenuation which measured 4 by 3 cm. in diameter. Numerous purplish-red nodulations were apparent on this surface. In the central portion of the diseased area in the diaphragm was an aperture 2 cm. in diameter. This communicated freely with the peritoneal cavity. The area of disease in the diaphragm, along with the defect, was widely and completely excised. The consequent diaphragmatic opening was repaired with interrupted mattress sutures of cotton, size 0. Examination of the specimen showed that the disease had involved the complete thickness of the diaphragm. Final inspection of the superior surface of the diaphragm revealed a solitary purplish-red nodule, 1 cm. in diameter, which obviously represented a supradiaphragmatic endometrial implant. This also was completely excised. Following reexpansion of the lung and the placement of an intrapleural catheter for water seal drainage, the chest wall was closed in layers. The postoperative diagnosis was endometriosis of the right leaf of the diaphragm resulting in perforation and implant of endometrial nodules on the intrathoracic surface of the diaphragm. Microscopic examination of the surgical specimen showed extensive involvement of the fibromuscular stroma of the diaphragm by nests of endometrial stroma and glands (see figure). The single nodule on the supradiaphragmatic surface was composed of endometrial tissue.



Photomicrograph of excised lesion, showing endometrial stroma and glands extending through fibromuscular structure of diaphragm.

The postoperative course of the patient was entirely uneventful, and she was discharged from the hospital on her ninth postoperative day, being afebrile and ambulant, and with her right lung completely expanded.

Because of pain in the pelvis and dysmenorrhea, the patient was seen by a gynecologic consultant. Bimanual examination revealed adherence of the fundus and nodules throughout the adnexa. A diagnosis of pelvic endometriosis was made, and on Aug. 18, 1955, total hysterectomy with bilateral salpingo-oophorectomy was performed. The patient's postoperative recovery was again uneventful. In the four and one-half years after the thoracotomy, the patient has had no recurrent chest symptoms or pneumothorax.

Comment

Aberrant endometrial islands have been reported in many locations, including the ovaries, uterine ligaments, rectovaginal septum, sigmoid colon, urinary bladder, umbilicus, laparotomy scars, hernia sacs, appendix, vagina, vulva, cervix, lymph glands, and small intestine, and in bizarre locations, such as the upper and lower extremities, lungs, and pleura.[1] Sampson's [2] original theory of transtubal regurgitation of menstrual blood and endometrial particles, published in his original paper in 1921, could certainly explain the method of implantation of endometrial growths on the pelvic and intra-abdominal viscera, as well as on the inferior aspects of either leaf of the diaphragm. The lymphatic and hematogenous dissemination theory of Halban would be necessary to explain distant endometrial implants in the thigh, lung, and pleura.[1a] Distant spread without passing through the pulmonary capillaries could occur only by way of the vertebral veins or "lung shunts" which have apparently been demonstrated between the pulmonary arteries and veins bypassing the lung capillaries.

In view of the concomitant finding of pelvic endometriosis and the involvement of all layers of the right leaf of the diaphragm, with perforation and supradiaphragmatic seeding demonstrated by thoracotomy, in the present case report, it would seem logical to conclude that the endometrial involvement of the diaphragm must of necessity have occurred as the result of transtubal regurgitation and transperitoneal dissemination. Exact explanation of the method of development of the pneumothorax on the right side is more difficult. However, the clinical observation that all episodes of pneumothorax occurred only during the time of menstruation, and the inability to demonstrate any source of lung leak or primary disorder in the lung which could explain any possible leakage of air into the pleural cavity, would suggest that the recurrent pneumothoraces in the case reported here were the result of erosion and perforation of the right diaphragmatic leaf by endometrial implant and the passage of air from the uterus by way of the fallopian tubes into the peritoneal cavity and then by way of the opening in the diaphragm into the pleural cavity, with consequent pneumothorax. Although we are unable to find any reports of spontaneous pneumoperitoneum occurring during the menstrual cycle, the practical possibility of this is suggested by the free anatomic communication between the cavity of the uterus with the peritoneal space by way of the fallopian tubes. Practical application of this knowledge is regularly used in the so-called Rubin test for patency of the tubes. During this procedure, carbon dioxide is passed into the uterus and then by way of the tubes into the peritoneal cavity. During the test, patients may experience shoulder pain and present roentgenographic evidence of pneumoperitoneum.

Summary

Chronic recurring pneumothoraces resulting from erosion of the diaphragm by endometrial implants during periods of menstruation occurred in a young woman. This was surgically corrected by excision of the involved portion of the diaphragm. The unanticipated findings encountered at operation in this patient present an additional indication for exploratory thoracotomy in all cases of unexplained, constantly recurring, spontaneous pneumothorax.

THE FUNCTION OF THE BRAIN.—Any biological view of the function of the brain leads us to an unavoidable conclusion: consciousness is not unique to man, to the primates, or to the mammals: it goes back to the roots of vertebrate history and has been progressively elaborated in content, coloring and complexity roughly in proportion to the evolution of the neuromuscular system. It cannot even be argued that consciousness is a unique vertebrate invention—the crab, the octopus, the butterfly, the ant, all possess sensory devices imparting to them the awareness of their world; all demonstrably engage in integrated time-binding, self-serving action, and it must be presumed that all participate in some proportional measures in conscious awareness of themselves and their environment.—H. HEREDITARY GALACTOSE DISEASE

George M. Guest, M.D., Cincinnati

Galactosemia and galactosuria characterize a hereditary disease caused by an inborn error of metabolism, which produces in an affected child the inability to metabolize galactose and lactose normally. Some appropriate terms that have been suggested and used synonymously are galactose diabetes, essential galactosuria, congenital galactosemia, congenital galactosuria, galactosis, and galactemia.[1] The term used here, galactose disease, is favored by Kalckar and his associates[2] who have recently done outstanding work on the fundamental etiology of the disorder.

Cases of this disease were first described in Germany by von Reuss[3] in 1908 and by Göppert[4] in 1917, and first in the United States by Mason and Turner[5] in 1935. In 1946, Goldbloom and Brickman[1a] counted only seven previously reported cases when reporting two more. Since then, reports have appeared with increasing frequency; it now seems obvious that the disease is much more common than is generally believed. It is characterized by multiple manifestations, of varying severity, all presenting challenges to the biochemist, pathologist, clinician, and dietitian. The great importance of early recognition of galactosuria lies in the fact that deleterious effects of the disorder increase with its duration and that appropriate treatment (omission of milk from the diet) usually leads to prompt diminution or total disappearance of its various abnormal manifestations and to a good prognosis.

Clinical Signs and Symptoms

The main symptoms of the disease appear early, usually when the infant is one or two weeks old; in 90% of reported cases they were recognized within the first year of the infant's life. Jaundice, persisting far beyond the usual period of so-called physiological jaundice of the newborn infant, may constitute an early sign that more serious trouble is impending. Neonatal bleeding has been reported as an early complication.[6] This might conceivably result from liver damage, with lowered prothrombin and fibrinogen levels in the blood, but these factors seem to have been little studied. Goldbloom and Brickman[1a] reported low values for serum globulin in two infants. The course can be fulminant, with rapid development of hepatomegaly, splenomegaly, and ascites. Hyperchloremic acidosis has been observed, with low serum potassium level.[7] Death may occur within a few weeks or months.

On the other hand, the course may be slow, as in the child reported by Ritter and Cannon,[8] in whom the cataracts and other features of the disease were not recognized clinically until she was five years old. The history of the slower course usually includes a report of slow growth or growth failure, feeding difficulties characterized by refusal of food, regurgitation, or vomiting, and sometimes diarrhea with yellow stools. Cataracts usually develop within the first year and have been reported as early as the 13th day of life. Mental retardation becomes apparent with increasing age of the untreated infant. Hypochromic anemia, reported by some investigators, may be a secondary result of feeding difficulties that can aggravate the tendencies to develop iron deficiency existing even in normal infants during the first and second years. Urinalysis reveals varying degrees of melituria, albuminuria, and aminoaciduria.

Heredity

Although it is generally accepted that galactose disease is determined genetically, its exact mode of transmission is not yet clearly defined. A positive or suggestive history of the disease among direct or collateral relatives has been elicited in about 30% of the reported cases. In several instances, the disease has occurred in more than one sibling in a family. There is no evidence of sex linkage. In one pair of parents consanguinity was reported.

Holzel and Komrower[9] searched for evidence of the trait in seemingly unaffected persons by performing galactose tolerance tests among parents and relatives of galactosemic infants in five families. Reduced tolerance for galactose as revealed by this test was found in at least one parent of each child with clinical galactosemia and in both parents in one instance. Three of six siblings, free of recog-

---

nizable signs of the disease, showed abnormal galactose tolerance curves. It seemed, therefore, that heterozygous carriers of the trait, who had no clinically notable manifestations, could be detected by their abnormal responses to the galactose tolerance test. These observations were interpreted to indicate that inheritance of galactose disease is recessive, the overt form of the disease being manifested in individuals who are homozygous, with regard to the abnormal gene. An uncertainty of this argument lay in the fact that abnormal tolerance was not demonstrable in both parents of all children with the overt disease; but, as the authors point out, probably the test is not sufficiently sensitive to demonstrate an incomplete metabolic block. Holzel and Komrower[9] suggest that this trait is much more common than was originally believed and that the gene is likely to become more widespread with improved treatment of the overt manifestations of the disease and with increasing survival of homozygous babies.

The galactose tolerance test has, of course, long been used as an index of liver function in both acute and chronic liver disease. Hartmann and co-workers[6] reported cases of transient galactosemia and galactose intolerance occurring in young infants associated with diarrheal disease, malnutrition, and immaturity. Although the intolerance was regarded as a complication of the associated diseases, the possibility of a partial metabolic block of true galactose disease must be considered in the light of Holzel and Komrower's concept of the heterozygous carrier with minimal physical manifestations of galactose disease. In such cases the associated diseases, acute or chronic, might conceivably act to aggravate an existing mild intolerance of galactose, genetically determined. Against this possibility Hartmann points out that the galactose tolerance curves of these infants became normal after recovery from their acute diseases.[10] This fact, however, would not necessarily exclude the existence of a partial metabolic block.[10]

Pathology

In patients with active clinical manifestations of galactosemia, anatomic changes are most prominent in the liver, kidneys, and the lens. The liver shows areas of cellular degeneration and necrosis, with bile stasis, abnormal pseudoacinar grouping of the hepatic cells, sometimes with fatty metamorphosis.[11] If the patient survives long enough, two types of cirrhosis may develop: the micronodular Laënnec's type and cirrhosis associated with postnecrotic scarring.[12] The kidneys may show swelling of the tubular epithelium, with the cells containing what is often described as glycogen but which some investigators have suggested might be galactogen. B. H. Landing[13] states, however, that, in some tissue sections which he examined, the material did not have the staining characteristics of galactogen. Cataracts in the lens may display either lamellar or central nuclear opacities.[1a]

The cause of the cellular changes is by no means clear. Evidence of direct toxic effects of galactose has been adduced from Dam's[14] experiments in which feeding of a high-galactose diet to chicks led to damage of the central nervous system; evidence is also available from experiments on rats, in which feeding high-lactose rations led to the development of cataracts.[15] The latest and most plausible suggestion is that cellular damage is not caused by the galactose per se but by the cellular accumulation of galactose-1-phosphate, which has been found to inhibit several enzyme systems.

No obvious histological signs of cellular damage in the brain have been described to account for the commonly observed mental retardation.[16] Evidence of brain damage is limited to functional observations, but, because the disease varies so much in its severity in different individuals, such evidence is difficult to interpret. Speculating on the nature of the impairment of central nervous system function that leads to mental retardation in galactosemic children, Mason and Turner[5] suggested that the hypoglucosemia which is often found with hypergalactosemia might lead to cellular damage, especially in the brain. The fact that other types of hypoglycemia, acute and chronic, do not produce this kind of clinical picture makes this hypothesis doubtful.[17]

The mentally deficient galactosemic child does not present neurological symptoms like those that develop after severe hypoglycemia (such as changes in the electroencephalogram). It is true that reciprocal changes in concentration of glucose and galactose in the blood occur during a galactose tolerance test and after a mixed meal containing milk. This shift may be a result of competition between galactose and glucose both in the intestinal mucosa during simultaneous absorption of the two sugars and in the enzyme systems of liver and other tissue, but the concomitant effects and consequences are not clear.

It has been suggested that defective utilization of galactose may interfere with the synthesis of galactolipids, cerebrosides that are involved in the rapid myelinization which normally occurs in the first few weeks or months of life. Some investigators suggest that complete exclusion of galactose from the diet as part of treatment might have later deleterious effects, making the children more susceptible to demyelinating disease. Against this possibility, Holzel and associates[7] pointed out that the galactose required for synthesis of cerebrosides can be derived in situ from glucose by reactions in which the intermediation only of uridinediphosphogalactose (UDP galactose) and galacto-waldenase (later named UDP Gal-4-epimerase) is needed; these enzymes are available in the galactosemic child.

There is abundant evidence that, if therapy is begun early, the severe physical manifestations of the disease may be prevented, or reversed if already developed, especially with regard to liver damage and cataracts, but the complete prevention of mental retardation is less certain. In several reported cases in which treatment began early, the mental development of affected children is said to be normal.

Biochemical Pattern and Diagnostic Procedures

If the infant is taking a milk diet, a reducing substance is invariably to be found in the urine, although not necessarily in every specimen. It is important to note that, when meliuria is observed in a young infant, the diagnosis of galactosuria should be considered before that of diabetes mellitus, the incidence of the former being at least four or five times more frequent.

For the differential diagnosis of melituria, the recently available glucose oxidase methods have great practical value in excluding glucosuria. The specific enzyme, glucose oxidase, has been incorporated in indicator papers. These were offered primarily for qualitative tests for glucose in urine in diabetic management; but aside from that use, the test is applicable for quick differential diagnosis of other types of melituria. When dipped in urine, these test papers turn blue in the presence of glucose but remain unchanged if glucose is not present. The test is negative with all reducing sugars other than glucose. In several instances, when infants were sent to the Cincinnati Children's Hospital with a tentative diagnosis of diabetes mellitus, because so-called sugar had been found in the urine, the receiving physician, by means of this simple test, was able quickly to exclude the diagnosis of diabetes; on the basis of history and physical findings, the tentative diagnosis was changed in the admitting room to galactosuria or to fructosuria (the latter associated with evidence of acute hepatitis), diagnoses that were later confirmed by chromatographic methods.

For identification of reducing substances in the urine, the fermentation tests with yeast, much used in the past, may yield presumptive evidence that the sugar is not glucose or fructose, i. e., most likely galactose, but it must be remembered that some yeasts do ferment galactose. Relatively simple techniques for paper chromatographic methods for the identification of sugars and amino acids in the urine have been described by Bickel and Hickmans,[1c] Hsia and associates,[18] and Lockhart and Roboz.[19]

Aminoaciduria is an important feature of the pattern of biochemical disturbances that accompany galactosuria.[20] When galactosemic children are receiving a milk diet and showing galactosuria, the excretion of amino acids is greatly increased. It is generally said to be due to diminished tubular resorption of amino acids resulting from renal irritation by the excreted galactose.[20a] The increased excretion is general, including all the amino acids usually found in the urine of normal infants. In a few cases studied in Cincinnati, the hydroxyamino acids, serine and threonine especially, appeared to be disproportionately increased. That aminoaciduria may be slow to develop after galactosuria is demonstrable, but it is also slow to disappear after galactose is eliminated from the diet and galactosuria has ceased. The concentration of amino acids in the blood appears not to be increased above normal.

Hsia and associates[18] and Holzel and associates[20b] reported studies of aminoaciduria in galactosemic children, first in a seemingly normal state after a long period on a galactose-free diet and then after galactose was added to the diet. Before this test, the amino acid excretion was similar to that of normal children, but, after galactose was added to the diet, the amino acid excretion increased twofold to fivefold. This returned to normal again after administration of galactose had been discontinued for 10 days. In Cincinnati we have made similar observations. Hsia found the increased aminoaciduria to be generalized, without any single amino acid being excessively prominent. Speculations on the biochemical mechanisms that are involved have dealt with questions of competition between enzyme systems and of toxic effects of galactose and its intermediate products of metabolism on various tissue cells but without definitive conclusions. The fact that several of the essential amino acids were excreted in considerable quantities may have a bearing on the manifestations of nutritional deficiency that develop in this disease when it is uncontrolled, but the quantitative importance of such losses is not defined.

A most important recent development in this field is the discovery that the inability to metabolize galactose in congenital galactosemia is due to the absence in liver and blood cells (probably in all tissues) of a single specific enzyme, which is normally involved in the conversion of galactose to glucose. Normally, galactose is metabolized by phosphorylation to galactose-1-phosphate by galactokinase and adenosinetriphosphate; the galactose-1-phosphate is, in turn, converted to glucose-1-phosphate by reactions that involve a nucleotide, uridine-glucose-diphosphate, and two specific enzymes, galactose-1-phosphate uridyl transferase and galacto-waldenase. Earlier, Schwarz[21] and coworkers in England reported that galactosemic red blood cells, when incubated with galactose, accumulated galactose-1-phosphate, whereas normal red blood cells did not. Subsequent work at the National Institutes of Health revealed that the accumulation of galactose-1-phosphate in the galactosemia cells was due to absence in the cells of the specific enzyme, galactose-1-phosphate uridyl transferase.[22] Thus, it appears that "the gene or genes responsible for galactosemia control the synthesis of P-galactose-uridyl transferase in the cells."[7]

These studies led to the development of a specific diagnostic test for congenital galactosemia.[23] This test can be done satisfactorily on the erythocytes of newborn infants, even from cord blood,[22a] thus affording a feasible procedure for earliest possible diagnosis of galactose disease when the family history suggests that it might be expected in the new offspring. Kirckman and Kalckar have now modified the test in such a way that it can be used for the detection of so-called traits. They found that parents (usually both) of galactosemic children have a markedly lowered activity of galactose-1-phosphate uridyl transferase in the red blood cells.

Effects of Treatment

When galactose is eliminated from the diet of a galactosemic infant, the level of galactose in the blood falls quickly, proteinuria ceases, and the level of amino acids in the urine decreases to amounts found in the urine of normal infants. After this, the infant gains weight, hepatomegaly gradually diminishes, jaundice disappears slowly or quickly, and opacities of the lens, if present, gradually clear. After such apparently complete recovery, resumption of milk feeding even for a short period may provoke a return of all symptoms, with vomiting, albuminuria, and aminoaciduria, that again disappear when milk is withheld. With increasing age of the child, the galactose tolerance test shows a persistent abnormality, although the child may become progressively less sensitive to breaks in the dietary regimen. Among different individuals, incomplete enzyme deficiency or availability of alternate pathways of galactose metabolism may account for differences in the clinical picture. With increasing age of the child, the functional maturity of organ systems that are injured by the cellular accumulation of galactose-1-phosphate also may account for changes in sensitivity to galactose.

The need for early diagnosis and treatment of galactosemia cannot be overemphasized. There is abundant reason to believe that the danger of damage to the central nervous system in this disease is greatest during the first few weeks or months of the infant's life, the period of most rapid growth and development of the brain. Here the importance of early treatment is comparable to that of certain other metabolic diseases that are known to be associated with mental retardation in children, e. g., cretinism and phenylketonuria.

With regard to cretinism, it is well known that the earliest possible administration of thyroid extract to the athyroid infant favors both physical and mental growth and development, whereas later treatment may promote improved physical development but with less or no effect on mental retardation. In phenylketonuria, rapidly accumulating evidence currently indicates that the administration of phenylalanine-restricted diets to the phenylketonuric infant at an early age, preferably under 2 months and before the appearance of any signs or symptoms of abnormality, may allow normal mental and neurological development.[24] However, if the restricted diet is started when the child is older than 3 years and if signs of mental retardation and convulsions are fully developed, there is little or no objective evidence that the diet is beneficial.

In phenylketonuria, as in galactose disease, the mechanisms responsible for central nervous system damage are not yet clearly defined. It has been claimed that brain damage may occur as a result of secondary deficiencies of essential amino acids or other food elements or as a result of neurotoxic agents formed as products of the intermediary metabolism of phenylalanine. It appears that after about 3 years of age the infants who were successfully treated with the phenylalanine-restricted diet can be fed a normal unrestricted diet without risk of further brain damage. Armstrong notes the probability that the extent of early damage influences the effect of the deleterious metabolites, as indicated by the fact that older, untreated phenylketonurics with milder biochemical abnormalities can be mentally normal. Such reasoning may equally apply to galactosemic infants who are treated early and develop normally, and to those who are treated late and exhibit evidences of more or less severe mental retardation which persists, despite a galactose-restricted diet.

Treatment

Treatment is directed toward rigid exclusion of galactose from the diet by withholding milk, especially human milk with its high galactose content. For young infants, liquid formulas may be made up with casein hydrolysate preparations such as Nutramigen. Numerous investigators have reported good results after the use of soy-bean products (such as Mul-Soy or Sobee) as a milk substitute, but Holzel and co-workers point out that soy beans contain stachyose, which is a tetrasaccharide with two molecules of galactose; theoretically, therefore, these preparations should be avoided, but no one has yet measured just how much galactose is liberated from the stachyose during digestion.[25] Holzel claims that some sensitive infants may fail to thrive and may suffer continued brain damage when the diet contains only a trace of galactose, insufficient to show in the blood and urine.

When solid foods are added to the diet, care must be taken not to include foods prepared with milk or those that have lactose added. Acceptable foods are cereals (offered, of course, without milk), vegetables, eggs, fruits, meats, gelatin puddings (made without milk), and bread or crackers (if made without milk). Goldbloom recommended washed milk curds resuspended in Ringer's solution, sweetened with corn sirup. It should be noted that cheese and milk curds may contain around 1% of galactose, and butter may have 0.2% of galactose. Vitamin C tablets and other medicinal tablets are often made up with lactose, and some commercially prepared cereals contain lactose, added during the manufacturing process. The diet should be supplemented with sufficient amounts of vitamins to supply the quantities recommended for normal infants; calcium, either as chloride or gluconate, should be added to supplement the low-calcium content of the milk-free diet and fruit juices to augment the potassium intake.[26] Holzel and associates recommend Moll's pudding, prepared of cereal, sugars, eggs, margarine, and cane sugar.[25a]

Summary

Early diagnosis and treatment of hereditary galactose disease is of the greatest importance since the deleterious effects of this disorder increase with its duration. The main symptoms usually appear by the time the infant is one or two weeks of age, making early recognition possible. Appropriate treatment is primarily the omission of milk and other foods containing galactose from the diet. Early therapy may prevent or reverse the severe physical manifestations of this disease, and it is likely, although not certain, that mental retardation may be completely prevented.

Indicator papers for differential diagnosis of meliturias are available as Testape from Eli Lilly & Company and as Clinstix from the Ames Company, Inc.

Reagents for enzymatic test for the specific diagnosis of congenital galactosemia are available from the Sigma Chemical Co.

PRODUCTION OF CONGENITAL MALFORMATIONS BY DIETARY MEASURES

EXPERIMENTS IN MAMMALS

Josef Warkany, M.D., Cincinnati

In recent years there has been increasing interest in questions connected with the origin of congenital malformations, and unusual attention has been focused on animal experiments that result in deformed offspring. Experimental production of congenital malformations in lower animals has been possible for many decades, but systematic modification of mammalian embryos became practicable only during the last 25 years. Many methods are now available that permit production of congenital malformations in mammals, and among these are nutritional experiments that have been widely used as an instrument of teratological research.

As early as 1933, Hale[1] demonstrated that congenital malformations can be induced in pigs by a deficient maternal diet. In these experiments gilts of known stock were fed a diet deficient in vitamin A and possibly also deficient in other nutritional factors. The offspring showed microphthalmia or anophthalmos, accessory ears, cleft palate with harelip, and ectopic kidneys. In control animals Hale showed that supplementation with cod liver oil or green fodder prevented the anomalies. He also ruled out genetic determination of these malformations by matings of abnormal sons to their mothers or of abnormal brothers to their abnormal sisters. If the females were fed an adequate diet during pregnancy, such matings always resulted in normal offspring.

Results of Various Vitamin Deficiencies

Riboflavin.—Extensive studies in small laboratory animals were made possible when my associates and I found that a syndrome of skeletal malformations could be induced in rats[2] by maternal riboflavin deficiency.[3] Under strict experimental conditions, about one-third of the young were found to be abnormal. There was often shortness of the tibia, fibula, radius, ulna, and mandible and fusion of the ribs. Cleft palate was present in about
of the abnormal young. Since hundreds o
tive offspring were obtainable with this me
was possible to study the differing suscept
of the various skeletal elements, to obse
histological changes in bone and cartilage,
determine the time in gestation when the v
deficiency changed the development of the a
structures.[4] These experiments showed that
metrical and "familial" congenital malform-
could be induced in mammals by environ
conditions, a possibility denied by many gene
up to that time. The studies demonstrated t
high incidence of posterior cleft palate (wi
harelip), an internal skeletal malformation, ca
induced by a chemical deficiency in stocks o
that were free of the anomaly. In these experi
maternal riboflavin deficiency resulted chiefl
skeletal malformations in the offspring, wh
soft-tissue anomalies were very rare.[3]

Vitamin A.—Since Hale had produced malfo
tions in pigs by maternal vitamin A deficie
attempts were also made to breed female rat
pleted of vitamin A. In these experiments, the
pective mothers were given a diet low in vitam
from the time of weaning, but carotene was a
in small and measured amounts to make gr
and maturation possible. After breeding, th
males were given a diet free of vitamin A. A
drome of congenital malformations was induce
a high percentage of the young. The eyes,[5]
urogenital tract,[6] the diaphragm, the heart, and
aortic arches[7] were chiefly involved; striking ske
tal malformations, such as those produced by rib
flavin deficiency, were absent. It is possible th
to study in rats the morphogenesis of certain m
formations of the eye, the great vessels, the hea
and the kidneys. These experiments also shed lig
on some theoretical questions of prenatal physi
ogy. For instance, the fact that fetuses under
days did not show the classical signs of vitamin

From the Children's Hospital Research Foundation and the Department of Pediatrics, College of Medicine, University of Cincinnati.

deficiency, namely, keratinizing epithelial metaplasia, and that older fetuses did exhibit these signs illustrates that differing fetal age groups react differently to the same deficiency. The fact that an experimental procedure, such as prenatal vitamin A deficiency, could induce malformations of the genital ducts and of the urogenital sinus in both male and female young proved of interest to those investigating the origins of pseudohermaphroditism.[6]

Vitamin B Complex.—Although early experiments in riboflavin deficiency did not result regularly in malformations of soft tissues, prenatal deficiencies in other vitamins of the B complex did. Hogan and co-workers[8] observed that a maternal diet deficient in folic acid and cyanocobalamin (vitamin B_{12}) induced a high incidence of hydrocephalus in infant rats, and Lefebvres-Boisselot[9] produced exencephaly and ocular defects by pantothenic acid deficiency.

Vitamin E.—Most of the deficiency experiments cited thus far were simple depletion experiments. In later experiments, it was shown that it was sometimes necessary to limit the depletion period to early pregnancy and to feed an adequate diet later, so that the deformed fetuses could live to term. Such a procedure had to be employed to obtain malformations by vitamin E deficiency. As a rule, vitamin E deficiency in pregnant rats results in fetal absorption[10]; however, survival of fetuses can be achieved if the deficient maternal diet is supplemented by vitamin E on days 9, 10, and 11 of gestation. Supplements with vitamin E in midpregnancy salvage some of the embryos damaged by the deficiency during early organogenesis, resulting in the birth of young, with malformations.[11]

Role of Antimetabolites

The introduction of antimetabolites into nutritional teratology represented a significant step forward. The early experiments in which dietary depletion was practiced were laborious and delicate, since with this method it was difficult to create borderline deficiencies that would injure the developing embryo without killing it. The depletion period necessary before the females could be bred extended over weeks or even months. When, for instance, a diet deficient in riboflavin was fed only during gestation, but not before, the resulting depletion was insufficient to produce congenital malformations in the young rats. However, when Nelson and co-workers[12] added the antimetabolite galactoflavin to such a diet, deficiency could be created within a few days. In this way it became possible to begin the experiments at or even after conception and to omit the long preparatory periods, and malformations could be produced in 64% of the offspring. Compared with the original procedure,[2] the yield of abnormal offspring could be doubled. In general, the skeletal malformations produced by combination of a diet deficient in riboflavin plus administration of galactoflavin were identical with those produced in earlier experiments by riboflavin deficiency alone. However, the addition of galactoflavin did change the syndrome, since soft-tissue malformations occurred in more than one-third of the abnormal young animals.[12]

Folic acid (pteroylglutamic acid, PGA) deficiency was developed into a most efficient teratogenic instrument. Giroud and Lefebvres-Boisselot[13] added 5% succinylsulfathiazole (Sulfasuxidine) as an intestinal antibiotic to a maternal diet deficient in folic acid and obtained young with eye and brain defects, harelip, and other facial anomalies. Nelson and co-workers[14] employed a purified diet deficient in folic acid, containing 1% succinylsulfathiazole and 0.5% x-methylfolic acid, a crude folic acid antagonist. This diet was capable of rapidly producing a deficiency of folic acid and a high incidence of congenital malformations in the young rats. For instance, when this diet was fed for three days (days 9, 10, and 11 of pregnancy), a great variety of malformations could be obtained in 99% of the offspring. Multiple skeletal defects, cardiovascular, ocular, and urogenital anomalies, and abdominal and diaphragmatic hernias were observed. When this diet was fed on the 10th to 13th days of gestation, 100% of the offspring had cleft palate. In addition, many had other skeletal defects and urogenital anomalies. The types and incidence of congenital anomalies resulting from a transitory deficiency period of a few days varied with the time of instituting the deficiency and with its duration and severity.[15] The high yield of abnormal young obtained by this rapid treatment can probably be attributed to the fact that the embryo can be severely injured by the deficiency of folic acid, whereas the mothers are not adversely affected. This deficiency effect makes possible the survival of a large number of deformed fetuses in the uterus of mothers who remain in good health and gain weight during the short experimental period.

The teratogenic power of folic acid antagonists is also demonstrated by the effects of aminopterin (4-aminofolic acid) on embryos of mothers receiving adequate diets. Thiersch[16] observed hydrocephalus, meningo-encephalocele, harelip, and cleft palate in human embryos whose mothers had been given aminopterin to induce therapeutic abortion. Other antimetabolites with teratogenic action have been examined in experimental animals.[17]

Teratological Effect of Hypervitaminosis A

Cohlan's[18] interesting discovery that hypervitaminosis A is teratogenic must be mentioned briefly. Huge doses of vitamin A administered to pregnant rats during organogenesis produced malformations in many of the young. Exencephaly, hydrocephalus, spina bifida, ocular defects, cleft palate, and other skeletal malformations were observed as the result of this treatment. Although the mode of action of this agent is not clear, there can be no doubt about its effectiveness. The experiments of Cohlan have been confirmed in our laboratory and have been extended by Giroud and Martinet[19] who studied the time factors involved and the anatomic details of some of the malformations.

Most of the work mentioned here was done with rats of commercial stocks or with rats bred and reared for many years in scientific institutions. The experiments were usually well controlled, and the incidence of spontaneous congenital malformations was low in such stocks. As a rule, the results of the various teratogenic agents were the same, irrespective of the origin of the rats; however, minor discrepancies in different laboratories were sometimes attributed to "strain" differences. Genetic studies were not made in these rat experiments.

Genetic Factors

A few nutritional studies were done with inbred strains of mice to investigate the differential susceptibility of genetically differing strains of mice to the same teratogenic agent. By using genetically standardized animals, it is also possible to demonstrate the effects of nutritional deficiencies upon embryonic morphogenesis. Kalter and I[20] examined the congenital malformations induced in inbred strains of mice by feeding diets deficient in riboflavin to which galactoflavin had been added. The teratogenic diets successfully used by Nelson and others[12] in rats had to be modified, since the mice did not reproduce under the dietary conditions that were effective in rats. A large variety of malformations was obtained in the young mice when the diets were fed to the mother from the 10th to the 14th days of gestation. The mice used were of the highly inbred A/Jax, DBA, 129, and $C_{57}BL$ strains. Skeletal anomalies could be detected by gross inspection or by clearing of the specimens, and soft-tissue anomalies were found in histological sections. Some of the malformations produced in these mice resembled those produced by the same method in rats; however, there were differences in the two species, and there were differences in the malformations in the offspring of the four strains of mice. Atresia of the esophagus, for instance, was induced by this method in about 80% of the young of strains A/Jax and DBA but in only 2% of the $C_{57}BL$ offspring. The pattern of malformations presented by each strain of mice was more or less specific.

An interesting observation was made by Runner and Miller[21] in the young of mice of strain 129. When females of that strain were fasted for 24 hours during the ninth day of pregnancy, exencephaly, vertebral anomalies, and fused ribs were induced in 28% of the fetuses. It is noteworthy that, in the presence of a certain genetic constitution, temporary maternal starvation, a rather unspecific nutritional deficiency, can result in congenital malformations of the young.

In addition to these studies, other investigations have been conducted in this field. For a more complete orientation, the reader is referred to other extensive reviews in the literature.[22]

Interpretation of Experiments

A few remarks about the interpretation of the experiments cited may be in order. It should be stated at the outset that the experiments do not prove that congenital malformations in man are due to maternal dietary deficiencies. Those acquainted with the details of the experimental nutritional methods resulting in congenital malformations appreciate the differences between the experimental conditions employed and the conditions of human reproduction. When we speak of a dietary deficiency as a cause of malformations in experimental animals, we usually mention only one of the factors involved in the production of the congenital malformations. To make the experiment successful, that is, to create a borderline deficiency injurious but not lethal to the embryos, the depletion time must be regulated according to the mother's ability to store and restore the particular nutritional factor. Sometimes the depletion must be terminated prematurely at a certain period of gestation by administration of a supplement to avoid complete destruction of the damaged fetus; some depletion methods require administration of inhibitors or antimetabolites. The outcome of the experiment also depends upon the genetic make-up of the animal species or strain selected for the experiment.

The fact that a teratogenic method produces a certain malformation in rats does not permit the conclusion that it will be equally effective in mice. How much more hazardous is it then to equate such animal experiments with human conditions. However, in certain cases adverse nutritional conditions of the mother may impair the development of human fetuses; for example, endemic cretinism has been attributed to maternal iodine deficiency. Although the etiology of endemic goiter[23] and cretinism is complex, these conditions disappear when iodized salt or improved diets are introduced into the endemic areas.[24] Antimetabolites that are teratogenic in animals may also be teratogenic in man.[16] The fact that starvation in early pregnancy can cause malformations in the young of some inbred strains of mice[21] cannot be ignored, since anorexia, vomiting, or lack of food could, in rare instances, cause comparable situations in women. It should be emphasized that, to date, the teratogenic effect of starvation has been demonstrated only in the presence of certain maternal attributes and that it may depend to a great extent upon the genetic constitution of the mother and the embryo.

Although the experiments cited may not be of practical importance at this time, they have influenced many theories concerned with congenital malformations. The early investigators who worked in nutritional teratology were searching for an experimental method to produce congenital malformations in mammals. They succeeded in demonstrating that adverse environmental conditions must be considered as possible causes of prenatal deformities and that these conditions could be of a rather subtle nature.

In recent years other teratogenic methods have been developed which supplement early nutritional studies. Some of these methods require less skill and effort than the nutritional studies and are, therefore, preferable for certain teratological investigations. However, the nutritional studies mentioned point to the importance of well-defined chemical compounds whose role in prenatal development had not been recognized before. Some of these substances are known to be constituents of enzyme systems which may be rendered ineffective by the lack of such nutritional elements. Since it is generally assumed that genetic mechanisms are mediated through enzymatic activity, I should like to express the hope that nutritional teratology will eventually benefit genetic investigations concerned with the mode of action of abnormal genes. It is possible that both genic "deficiencies" and certain prenatal nutritional deficiencies result in aberrations of similar enzymatic processes necessary for normal development.[25] In the field of teratology there is common ground for the developmental geneticist and the nutritionist. In this area teratogenic nutritional experiments may eventually make their greatest contribution to the science of teratology.

Summary

Many methods are now available that permit production of congenital malformations in mammals, and among these are nutritional experiments that have been widely used as instruments of teratological research. Congenital defects of the central nervous system, of the eyes, of the skeleton, and of the cardiovascular, urogenital, and other systems have been produced under strict experimental conditions. In the application of such animal experiments to questions of congenital malformations in man, great caution must be exercised, since the animals are subjected to artificial environmental conditions which are not likely to occur in human beings.

This study was supported by grants from the National Institute of Arthritis and Metabolic Diseases, U. S. Public Health Service, and the National Vitamin Foundation, Inc.

TEN YEARS OF SPACE MEDICINE

CIVILIAN and military scientists are cooperating extensively to devise a vehicle in which man may be safely lifted into outer space, perhaps as far as the moon or some planet. A project so immensely complex and far reaching requires the knowledge and skills of many groups of scientists—astronomers, physicists, chemists, biologists, engineers, botanists, metallurgists, psychologists, physicians, and others. Already the engineering capability exists to launch rocket vehicles at orbital or escape velocities; however, the techniques devised to keep the human astronaut healthy, to rescue him in case of disaster, and to bring him back safely to earth are in need of many refinements. To this end, the U. S. Air Force School of Aviation Medicine, nearly 10 years ago, founded a department of space medicine which was the first branch of any educational or research institution concerning itself solely with conditions that man would meet in space. The research accomplished by this school serves today as the foundation of all planning in the United States and abroad for man's venture into space.

To review the accomplishments and discuss the unsolved problems, the school with the assistance of the Southwest Research Institute convened an international symposium on space medicine a few days ago at San Antonio, Texas. In this assembly of more than 600 scientists, confidence prevailed in ultimate success. However, extremely difficult problems stand in the way.

Long-time manned space flight in a sealed cabin demands, without prohibitive weight, the provision of food, the disposal of excreta, and the gas exchange requirements. As an approach to these problems, Prof. Jack Myers of the University of Texas has investigated the possibility of using oxygen-producing algae. A photosynthetic gas-recycling system would provide oxygen produced by the algae for the man to breathe and the algae would complete the gas-exchange cycle by growing on the carbon dioxide exhaled by the man. The algae would also manufacture food materials necessary for the sealed-in space navigator. Dr. Myers reported an experiment in which he used mice and the green alga Chlorella which operated satisfactorily for one month and could have been continued longer. He has emphasized that, while no use of this procedure is reasonably foreseen in the immediate future, the experiment provides a demonstration of operation of a photosynthetic gas exchanger and should contribute to a long range kind of operation.

In a panel on space problems presented by the Association of Military Surgeons of the United States in Washington, D. C., in November, Finkelstein and Taylor, reporting from the Wright-Patterson Air Force Base, said that a practical means to regenerate the carbon and nitrogen compounds man needs will remove all food limitations to the duration of space flight. The technical feasibility of such regenerative cycling is not in question and research in the strict sense of the word is not required. Technical development and applied research however, are needed. Work is under way to find a more efficient form of algae and there has been considerable speculation about the possibility of algae as a source of food.

Kitzes, of the Wright Air Development Center said that eventually closed ecological systems will be available to provide complete regeneration and reclamation of all gaseous, liquid, and solid materials needed in normal human metabolism. Champlin of the Army Ordnance Missile Command, noted before the panel in Washington that many volunteers for space flight have already declared themselves. Volunteers obviously should meet various special physical and mental requirements. Actually, it was stated, certain physical handicaps may be an advantage in space flight.

Many of the other problems discussed at San Antonio, which the School of Aviation Medicine is trying to solve, involved advanced training in areas far removed from the present-day knowledge of most practicing physicians.

Prof. Hubertus Strughold, often referred to as the father of space medicine, in reviewing the 10 years that have elapsed since the first scientific meeting was held on the medical problems of space flight, said at the San Antonio meeting: "We have complete knowledge about certain factors in space flight; about others we have some knowledge, and about the rest we depend entirely on extrapolations or even on speculations." And yet he is confident that research will find the answer to many of the unsolved problems. "There is no question," he said, "that Mars and Venus, besides the Moon, will be targets of manned space operations within this century."

BUREAU OF MEDICAL ECONOMIC RESEARCH

A BOOK ON MEDICAL CARE

Vaughn D. Bornet, Ph.D.

The five specialists in the field of public health who extracted and assembled the material for the book "Readings in Medical Care"[1] express the hope that their book will contribute to "sound and realistic solutions of medical care questions of the future by making knowledge about past and present problems more conveniently accessible." They tried, they say, "to choose the most useful and informative writings available and to include items representing differing points of view on controversial questions." "Readings in Medical Care" is the creation of Drs. Solomon J. Axelrod (University of Michigan School of Public Health), Franz Goldmann (Harvard University School of Public Health), Milton Terris (University of Buffalo School of Medicine), Jonas N. Muller (New York Medical College), and Cecil G. Sheps (Beth Israel Hospital), assisted on editorial matters by Edward B. Kovar. It is specifically stated in the Preface that the Association of Teachers of Preventive Medicine took "no active part" in determining content. The Committee on Medical Care Teaching, for its part, merely "advised the editors on the scope and general orientation of the volume, but not on the choice of specific material for inclusion."

The Problem of Selection

A certain directional aspect is placed on the book in the Foreword by Dr. George Packer Berry, dean of the faculty of medicine at Harvard University, who observes that rapid changes in society and medical science mean that "the framework and content of medical care and health service will inevitably have to change." And he judges that the present volume is in fact "a balanced and representative collection." In the light of these several statements of hope and appraisal the task of the reviewer is clearly outlined in advance. Does the book realize these aspirations? Does it justify these judgments?

At the outset, one must observe that a book of readings destined for use by students of medical care organization shares some of the responsibilities inescapable in compilations of this character commonly seen in our universities. Such books of readings are basically a substitute for the original publications. No longer need students who own such a book browse in the library stacks, explore reserve book shelves, or search out old magazines in periodical rooms. The card catalog, guides to periodical literature, and library reference personnel have been bypassed. The open market place, where published materials and ideas find their level, is closed in a sense by all who select and reprint under one cover what they consider to be the important materials of the field. To assemble, extract, arrange, and properly introduce a tiny portion of the total literature of a technical area of scholarship and affairs to the end that teachers will be able to present students with a reliable and realistic portrait in miniature is to shoulder a heavy load. The burden of the reviewer is only a little lighter, for he must try to make clear the apparent extent of the over-all accomplishment.

Analysis of "Readings in Medical Care" may properly begin with the 122 selections incorporated in its 13 parts, for there are only 15 pages of original material out of 694 pages. There are few explanatory footnotes, and it was a questionable editorial decision to eliminate almost all footnotes from the original items. These key decisions will certainly be severely questioned by teachers who choose to adopt the book for student use. Extracts from diversified secondary sources seldom, if ever, speak clearly to the uninitiated without at least some editorial interpretation. Even if the one-page essays which introduce each of the 13 parts of the book had been uniform in quality, they would be no substitute for the road map these learned editors did not bother to provide. One assumes that they were thoroughly familiar with many pertinent details about the cited authors and organizations; the circumstances of original publication were normally known to them; but they passed on to the student none of this highly relevant lore. In some classrooms, therefore, "Readings in Medical Care" may raise more questions for the teacher than it solves.

Topics and Space

The editors view the problem of illuminating the subject of "medical care" chiefly in terms of physicians, hospitals, government, insurance, and the public. They give little space to dentistry and virtually none to the pharmaceutical industry or to the significance of its products. More than three-quarters of a 106-page section on The Medical Care Team is given to physicians. Dentists, medical social workers, technicians, and nurses share what is left. Does this decision on emphasis best meet the needs of medical students and young people in

---

Research Associate, Bureau of Medical Economic Research, American Medical Association.

graduate schools of public health? One may well doubt it. Over-all, the editors divided their space as is shown in the table.

In examining this table it should be borne in mind that the Selections are the excerpts actually comprising the present book, while the "Further Readings" are the lists given at the close of each part; a title appears in one or the other, but not both. Many of the selections come from the same printed source ("Medical Care for Americans," a 1951 publication, provided five selections; "Building America's Health," the product of the President's Commission on the Health Needs of the Nation, 1952-1953, furnished six). Yet each book or article was listed at the close of no more than 1 of the 13 parts. No reasonable reason for this peculiar decision comes to mind. Certainly to list such comprehensive books as "Financing Hospital Care in the United States" (3 volumes) only at the close of the section on insurance and not at all in the section on hospitals (a typical and necessary consequence of such a decision) makes the bibliographical lists strangely lopsided. "Paying for Medical Care in the United States," by Oscar N. Serbein Jr., a compendium with 237 tables, is listed only once, even though its contents (like a great many others of the 177 "Further Readings") are related to fully half a dozen of the sections of the book under review here. Before leaving the subject of bibliographical references, it must be said that little effort was made to cite important articles in periodicals, even though the periodical and pamphlet literature on medical care is extensive and rich. The bibliography in Serbein's 1953 book, for example, lists 25 items by the Bureau of Medical Economic Research of the American Medical Association, but the present book (1958) lists only 9; Serbein lists 11 items by Selwyn D. Collins, while the present volume mentions only 3. Other examples could be given, each illustrating the point.

Division of Space in "Readings in Medical Care"

Part	Title	No. of Pages (1)	No. of Selections (2)	No. of "Further Readings" (3)
I.	Problems in Medical Care: the General Background	29	5	9
II.	The National Health Picture	45	10	16
III.	Adequacy of Medical Care	40	9	3
IV.	The Costs of Medical Care	34	9	10
V.	The Medical Care Team	166	15	18
VI	Hospitals	75	10	12
VII.	Coordination in Health and Medical Service	44	10	11
VIII	Care of Long-Term Illness	48	9	13
IX.	Rural Medical Care	24	6	7
X.	Public Medical Care	49	5	27
XI.	Medical Care in Industry	60	11	20
XII.	Medical Care Insurance	110	16	21
XIII.	Principles and Proposals	30	7	10
	Totals	694	122	177

Referring back to the table above, the decisions made on division of space by subject come under review. Medical Care Insurance and The Medical Care Team are the longest of the parts; Rural Medical Care, Principles and Proposals, Problems in Medical Care, and The Costs of Medical Care are the shortest. Authorities will no doubt disagree on the space that might have been given to each of these subjects.

When Is Contemporary?

Bearing in mind the objectives stated by the editors, one is surprised at the age of many of the readings excerpted in "Readings in Medical Care." Their average (mean) and median year of publication is 1949. The section (part) on the adequacy of medical care consists of selections published in 1932-1933, 1947, 1949, and 1954. When is contemporary? Of the 122 extracts, 8 were originally published in 1931-1940, 67 in 1941-1950, and 47 in more recent years; only two extracts in this 1958 publication date from later than 1955. What are we to think as we survey this situation? It may be that some of the writings chosen have not been replaced; for example, the studies of the Bureau of Medical Economic Research of the American Medical Association on the distribution of physicians are the latest. It is a service, furthermore, to remind students of old controversies and of the extreme positions taken by some during the decade after World War II. Yet difficulties arise from the decision of the editors to print so many materials which do not portray accurately the medical care realities of the post-Korean years. The median year of all publications mentioned in the bibliographical lists is four years later (1953 versus 1949) than that of the extracts chosen for reprinting by the editors.

Free Choice and Fee-for-Service

Remembering the several assertions of the editors regarding their self-imposed goal of giving students items representing differing points of view and of communicating to them knowledge about past and present problems in the socioeconomic field of medical care, the present reviewer tested the book on several important matters. First, the principle of free choice of physician is singularly ignored in this book. The selection from a 1945 book of Dr. Franz Goldmann mentions the existence of a "vast literature" in favor of free choice (page 347). That is true. But the five experts who shared responsibility for these pages (including Dr. Goldmann) did not see fit to include a single item devoted to the defense of free choice. The only index reference is to unsympathetic comments by the latter. Is free choice of physician unrelated to the past, present, and future of medical care?

A second subject tested by the reviewer was "fee-for-service" as a form of paying for medical care. There are three short treatments of the matter. In a quoted 1952 statement, Dr. Goldmann curtly conveys its alleged advantages in three brief sentences and then attempts to tear it apart in half a page of earnest prose (page 194). A second mention is in a 1946 congressional committee report; there, the extra paperwork supposedly accompanying fee-for-service is stated to be an important defect of that method of payment. In a third reference (page 660) Dr. Ernst P. Boas judges in his 1945 publication of the Society for Ethical Culture that "Insurance guaranteeing complete medical coverage cannot be set up, except at a prohibitive cost, if the fee-for-service principle is retained." It forces on health insurance, moreover, "a complicated and expensive system of checks to detect cheating." One may safely conclude that fee-for-service was not considered particularly worthy of student consideration by those who compiled the present book.

Since the word "ethics" does not appear in the Index, "Hippocratic Oath" was checked through the book as a substitute. It, too, was deemphasized to the point of extinction. Dr. Goldmann informs his young readers on page 199 that "If the physician lives up to professional ideals and strictly observes the code of ethics embodied in the Hippocratic oath he may well conclude his days in poverty. If he acts like a businessman he can acquire a big bank account and a large estate within a few years but will furnish ample ammunition for complaints about commercialism in the system of private practice. A well organized and efficiently administered system of paying physicians for service in medical care programs can markedly reduce the dilemma confronting the possessor of the most humane of arts" (1952). Finally, as a preliminary to an attack on free choice of physician, Wendell Berge, an attorney, is quoted as saying in 1945, "Let us briefly survey the great trends which converge upon medicine, for they decree a revision of means if the great ends of the Hippocratic Oath are to be served" (page 668). Among other rays of light directed on medical practice by this "expert" in a 10-page extract are these: "To me it seems that one of the great shortcomings of the prevailing medical system is that the practitioner is kept so busy with his patients that he cannot translate his work into medical discovery" (page 676). And, "If there is one field where freedom of choice should be qualified, it is medicine" (page 671). For him, "A new medical order is inevitable." Why were his views in the section on Principles and Proposals (the book's conclusion) given a third of the space while the American Medical Association and American Dental Association share only three pages?

Returning to the time element as presented in "Readings in Medical Care," one notes the heavy concentration on the years of the first Truman Administration. Fifty-one of the quoted materials derive from that era. Opinions will differ sharply on the wisdom of including so many of these materials, especially on including them without some clearcut method of indicating how deceiving is the repeated use of the words "now" and "at the present time" and their equivalents. Certainly it is no service to students to hand them without comment such dogmatic evaluations as that of Dr. Boas (1945), "For all these reasons, protection offered by voluntary sickness insurance in this country is minute in comparison to the need." Furthermore, "National compulsory health insurance is the only practical method of spreading the benefits of good medical care to the whole population" (pages 660, 661). In any event, the coverage of voluntary health insurance in this book is hopelessly out of date and decidedly misleading.

Selected Selections

In concluding their pioneering volume, one which performs a useful bibliographical service by reminding us of the variety of the literature published on medical care during the past quarter century, the editors write (page 666), "Hopefully, the background of information and the stimulation of the ideas presented in these pages will help us to select the more meaningful of these many proposals [on the organization and financing of medical care], to evaluate them intelligently, and to act upon them as mature and understanding citizens." In the opinion of the reviewer, however, this hope of intelligent evaluation and appropriate action based on study of the present book has a chance of being realized only in the case of readers who lived through the era when these proposals were popularized and who are thoroughly conversant with present trends in the medical care field. For it must be said that "Readings in Medical Care" does not present the alternatives on many major matters in the medical care field with equal skill or enthusiasm. Students will certainly need many additional reading assignments from the past and the present if they are to arrive at reasonably balanced judgments.

MEDICAL NEWS

ALABAMA

Grant for New Psychiatric Clinic.—Announcement was made recently of a federal fund grant of $196,187 for a new psychiatric clinic at the University of Alabama Medical Center. Located at University Hospital, it is the first unit of a proposed new ambulant patient center. Designed to handle an estimated 25,000 patients a year as well as for expanded research and teaching purposes, the clinic is a self-financing operation, since no community funds are available for the hospital's vast indigent out-patient service. The present psychiatric clinic is located in offices on the second floor of a store at the Medical Center. The new clinic will be constructed in the block chosen for the proposed out-patient center, bounded by Sixth and Seventh Avenues and 17th and 18th Streets, south, Birmingham.

CALIFORNIA

Dr. Newell Honored.—The Gold Medal of the Radiological Society of North America was presented Nov. 20 to Dr. Robert R. Newell, San Francisco, during the 44th annual meeting of the society in Chicago. Dr. Newell is emeritus professor of medicine (radiology) Stanford University Medical School and Scientific consultant to U. S. Naval Radiological Defense Laboratory, San Francisco. He was president of the American College of Radiology in 1951 and received the college's Gold Medal in 1957. He is currently a member of the National Committee on Radiation Protection.

Provost Appointed.—The appointment of Dr. John B. deC. M. Saunders as provost of the University of California Medical Center, San Francisco, and Willard C. Fleming, D.D.S., as vice-provost has been announced by President Clark Kerr, of the statewide university. Dr. Saunders will continue as dean of the School of Medicine and Dr. Fleming as dean of the College of Dentistry. In his new position as provost Dr. Saunders will be the responsible administrative chief of the Medical Center and Dr. Fleming will be his deputy. Dr. Saunders has exercised many of the duties of provost since he became dean of the School of Medicine in February, 1956.

Symposium on Aviation Medicine.—The present and future problems of space flight, small aircrafts, jet transportation, and flying safety were the major discussion topics at the fourth annual Symposium in Aviation Medicine, held Oct. 22-24 in Santa Monica, sponsored by the University of California School of Medicine and University of California Extension, Los Angeles. Dr. Coleman M. Whitlock, Jr., head of Human Factors, Space and Radiation Medicine of Convair Astronautics, San Diego, spoke on "Omnienvironmental Testing as Applied to Space Flight." Col. Harry G. Moseley, chief of the Aero Medical Safety Division, Directorate of Flight Safety Research, Norton Air Force Base, Calif., presented "Military Developments in Flying Safety." Mr. Al Blackburn, president of the Society of Experimental Test Pilots, discussed improved federal regulations to decrease aircraft collisions. On the last day of the meeting, "Man in the Space Environment" was discussed by Capt. Julian E. Ward, director of the Bioastronautics Group at the Inglewood, Calif., Air Force Ballistic Missile Division.

COLORADO

Large Grant for Research Facilities.—The U. S. Public Health Service has notified Dean Robert J. Glaser, of the University of Colorado School of Medicine, Denver, that it has approved a grant of $1,344,165 in matching funds for construction of research facilities at the Colorado University Medical Center. The funds are made available for new construction and remodeling in the center's long-range building program, and up to $140,665 of the matching grant may be used for equipment. The Medical Center's proposed $17,500,000 expansion program includes a new 405-bed hospital, medical and dental research facilities, outpatient clinics, and other construction north of the present campus. The federal funds are not for a specific building.

DISTRICT OF COLUMBIA

Dr. Habel Consults on Rabies in Latin America.—Dr. Karl Habel, research scientist of the National Institutes of Health, left Oct. 11 for six weeks of consultation with five Latin American governments. Officials of the Pan American Sanitary Bureau, Regional Office for the Americas of the World Health Organization, said Dr. Habel served as a consultant on rabies and other virus problems. As a staff member of the bureau's Pan American Zoonoses Center he visited Brazil, Argentina, Chile,

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

Peru, and Panama. Dr. Habel is a member of the WHO Expert Committee on Rabies and the originator of the Habel test for virus potency. At the Zoonoses Center, in Azul, Argentina, he helped with work being done in the virus laboratory. As recently as 1956, the year of the center's founding, there were 149 reported deaths in the hemisphere due to rabies. Every country of the Americas, save one, is said to have a rabies problem. The lone exception is Uruguay, where a successful eradication campaign was completed some 15 years ago.

ILLINOIS

Chicago

Medical History Meeting.—The Society of Medical History of Chicago will meet at the Institute of Medicine (fourth floor, 86 E. Randolph St.) Dec. 17, 8:00 p. m. This is an open meeting; all are welcome. Dr. Helmut P. G. Seckel, associate professor, department of pediatrics, University of Chicago, will present "The Vienna School of Pediatrics and the Concept of Allergy," after which Dr. E. Lee Strohl, associate professor of surgery, Northwestern University Medical School, will speak on "Ladies of Lynn—Emphasis on One."

Chicago Medical School Anniversary.—The Chicago Medical School marked the 10 years of its accreditation and approval "as a medical college of high standing" Nov. 25 at a dinner meeting in the Standard Club. The story, narrated by Alex Dreier, news commentator, concerned the early history of the school up to its approval on Nov. 9, 1948, by the American Medical Association and the Association of American Medical Colleges. Dr. John J. Sheinin, president of the school, described the future plans. A new research institute, the first of seven buildings to be erected on the 10 acres of ground in the West Side Medical Center, is in the planning stage and construction is expected to begin in spring.

Personal.—Dr. James E. Cassidy was named assistant director and chief of the medical unit of the Student Health Service of the University of Chicago, effective August 1.——Aaron Novick, Ph.D., who has been a member of the University of Chicago faculty for 11 years, has been named director of the Institute of Molecular Biology at the University of Oregon, Portland, effective Jan. 1.——University of Chicago faculty and friends of Dr. Paul C. Hodges, professor emeritus of radiology at the University of Chicago, held a dinner in his honor Nov. 6. He joined the faculty as one of the original members of the University Clinics staff and was appointed chairman of the department of radiology in 1927. He retired June 30, 1958. Scheduled speakers at the dinner were Chancellor Lawrence A. Kimpton, Ph.D.; Dr. Lowell T. Coggeshall, dean of the Division of Biological Sciences; and Dr. Franklin C. McLean, professor emeritus of physiology.

Founders Day Awards.—Dr. Richard H. Young, Northwestern University Medical School dean, presented awards to six medical school students and graduates Sept. 30 at a Founders Day convocation. The convocation honored the founders of the medical school and formally opened the school's 101st annual session. The Founders Day address was delivered by Dr. Guy P. Youmans, chairman, department of microbiology, who spoke on "The Other World." Dr. Robert C. Larlett, Tucson, Ariz., received the Borden undergraduate research award in medicine, $500 and a certificate, "given to a student in the graduating class who performed meritorious medical research while an undergraduate medical student." Winner of the George J. Dennis Phi Rho Sigma award was Harry L. Gibson, of Springfield, Mo., who received a $100 bond for maintaining the highest scholastic average during the first three years of medical school. Robert Lynn Parker, Box 6, Hollansburg, Ohio, was the recipient of the Phi Beta Pi–Leslie B. Arey award, "given to the freshman student for the highest scholastic achievement in the study of anatomy." The $50 award has been named in honor of Dr. Leslie B. Arey, professor emeritus of anatomy. Winner of the Roche award, given by Hoffman–LaRoche Inc., "for outstanding scholastic attainment during the sophomore year," was Albert D. Newcomer, Dixon, Ill. Mr. Newcomer was given a scroll and an engraved watch.

LOUISIANA

Lectureship in Social Psychiatry.—Tulane University, New Orleans, has announced the creation of a lectureship in social psychiatry jointly sponsored by the department of psychiatry and neurology and the department of sociology and anthropology and supported by the Mona Bronfman Sheckman Foundation. Dr. John P. Spiegel, the first speaker in this annual series of lectures, discussed "The Structure and Function of Social Rules in the Doctor-Patient Relationship" Oct. 23 through 25. The guest lecturers will be alternately a social scientist and a psychiatrist. The lectures will be published in monograph series. (For information contact the program co-chairmen, Dr. Harold I. Lief or Prof. Forrest E. LaViolette, Ph.D., Tulane University.)

MARYLAND

Visiting Lecturer.—Prof. Curt Stern, Ph.D., of the University of California, Berkeley, will be visiting lecturer in medicine at the Johns Hopkins Hospital, Baltimore, during the month of January, 1959. During this time he will give a series of 12 lectures entitled "A Survey of Human Genetics."

MASSACHUSETTS

Mueller Memorial Lecture.—Joshua Lederberg, Ph.D., one of three American scientists to share the 1958 Nobel prize in medicine and physiology, delivered the second annual J. Howard Mueller Memorial Lecture at the Harvard Medical School, Boston, Nov. 13 on "Genes and Antibodies: Genetic Models of Immunity and Differentiation." The lecture honors Dr. Mueller who at the time of his death in 1954 was Charles Wilder Professor of Bacteriology and Immunology at Harvard. W. E. Van Heyningen, of Oxford University, England, delivered the first Mueller Memorial Lecture in April, 1958.

Seminar on Medical Education.—The department of medical education at Beverly Hospital, Beverly, has announced a Seminar on Medical Education for the non-university hospitals of New England to be held Jan. 9-10 with Drs. Alexander M. Burgess, Providence, R. I., and John C. Leonard, Hartford, Conn., as co-chairmen. A symposium, "Considerations in the Maintenance of an Effective Teaching Program in the Non-University Hospital," will be moderated by Dr. Leonard, 3:15 p. m., Jan. 9. Other topics and participants are as follows:

Aims and Objectives of the American Association of Directors of Medical Education, Dr. William J. Lahey, Hartford, Conn.
The Community Teaching Hospital in Graduate Medical Education, Dr. Jean A. Curran, Boston.
Report from the Educational Council for Foreign Medical Graduates, Dr. Dean F. Smiley, Evanston, Ill.
The Future of the Non-University Hospitals in New England, Dr. John C. Nunemaker, Washington, D. C.

For information write Dr. Philip D. Herrick, Director of Medical Education, Beverly Hospital, Beverly, Mass.

MICHIGAN

Births Decline.—During the first eight months of this year 2,436 fewer babies were born in Michigan than during the comparable period of 1957, the Michigan Department of Health reports. Birth registrations during the initial two-thirds of 1958 totaled 129,172, as against 131,608 in the first eight months of last year. Births for 1958 exceeded 1957 monthly totals for the first five months of this year, but June, July, and August births totaled 891, 1,145, and 787 under the same months of last year. State health department records show that in 1957 births ran behind the previous year for the first four months but then rallied sharply and set an all-time 12-month record of 207,308.

NEW JERSEY

Aging Division and Senior Center Established.—As a result of a study of its 150-member citizens committee, the Bergen County Tuberculosis and Health Association of New Jersey has established a Division of the Aging and opened a Senior Center, which will offer both an activity program and a specialized guidance and referral service. The division will plan additional projects and work to stimulate public interest and activity in further aspects of aging, such as preparation for retirement, housing, facilities for the chronically ill, etc. For information, write to the association at 369 Union St., Hackensack, N. J.

NEW YORK

Dr. Moe Honored.—Dr. Gordon K. Moe, chairman, department of physiology, State University Upstate Medical Center in Syracuse, received the University of Minnesota's outstanding achievement award Sept. 29. The award was given at the university's Medical Foundation Day exercises. Dr. Moe has been chairman of the physiology department of the Upstate Medical Center since 1950. He previously was on the faculties of Harvard Medical School and the University of Michigan Medical School, Ann Arbor. Dr. Moe received a traveling fellowship from the American Physiology Society for study at Oxford in 1947, and was a visiting scientist at Sandoz Laboratories, Basel, Switzerland, in 1949. In 1951 he served on a medical teaching mission of the Unitarian Service Committee and World Health Organization to Israel and Iran.

New York City

Bronx Hospital Expands Facilities.—A $350,000 project involving the installation of a postoperative recovery unit and expansion of the operating theater and the x-ray department has been completed by the Bronx Hospital, Dr. Aaron A. Karan, hospital director, has announced. The remodeled, air-conditioned, and expanded operating theater will facilitate the surgical management of the increase in the number of formidable procedures performed at the hospital. In 1957 more than 5,500 operations were performed at the hospital.

Eightieth Birthday Celebration.—A meeting sponsored by the Association for the Advancement of Psychoanalysis in honor of Dr. Kurt Goldstein's 80th birthday was held at the New York Academy of Medicine, Oct. 22. Speakers at the meeting were: Dr. Harold Kelman, speaking on "Kurt Goldstein's Influence on Psychoanalytic Thought"; Dr. Lawrence S. Kubie, on "A Reexamination of the Concepts of Conscious, Preconscious and Unconscious Functions"; Rollo R. May, Ph.D., on "Kurt Goldstein and Concepts of Creativity," and Dr. Frederick A. Weiss, on "Kurt Goldstein and His Concept of Human Nature."

Advisory Board for Institute of Nutrition.—Former President Herbert Hoover has accepted the post of honorary chairman of the new advisory board of the Institute of Nutrition Sciences at Columbia University. Mr. Hoover opened the first meeting of the advisory board Oct. 1. The meeting of the board marks the activation of plans for the Institute of

Nutrition Sciences, for which arrangements have been completed and which was created at Columbia to meet the need for properly trained experts to combat problems of nutrition. The plans include cooperative activity with institutions in foreign countries. Institute headquarters are at Columbia-Presbyterian Medical Center, in the School of Public Health. The facilities of Columbia's graduate schools and institutes have been made available for teaching and research.

OREGON

Dr. Dunphy Appointed Surgical Department Chairman.—Dr. John E. Dunphy has been appointed professor and chairman of the department of surgery at the University of Oregon Medical School, Portland. He will take up his new duties after the first of the new year. Currently professor of surgery at Harvard Medical School, Boston, Dr. Dunphy also is director of the Harvard Surgical Service and the Sears Laboratory at Boston City Hospital. He will assume the position vacated a year ago by Dr. William K. Livingston, who retired to a part-time position in surgery after serving as professor and departmental chairman for more than a decade. Named professor of surgery at Harvard in 1955, Dr. Dunphy serves on the editorial boards of the *New England Journal of Medicine*, the *Annals of Surgery*, and the *American Journal of Surgery*.

PENNSYLVANIA

Meeting on Rehabilitation.—The Pennsylvania Academy of Physical Medicine and Rehabilitation will meet at the Harrisburg Hospital, Harrisburg, at 1:00 p. m., Jan. 17. The program will be as follows:

Management of Low Back Problems, Dr. George A. Berkheimer, chief of the orthopedic department of Harrisburg Hospital.
Management of the Paraplegic, Dr. Robert L. Harding, head, department of plastic surgery.
Rehabilitation of the Lower Extremity Amputee, Dr. Allen S. Russek, director, Physical Medicine and Rehabilitation Hospital for Joint Diseases, New York City.
Management of Cervical Problems, Dr. Nathan Sussman, chief Arthritis Clinic and head department of physical medicine and rehabilitation of the Harrisburg Hospital.
Physical Treatment of Shoulder Lesions, Dr. William H. Schmidt, head department of physical medicine and rehabilitation, Jefferson Medical College, Philadelphia.

For information write Dr. Joseph M. Johnston, Secretary-Treasurer, Pennsylvania Academy of Physical Medicine and Rehabilitation, 694 Washington Road, Pittsburgh 28.

Philadelphia

Dr. Ravdin Receives Lovelace Award.—Dr. Isidor S. Ravdin, vice-president for medical development, University of Pennsylvania, and John Rhea Barton professor of surgery, was named to receive the first annual Lovelace Foundation award in a ceremony in Albuquerque, N. M., Nov. 18. According to Dr. Burgess L. Gordon, executive secretary of the foundation, and formerly president of Women's Medical College in Philadelphia, the award will go each year to the nation's "most outstanding medical figure" as selected by the foundation's board of directors.

PUERTO RICO

Physicians Meeting in Santurce.—The American College of Physicians eighth regional meeting will be held Dec. 19-20 at the Puerto Rico Medical Association Building, Santurce, Puerto Rico. Presiding at the opening sessions will be Dr. F. Hernandez-Morales, governor of the college for Puerto Rico. Of the 17 papers scheduled, the following will be included in the first session: "Recent Developments in the Diagnosis of Hyperparathyroidism" and "Angina Pectoris and Its Gastrointestinal Interrelationships," by Major Milton E. Rubini, M. C., U. S. Army and Dr. Henry L. Bockus, Philadelphia, respectively. Guest speaker and official representative of the college at the noon luncheon, Dec. 20, will be Dr. Robert Wilson, Charleston, S. C., regent of the college. For information write the American College of Physicians, 4200 Pine St., Philadelphia 4.

WEST VIRGINIA

Dr. Laird Receives Surgeons' Award.—Dr. William R. Laird, of Montgomery, received the Distinguished Service Award of the American College of Surgeons during the annual meeting of the clinical congress in Chicago, Oct. 6-10. Dr. Laird has served as West Virginia governor of the American College of Surgeons, and is a diplomate of the American Board of Surgery. He is currently chairman of the visiting committee of West Virginia University School of Medicine, Morgantown. Dr. Laird is also president of the board of trustees of the Laird Foundation, a director of Education Foundation, Inc., and trustee of the Daywood Art Gallery in Lewisburg.

Personal.—Dr. Margaret T. Ross, of Beckley, has been appointed director of the Division of Community Services of the State Department of Mental Health. Dr. Ross has been serving as chief of psychiatry at Beckley Memorial Hospital since it opened in December, 1955.——Dr. John W. Lane, of Middletown, Conn., has been named acting superintendent of the Spencer State Hospital, Spencer, to succeed Dr. Isaac C. East, who has accepted appointment as staff psychiatrist at the Mississippi State Hospital at Whitfield.——At the annual meeting of the West Virginia Heart Association, Oct. 10, Dr. James H. Wolverton Jr., of Piedmont, was elected president and Dr. Jesse J. Jenkins Jr., of Fairmont, president-elect.

GENERAL

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories and possessions in the weeks ended as indicated:

Area	Nov. 15, 1958		Nov. 16, 1957

Fellowships for Research in Blindness.—The National Council to Combat Blindness, Inc., has announced that it is now accepting applications for its 1959-1960 Fight For Sight grants-in-aid, research fellowships and summer (1959) student fellowships. The closing date for receipt of completed applications for grants and fellowships has been advanced to March 1, 1959, in order to allow time for processing and review. Applications for summer student fellowships will be reviewed in advance of the June meeting of the Scientific Advisory Committee. Appropriate forms may be obtained by addressing: Secretary, National Council to Combat Blindness, Inc., 41 W. 57th St., New York 19. Fight For Sight grants-in-aid and full-time research fellowships are generally awarded for a period of one year and may be extended for an additional period with the approval of the National Council to Combat Blindness' Scientific Advisory Committee, chaired by Dr. Charles A. Perera, associate clinical professor of ophthalmology, College of Physicians and Surgeons, Columbia University, New York City. The Scientific Advisory Committee, which votes on all awards, now numbers 18, having recently welcomed to its ranks a new member, Dr. Frank W. Newell, chairman of the section of ophthalmology, department of surgery, University of Chicago Medical School.

Meeting of Surgeons in Miami Beach.—Nearly 100 surgeons from 19 states and three foreign countries, including instructors from 18 medical schools, will present the scientific program at the Southeastern Regional Meeting of the U. S. Section, International College of Surgeons, in Miami Beach, Fla., Jan. 4-7. Sessions will be held in the Americana Hotel. The first day a cinema program will be presented under the direction of Drs. Philip Thorek and Jerome J. Moses, Chicago. Starting Jan. 5, 12 surgical specialties will hold breakfast discussions, with a question-and-answer period for an hour. These will be followed by a general surgery program, with a break for viewing scientific exhibits. Specialty group meetings will be held Monday and Tuesday afternoons. Smith, Kline & French, Philadelphia, will televise operations in color in the mornings from St. Francis Hospital, Miami Beach, to the Americana Hotel. A panel for general practitioners on Tuesday morning has been accorded category I credit by the American Academy of General Practice and will deal with the management of surgical emergencies, with Dr. Ross T. McIntire, Chicago, executive director of the International College of Surgeons, as moderator. Dr. Louis M. Orr of Orlando, Fla., President-Elect of the American Medical Association, will be the banquet speaker the evening of Jan. 6. There will be a $10 registration fee for members of the college and $5 for members of the American Academy of General Practice. Guests, interns, residents, and nurses will be admitted free. Information may be obtained from Dr. Harold O. Hallstrand, general chairman, 7210 Red Road, South Miami, Fla.

Foreign Speakers on Lecture Program.—Dr. Macdonald Critchley, of the National Hospital for Nervous Diseases, London, England, delivered the first Squibb centennial lecture in this country at the Medical College of Virginia, Richmond, Oct. 1 on "Language Disorders—Past, Present and Future." The Squibb Company is sponsoring the appearance in the United States of eight foreign scientists. Additionally, eight outstanding American scientists are included in the program. Other scientists from outside the United States who will deliver Squibb centennial lectures include: Dr. John F. Brock, University of Cape Town, South Africa; Dr. J. F. Danielli, professor of zoology, University of London, England; Dr. J. C. Eccles, Australian National University, Canberra, A. C. T.: Dr. J. H. Gaddum, Edinburgh University, Scotland; Dr. Luis F. Leloir, Biochemistry Research Institute, Buenos Aires, Argentina; Dr. A. Luoff, Institute Pasteur, Paris, France; and Dr. F. Lynen, Max Planck Institute for Cell Chemistry, Munich, Germany.

Medical Record Consultants.—At the annual meeting of the Association of Medical Record Consultants at Boston Oct. 17, Mr. Stephen S. Henkin, medical record consultant of the Health Insurance Plan of Greater New York, was reelected president and Adaline C. Hayden, Associate Editor of Standard Nomenclature of Diseases and Operations, American Medical Association, was reelected secretary-treasurer. The association arranged for its first scientific assembly to be held in Chicago in January, 1960. The meeting will be open to anyone interested in the consulting phases of medical record library science. The association also established a nominee membership to develop educational opportunities in the field of medical record library consultation.

Foundation Grants for Research.—Research Corporation, a nonprofit foundation, distributed as grants-in-aid during fiscal 1958, ended Oct. 31, a total of $1,244,000. The last quarter grants were made among four areas of the foundation's interests:

Frederick Gardner Cottrell Grants—$146,908 granted to 46 colleges and universities in 24 states and to the American University of Beirut for basic research in the natural sciences.

The Williams–Waterman Fund for the Combat of Dietary Diseases—$68,260 granted to universities both in the U. S. and abroad for basic research and experimental programs related to the field of human nutrition.

The Brown–Hazen Fund—$4,700 granted to Baylor University, concerns itself with fundamental research in biochemistry, microbiology, and immunology.

Howard Andrews Poillon Fund—$39,391 granted to four universities in the U. S. for programs of "exceptional scientific merit" which fall outside the scope of the major funds.

Research Corporation was established in 1912 by the late inventor-scientist Frederick Gardner Cottrell, who was professor of chemistry at the University of California. The foundation supports research in the natural sciences in educational and scientific institutions.

Award for Rehabilitation Study.—The World Rehabilitation Fund has created the Arde Bulova Memorial Fellowship in Rehabilitation and the first recipient of the award is to be Dr. Alois Bruegger of Basel, Switzerland. Dr. Bruegger will come to New York in January, 1959, for a six months' course in rehabilitation of paraplegic patients at the Institute of Physical Medicine and Rehabilitation, New York University–Bellevue Medical Center. On completion of his training, Dr. Bruegger, a neurosurgeon, will be the medical director of a special paraplegia unit in the rehabilitation center at the Basel University Hospital. Dr. Howard A. Rusk is president of the World Rehabilitation Fund. The late Mr. Bulova was chairman of the Employer's Subcommittee of the President's Committee on Employment of the Physically Handicapped. The World Rehabilitation Fund is a voluntary agency supported by American industry to help other nations develop rehabilitation services for their physically handicapped.

Commissioners Review Mental Health Programs.—The commissioners who direct the state mental health and hospital programs of 29 states met in Kansas City, Mo., in October, under the auspices of the American Psychiatric Association, to review and analyze trends in these programs and the fiscal and administrative problems underlying them. It was the first time that the commissioners, or those who function as such, had met together as a national group. The commissioners authorized release of a statement which read in part as follows:

> The 49 states are now spending over a billion dollars annually for the operation and construction of mental hospitals. In recent years the results of these heavier expenditures in personnel, in research, and in training are increasingly visible in better patient-staff ratios in the mental hospitals, in decreasing hospital populations despite the highest admission rates in history, and in the greatest number of discharges ever witnessed.
>
> The commissioners are well aware of the pressures upon limited financial resources in the states . . . and of their responsibility for indicating the amount and priority of resources to be devoted to mental illness and health—a problem responsible for the occupancy of half of the total hospital beds of the nation, and affecting at least one in every 10 persons at some point during their lifetime. They are aware that the cost of mental illness to the nation in terms of employment lost and direct expenditures is over $2,500,000,000 a year.
>
> The commissioners have reviewed mental health needs in the light of current trends. . . .
>
> The commissioners affirm their belief that potential advances are magnificently promising and that *NOW* is the time to invest heavily in state mental health and hospital programs. If this is done, it will accelerate a movement which, in the foreseeable future, may be expected to minimize tremendous costs in capital outlays for mental hospital construction and add greatly to the productive potential of the nation.

The commissioners also recorded their intention of organizing as a permanent group to meet regularly to exchange information about their programs and how they may be further advanced. The group at Kansas City designated themselves as a Committee of the Whole pending formal organization. An executive committee was formed to work out the details of organization with Dr. George W. Jackson, Topeka, Kan., as chairman. Commissioners who were not present in Kansas City will be invited to participate in the new organization.

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: Part II only, April 21-22; Parts I and II, June 16-17; Part I only, Sept. 9-10. Examinations must be received at least *six* weeks in advance of a specific examination date. Examining centers established after close of registration. Exec. Sec., Dr. John P. Hubbard, 133 South 36th St., Philadelphia 4.

EDUCATIONAL COUNCIL FOR FOREIGN MEDICAL GRADUATES, INC.

Educational Council for Foreign Medical Graduates, Inc.: Stations around the world, Feb. 17. Deadline for foreign applications was Nov. 17. The following examination will be held Sept. 22 with application deadline of June 22. Exec. Director, Dr. Dean F. Smiley, 1710 Orrington Ave., Evanston, Ill.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: *Written.* Montgomery, June 16-18. Sec., Dr. D. G. Gill, State Office Bldg., Montgomery 4.

ALASKA:* On application in Anchorage and Juneau. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

ARIZONA:* *Written Examination and Reciprocity.* Phoenix, Jan. 14-16. Sec., Dr. Thomas H. Bate, 2910 North 7th Ave., Phoenix.

CONNECTICUT:* *Homeopathic. Examination.* Derby, Jan. 13. Sec., Dr. Donald A. Davis, 38 Elizabeth St., Derby.

DELAWARE: *Written Examination and Endorsement.* Dover, Jan. 13-15, Jan. 22. Sec., Dr. Joseph S. McDaniel, Professional Bldg., Dover.

GEORGIA: *Examination and Reciprocity.* Atlanta, June. Sec., Mr. C. L. Clifton, 224 State Capitol, Atlanta 3.

GUAM: *Subject to Call.* Act. Sec., Dr. F. L. Conklin, Agana.

HAWAII: *Examination.* Honolulu, Jan. 12-13. Sec., Dr. I. L. Tilden, 1020 Kapiolani St., Honolulu.

IDAHO: *Examination and Endorsement.* Boise, Jan. 12-14. Sec., Mr. Armand L. Bird, 364 Sonna Bldg., Boise.

ILLINOIS: *Examination and Reciprocity.* Chicago, Jan. 26-30. Supt. of Registration, Mr. Fredric B. Selcke, Capitol Bldg., Springfield.

MASSACHUSETTS: *Examination.* Boston, Jan. 13-16. Sec., Dr. Robert C. Cochrane, State House, Room 37, Boston 33.

MINNESOTA:* *Examination.* Minneapolis, Jan. 20-22. *Reciprocity.* St. Paul, February. Sec., Dr. F. H. Magney, 230 Lowry Medical Arts Bldg., St. Paul.

MISSOURI: *Examination.* Kansas City, Jan. 9-10. Exec. Sec., Mr. John A. Hailey, Box ???, Jefferson City.

MONTANA: *Examination and Reciprocity.* Helena, April 7. Sec., Dr. Thomas L. Hawkins, 555 Fuller Ave., Helena.

NEBRASKA:* *Examination.* Omaha, June. Director, Mr. Husted K. Watson, Room 1009, State Capitol Bldg., Lincoln 9.

NEW HAMPSHIRE: *Examination and Endorsement.* Concord, Mar. 11-14. Sec., Dr. Edw. W. Colby, 61 So. State St., Concord.

NORTH CAROLINA: *Reciprocity.* Southern Pines, Jan. 17. *Examination.* June. Asst. Sec., Mrs. Louise J. McNeill, 716 Professional Bldg., Raleigh.

NORTH DAKOTA: *Examination and Reciprocity.* Grand Forks, Jan. 7-10. Sec., Dr. C. J. Glaspel, Grafton.

OKLAHOMA:* *Examination.* Oklahoma City, June 2-3. Exec. Sec., Mrs. E. L. Haidek, 813 Braniff Bldg., Oklahoma City.

OREGON:* *Examination.* Portland, Jan. 6-7. *Reciprocity.* Portland, Jan. 8-10. Exec. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland 4.

PENNSYLVANIA: *Examination.* Philadelphia, Jan. 7-10. Sec., Mrs. Margaret G. Steiner, Box 911, Harrisburg.

RHODE ISLAND:* *Examination.* Providence, Jan. 8-9. Admin., Division of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

SOUTH DAKOTA:* *Examination.* Sioux Falls, Jan. 20-21. Exec. Sec., Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

UTAH: *Examination.* Salt Lake City, July 8-10. Dir., Mr. Frank E. Lees, 324 State Capitol Bldg., Salt Lake City 1.

WASHINGTON:* *Examination.* Seattle, Jan. 12-14. Sec., Mr. Thomas A. Carter, Capitol Bldg., Olympia.

WEST VIRGINIA: *Examination and Reciprocity.* Charleston, Jan. 5-7. Sec., Dr. Newman H. Dyer, State Office Bldg. No. 3, Charleston 5.

WISCONSIN:* *Examination and Reciprocity.* Madison, Jan. 13-15. Sec., Dr. Thomas W. Tormey, Jr., 1140 State Office Bldg., 1 West Wilson St., Madison.

WYOMING: *Examination and Reciprocity.* Cheyenne, Feb. 2. Sec., Dr. Franklin D. Yoder, State Office Bldg., Cheyenne.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ARKANSAS: *Examination.* Little Rock, May 4-5. Sec., Dr. S. C. Dellinger, University of Arkansas, Fayetteville.

CONNECTICUT: *Examination.* New Haven, Feb. 14. Exec. Asst., Mrs. Regina G. Brown, 258 Bradley St., New Haven 10.

FLORIDA: *Examination.* Miami, June 6. Sec., Mr. M. W. Emmel, University of Florida, Box 340, Gainesville.

IOWA: *Examination.* Des Moines, Jan. 13. Sec., Dr. Elmer W. Hertel, Wartburg College, Waverly.

KANSAS: *Endorsement.* Kansas City, Jan. 14. *Examination.* Kansas City, Jan. 16-17. Sec., State Board of Healing Arts, Dr. F. J. Nash, New Brotherhood Bldg., Kansas City.

MICHIGAN: *Examination.* Ann Arbor and Detroit, Feb. 12-13. Sec., Mrs. Anne Baker, 116 Stevens T. Mason Bldg., West Michigan Ave., Lansing.

MINNESOTA: *Examination.* Minneapolis, Jan. 6-7. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis 14.

NEW MEXICO: *Examination.* Santa Fe, Jan. 18. Sec., Mrs. Marguerite Cantrell, Box 1522, Santa Fe.

OKLAHOMA: *Examination.* Oklahoma City, Mar. 27-28. Exec. Sec., Mrs. L. Haidek, 813 Braniff Bldg., Oklahoma City.

TENNESSEE: *Examination.* Memphis, Dec. 31-Jan. 1. Sec., Dr. O. W. Hyman, 62 South Dunlap St., Memphis 3.

TEXAS: *Examination.* April 1959. Certificates issued by reciprocity and waiver on the first and fifteenth of each month. Sec., Bro. Raphael Wilson, 407 Perry-Brooks Bldg., Austin.

WASHINGTON: *Examination.* Seattle, Jan. 7-8. Sec., Mr. Thomas A. Carter, Capitol Bldg., Olympia.

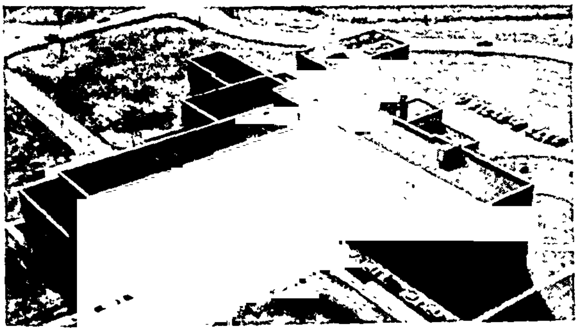
---

*Basic Science Certificate required.

GOVERNMENT SERVICES

AIR FORCE

New Hospital.—The United States Air Force Hospital at Andrews Air Force Base, Washington, D. C., was formally dedicated on Nov. 7. Major Gen. Olin F. McIlnay, deputy surgeon general, in his dedicatory address, stated that this new facility symbolized the many advancements and improvements that have been made in military and clinical medicine. The hospital, which was opened on Aug. 4, has 250 beds located in nine wings. In addition, it can accommodate over 100 transient patients at one time as part of the U. S. A. F. aeromedical evacuation system. The Air Force Clinic, a group of specialty clinics designed to provide examination and treatment of patients on an appointment basis, is staffed and equipped to see about 800 persons daily. A five-story, air-conditioned, brick structure, the hospital has many modern systems including central oxygen distribution, vacuum suction, pneumatic tube message delivery, intercommunications in all clinics and ward areas, radio public address, an audiovisual nurse and doctor paging system, and closed circuit color television service for instruction in professional subjects. Col. Aubrey L. Jennings, M.C., U. S. Air Force, is commander of the hospital and surgeon of headquarters command.



New hospital, Andrews Air Force Base.

Consultants Visit Medical Installations.—Drs. Arthur W. Proetz and Theodore E. Sanders, consultants to the Air Force surgeon general recently visited Air Force medical installations in Germany, France, England, Spain, Libya, and Morocco. Dr. Proetz of St. Louis is a consultant in otolaryngology and Dr. Sanders also of St. Louis is a consultant in ophthalmology. In line with the surgeon general's policy, they advised on problem cases in their respective specialties and conducted lectures and teaching sessions at medical installations.

VETERANS ADMINISTRATION

Hospital News.—Dr. Oskar Diethelm, professor of psychiatry, Cornell University Medical College, addressed the Suffolk County District Branch of the American Psychiatric Association and the staff of the Veterans Administration Hospital, Northport, N. Y., Oct. 28, on "Thyroid Studies in Psychopathologic Disorders."

Dr. Jackson A. Smith, associate director for research, Nebraska Psychiatric Institute, University of Nebraska College of Medicine, Omaha, addressed the staff on Nov. 3, at the VA Hospital, Jefferson Barracks, Mo., on "Lost Tranquility: A Persisting Epidemic."

Dr. Joseph Hirsh, associate professor, Albert Einstein College of Medicine, addressed the staff of the VA Hospital, Northport, New York, Sept. 22, on "The Dimensions and Dynamics of Alcoholism."

PUBLIC HEALTH SERVICE

Water Pollution Report.—A report on the water pollution control program for the fiscal years 1957 and 1958 covering all phases of the program—construction of sewage treatment plants, interstate enforcement activities, research and basic data analyses, and the need for increased public awareness of the water pollution problem—is now available. It may be obtained from the Water Pollution Control Program of the Public Health Service in Washington, or from Regional Engineers in the following cities:

Region 1 and 2, Room 1200, 42 Broadway, New York 4; Region 3, 700 E. Jefferson St., Charlottesville, Va.; Region 4, Room 164, 50 Seventh St. N. E., Atlanta 23, Ga.; Region 5, Room 200, 69 W. Washington St., Chicago 2; Region 6, 2305 Federal Office Bldg., 911 Walnut St., Kansas City 6, Mo.; Region 7, Ninth Floor, 1114 Commerce St., Dallas 2, Texas; Region 8, Room 551, 621 17th St., Denver 2; Region 9, 447 Federal Office Bldg., Civic Center, San Francisco 2.

Personal.—Dr. H. van Zile Hyde has been appointed assistant to the surgeon general for international health. Dr. Hyde, who entered public health as a full-time career in 1941, was active in the United States preparations for the formation of the World Health Organization 10 years ago. He has served as chairman of the WHO Executive Board and on the directing council of the Pan American Sanitary Organization.

DEATHS

Adams, Warren Sanford, New York City; Bellevue Hospital Medical College, New York City, 1897; died Oct. 20, aged 95.

Agnew, Lloyd Campbell Ⓜ Lynchburg, Va.; born in Charleston, S. C., Jan. 9, 1916; Medical College of South Carolina, Charleston, 1939; specialist certified by the American Board of Anesthesiology; member of the American Society of Anesthesiologists and the Lynchburg Academy of Medicine; veteran of World War II; interned at the University Hospitals in Iowa City, Iowa, where he served a residency; served a residency at the Joseph H. Pratt Diagnostic Hospital in Boston and the Georgetown University Hospital in Washington, D. C.; associated with the Lynchburg General Hospital and the Virginia Baptist Hospital; died in the University of Virginia Hospital in Charlottesville Oct. 8, aged 42.

Aronson, Joseph David, Philadelphia; born in Russia Jan. 12, 1887; Medico-Chirurgical College of Philadelphia, 1908; professor of bacteriology at the Henry Phipps Institute of the University of Pennsylvania; at one time professor of pathology at the University of Arkansas School of Medicine in Little Rock; specialist certified by the American Board of Pathology; member of the American Association of Pathologists and Bacteriologists, American Society for Experimental Pathology, American Association of Immunologists, American Association for the Advancement of Science, and the American Trudeau Society; in 1935 was appointed special expert on tuberculosis in the Indian Service under the U. S. Department of Interior and in 1950 was presented with its Distinguished Service Award for his work in connection with control of tuberculosis among American Indians; in recognition of his studies on the evaluation of BCG vaccine in the control of tuberculosis, the College of Physicians of Philadelphia on July 14, 1947, awarded him the Alvarenga Prize; veteran of World Wars I and II; aged 71; died Oct. 17 of coronary heart disease, in Paramaribo, Surinam, Dutch Guiana, where he went to study leprosy.

Barber, John Raymond, Santa Cruz, Calif.; Rush Medical College, Chicago, 1902; served in the regular Army; veteran of World War I; died Sept. 21, aged 80, of heart disease.

Barnes, Lewis Chesley, Hamburg, Ark.; University of Tennessee College of Medicine, Memphis, 1912; past-president and secretary of the Ashley County Medical Society; served as medical examiner for the Ashley County Draft Board during World Wars I and II; city and county health officer; died in the Lake Village (Ark.) Infirmary Oct. 4, aged 72, of coronary thrombosis.

Beisbarth, Albert Ⓜ St. Louis; Beaumont Hospital Medical College, St. Louis, 1899; associated with St. Anthony's and St. Mary's hospitals; died in St. Luke's Hospital Oct. 16, aged 80, of coronary thrombosis.

Beringer, Lester Eastwood Ⓜ Colorado Springs, Colo.; Marquette University School of Medicine, Milwaukee, 1915; service member of the American Medical Association; fellow of the American College of Surgeons; entered the medical corps of the U. S. Army in 1920; veteran of World Wars I and II; retired Aug. 31, 1951; died in U. S. Army Hospital, Fort Carson, aged 67, Aug. 23, of acute pulmonary edema due to myocardial infarction and arteriosclerotic heart disease.

Berman, Joseph Ⓜ Brooklyn; Long Island College Hospital, Brooklyn, 1927; died in the Evangelical Deaconess Hospital Sept. 25, aged 55, of acute coronary occlusion.

Bishop, Vernon Leslie, Rochester, N. Y.; University of Buffalo School of Medicine, 1907; life fellow of the Rochester Academy of Medicine; specialist certified by the American Board of Otolaryngology; veteran of World War I; on the staff of the Highland Hospital; died Oct. 5, aged 74.

Bonar, Everett Twinem Ⓜ La Jolla, Calif.; Ohio State University College of Medicine, Columbus, 1920; member of the Ohio State Medical Association; for many years practiced in Columbus, Ohio, where he was on the staffs of St. Anthony and White Cross hospitals; died Sept. 28, aged 65.

Bouslough, Elmer E., Aurora, Ill.; the Hahnemann Medical College and Hospital, Chicago, 1893; died in the Galena Boulevard Hospital July 21, aged 94.

Brown, Alfred, Chicago; Atlanta College of Physicians and Surgeons, 1912; died in Evergreen Park, Ill., July 6, aged 76.

Campbell, William Ⓜ Jackson Heights, N. Y.; Long Island College Hospital, Brooklyn, 1909; affiliated with Flushing (N. Y.) Hospital and Dispensary; died Sept. 28, aged 79, of arteriosclerotic heart disease.

Cipriani, John Baptist, Des Plaines, Ill.; University of Illinois College of Medicine, Chicago, 1913; at one time on the faculty of his alma mater; served as managing officer of the Illinois Eye and Ear

---

Ⓜ Indicates Member of the American Medical Association.

Infirmary in Chicago; formerly on the staffs of West Suburban Hospital in Oak Park, and St. Elizabeth Hospital, St. Anne's Hospital, and Mother Cabrini Hospital in Chicago, where he was first president from 1927 to 1933; associated with the old Chicago Surface Lines and continued as a physician with Chicago Transit Authority's medical department; died in the Chicago Wesley Memorial Hospital Oct. 20, aged 67.

Condon, John Joseph, Chicago; Northwestern University Medical School, Chicago, 1911; veteran of World War I; formerly practiced in Bloomington, where he was on the staff of St. Joseph Hospital; died in St. Joseph Hospital Oct. 13, aged 69, of carcinoma of the lung.

Cousins, Sidney Charles Ⓢ Washington, D. C.; George Washington University School of Medicine, Washington, 1916; served in France during World War I; associated with Doctors, Georgetown, George Washington University, Providence, and District of Columbia General hospitals and Suburban Hospital, Bethesda, Md.; died in San Francisco Oct. 11, aged 65, of coronary occlusion.

Donnelly, Edward John Ⓢ Philadelphia; Jefferson Medical College of Philadelphia, 1931; assistant professor of clinical ophthalmology at his alma mater; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the International College of Surgeons and the American College of Surgeons; on the staffs of the Philadelphia General Hospital and St. Vincent's Hospital for Women and Children, and the Wills Eye Hospital, where he died Oct. 11, aged 52, of coronary occlusion.

Dougherty, Edward Francis, St. Petersburg, Fla.; Tufts College Medical School, Boston, 1924; veteran of World War I; interned at Rhode Island Hospital in Providence, R. I., where for many years he practiced and where he was chief of staff at St. Joseph's Hospital; retired from the Veterans Administration March 31, 1955; died in St. Anthony's Hospital Oct. 2, aged 64, of acute myocardial infarction.

Elder, Eugene E. Ⓢ Youngstown, Ohio; born March 22, 1890; Magyar Királyi Pázmány Petrus Tudományegyetem Orvosi Fakultasa, Budapest, Hungary, 1922; member of the American Psychiatric Association; superintendent of the Woodside Receiving Hospital; for six years assistant superintendent of the Massillon (Ohio) State Hospital; served with the Austrian troops and was captured by the Russians; in 1917 was transferred to Siberia, where he remained four years, serving as prison camp physician; came to America from Budapest in 1924; died in St. Francis Hospital, Miami Beach, Fla., Oct. 2, aged 68, of myocardial infarction and generalized arteriosclerosis.

Hitchins, Clayton Stanley Ⓢ New Haven, Conn.; Cornell University Medical College, New York City, 1938; assistant clinical professor of obstetrics and gynecology at Yale University School of Medicine; specialist certified by the American Board of Obstetrics and Gynecology; attending obstetrician and gynecologist at Grace–New Haven Community Hospital, where he died Oct. 14, aged 46, of carcinoma of the testis with metastases.

Iliff, Frances Jessie, Cincinnati; Laura Memorial Woman's Medical College, Cincinnati, 1897; died in the Emerson A. North Hospital July 15, aged 84.

Johnson, Frank Ⓢ Eldorado, Ill.; Barnes Medical College, St. Louis, 1902; died in Galatia July 18, aged 86.

Ketchersid, John Wesley, Albuquerque, N. M.; Vanderbilt University School of Medicine, Nashville, Tenn., 1898; died in Las Vegas, Sept. 28, aged 80.

Klotz, Fred Guth Ⓢ Allentown, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1911; fellow of the American College of Surgeons; past-president of the Lehigh County Medical Society; on the staff of the Allentown General Hospital; for many years physician for the Lehigh County Prison; died Sept. 27, aged 71, of pulmonary edema and arteriosclerotic heart disease.

Kvitek, Louis Charles Ⓢ Hinsdale, Ill.; Chicago College of Medicine and Surgery, 1916; died Oct. 11, aged 67.

Lipschutz, Sigmund W. Ⓢ Brooklyn; New York Homeopathic Medical College and Flower Hospital, New York City, 1921; died Sept. 12, aged 61, of acute coronary thrombosis.

McCarthy, Daniel Joseph, Philadelphia; born in Philadelphia June 22, 1874; University of Pennsylvania Department of Medicine, Philadelphia, 1895; served as professor of medical jurisprudence at his alma mater and the Woman's Medical College of Pennsylvania; an associate member of the American Medical Association; fellow of the American College of Physicians; member and past-president of the American Neurological Association and the Philadelphia Neurological Association; member of the American Psychiatric Association; a founder of the National Tuberculosis Association; named director of the Medical Department of Municipal Court in 1935 and in 1942 became director of probation, serving until 1948; veteran of World War I; a neurologist with the Army of Occupation in Germany; was in charge of the neurologic foundation at Temple University which was created for the study and treatment of nervous conditions arising from modern living conditions; served as chairman of the State Council of the Mental Hygiene Division of the Public Charities Association of Pennsylvania; in 1950 elected chancellor of

Florida Southern College, Lakeland, which in 1951 awarded him the degree of doctor of laws; in 1954 Dr. McCarthy was awarded the "Distinguished Service Cross" by Palm Beach County Tuberculosis and Health Association, Inc., for his many contributions to the tuberculosis program over 50 years; consultant, State Hospital at Norristown, Pa.; consulting neurologist at Philadelphia General Hospital and St. Agnes Hospital; editor of "Medical Treatment of Mental Diseases"; died in Ventnor, N. J., Oct. 9, aged 84.

Muhly, Edward George Ⓜ Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1900; professor emeritus of histology at his alma mater; died in the Hahnemann Hospital Oct. 10, aged 80, of congestive heart failure, uremia, and myocardial infarction.

Onesti, Silvio Joseph Ⓜ San Francisco; Medical Department of the University of California, San Francisco, 1899; died Oct. 5, aged 83, of arteriosclerotic heart disease.

Platt, Marden Henry, Riverside, R. I.; University of Vermont College of Medicine, Burlington, 1910; during World Wars I and II served on the Selective Service Board of Providence County number 2; associated with the Memorial Hospital in Pawtucket; died Sept. 28, aged 72, of heart disease.

Rhodes, Goodrich Barbour, Cazenovia, N. Y.; Columbia University College of Physicians and Surgeons, New York City, 1902; member of the founders group of the American Board of Surgery; member of the Southern Surgical Association; fellow of the American College of Surgeons; veteran of World War I; formerly associated with the U. S. Public Health Service; at one time practiced in Cincinnati, where he was on the staff of the Cincinnati General Hospital; died Oct. 5, aged 82, of chronic arteriosclerotic myocarditis.

Ross, Lucretius Henry Ⓜ Bennington, Vt.; Harvard Medical School, Boston, 1898; president of the Bennington Water Board; in 1955 published a book on birds; on the staff of the Putnam Memorial Hospital, where he died Oct. 10, aged 91.

Russell, Claude Vernard Ⓜ Lansing, Mich.; Rush Medical College, Chicago, 1906; past-president of the Ingham County Medical Society; chief of staff. Edward W. Sparrow and St. Lawrence hospitals; charter member of the Lansing Rotary Club; died Sept. 25, aged 77, of acute coronary occlusion and diabetes mellitus.

Sanders, Leighton Albert, Durham, N. H.; University of Vermont College of Medicine, Burlington, 1932; resident physician at the Hood Infirmary at the University of New Hampshire; died in the New Hampshire State Hospital, Concord, Sept. 24, aged 51, of acute asthma (asphyxia), hypertension, and chronic nephritis.

Sanders, Lewis Jackson, Fort Necessity, La.; College of Physicians and Surgeons, Memphis, Tenn, 1911; died in Monroe Sept. 22, aged 92, of cerebrovascular accident.

Schaller, George Jacob, Fort Lauderdale, Fla.; Michigan College of Medicine and Surgery, Detroit, 1897; veteran of World War I; died in Boston, Mich., July 23, aged 86, of coronary thrombosis.

Schmitt, Alexander Hunter, New York City; University and Bellevue Hospital Medical College, New York City, 1907; an associate member of the American Medical Association; fellow of the American College of Surgeons; served as president of the medical board of Misericordia Hospital, where he was a consultant; died Oct. 12, aged 74.

Seebert, Joseph Eldred, Lexington, Va.; Jefferson Medical College of Philadelphia, 1916; veteran of World War I; died in Stonewall Jackson Hospital Sept. 26, aged 66, of complications as the result of a fractured hip.

Smith, De Witt Talmage Ⓜ Gainesville, Fla.; University of Alabama School of Medicine, Mobile, 1907; served as a member of the city council; on the staff of the Alachua General Hospital, where he died Sept. 23, aged 77, of cerebral hemorrhage.

Smith, L. C., Henderson, Tenn.; Memphis (Tenn.) Hospital Medical College, 1902; died Sept. 25, aged 84, of bronchopneumonia.

Sparks, Francis Rufus Ⓜ Waverly, Iowa; Northwestern University Medical School, Chicago, 1904; fellow of the American College of Surgeons; past-president of the Bremer County Medical Society; veteran of World War I; a charter member and past-president of the Waverly Rotary Club; on the staff of St. Joseph's Mercy Hospital, where he died Oct. 2, aged 76, of cerebral thrombosis.

Spence, James Earle Hassard Ⓜ Hagerstown, Md.; University of Toronto Faculty of Medicine, Toronto, Ontario, Canada, 1923; served as resident surgeon for the Western Maryland Railway; died in the Washington County Hospital Sept. 27, aged 62, of coronary occlusion.

Stacey, Winthrop Downing, Melrose, Mass.; Tufts College Medical School, Boston, 1906; veteran of World War I; practiced in Boston; died in the New England Sanitarium and Hospital Sept. 14, aged 76, of arteriosclerotic heart disease.

Stasiunas, Juozas Joseph, Chicago; Imperial Military Medical Academy, St. Petersburg, Russia, 1917; interned at Roseland Community Hospital in Chicago; served as resident, State Hospital, Jamestown, N. D.; died in the Hospital of St. Anthony de Padua July 24, aged 64.

Stayton, Chester A., Sr. Ⓜ Indianapolis; born in Centerton, Ind., April 29, 1889; Indiana University School of Medicine, Indianapolis, 1915; formerly on the faculty of his alma mater; specialist certified by the American Board of Radiology; fellow of the American College of Radiology; member of the Radiological Society of North America, American Radium Society, and the Industrial Medical Association; served as secretary of the Indianapolis Medical Society; served as president and secretary-treasurer of the Indiana Roentgen Society; veteran of World War I; formerly associated with the U. S. Public Health Service Reserve; director of the Indiana Division of the American Cancer Society, of which he was National director; founder and formerly editor of the *Indianapolis Medical Society Bulletin;* associated with Witham Hospital, Lebanon, Ind., St. Francis Hospital, Beech Grove, and the Community Hospital and the Methodist Hospital, where he died Oct. 8, aged 69, of cerebral hemorrhage.

Stevenson, Arthur P. Ⓜ Torrance, Calif.; Ensworth Medical College, St. Joseph, Mo., 1907; on the staff of the Torrance Memorial Hospital, where he died Sept. 27, aged 73, of bronchogenic cancer.

Strickland, Harold Ⓜ Meriden, Conn.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1930; certified by the National Board of Medical Examiners; veteran of World Wars I and II; past-president of the local board of health; in 1948 vice-president of the Meriden Medical Society; associated with the Meriden Hospital and World War II Veterans Memorial Hospital; died Oct. 6, aged 60, of coronary thrombosis.

Stuck, Robert Gustavus Ⓜ Wolcott, N. Y.; Syracuse (N. Y.) University College of Medicine, 1924; past-president of the Wayne County Medical Society; member of the American Academy of General Practice; served as a member of the board of education and as health officer; veteran of World Wars I and II; charter member and past-president of Wolcott Rotary Club; on the staff of the Edward J. Barber Hospital in Lyons; founder and owner of the Wolcott Hospital, where he died Sept. 24, aged 59, of Hodgkin's disease.

Swanson, Harry Theodore Ⓜ Evanston, Ill.; Loyola University of Medicine, Chicago, 1916; member of the American Academy of General Practice; veteran of World War I; died in the Chicago Wesley Memorial Hospital Oct. 15, aged 69, of acute intrathoracic hemorrhage and bronchogenic cancer.

Taylor, Frank Bashford Ⓜ Madison, Wis.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904; on the staffs of the Madison General and St. Mary's hospitals; died Sept. 25, aged 79, of arteriosclerosis.

Tenney, William Northend, Newton, Mass.; Harvard Medical School, Boston, 1895; served overseas during World War I; died in the Newton–Wellesley Hospital Sept. 10, aged 89, of cancer of the prostate and bronchopneumonia.

Terry, Philip Roy, Asheville, N. C.; George Washington University School of Medicine, Washington, D. C., 1907; coroner of Buncombe County; vice-president of the National Coroners' Association; at one time practiced in Washington, D. C.; served as county jail physician and prison camp physician; died Sept. 29, aged 78, of coronary occlusion.

Thomas, Henry S. Ⓜ Fort Washington, Pa.; born in Parker Ford, May 26, 1905; Temple University School of Medicine, Philadelphia, 1935; served as a command flight surgeon in the Army Air Force from 1941 to 1946 with the rank of lieutenant colonel; after release from active duty became medical director of Ciba Pharmaceutical Products, Inc., and later of Nepera Chemical Company; director of medical service, Merck Sharp & Dohme Research Laboratories, which he joined in 1951 as assistant medical director; member of the Aero Medical Association and the Association of Military Surgeons of the United States; died Oct. 9, aged 53, of coronary thrombosis.

Thompson, John Maurice Ⓜ Van Nuys, Calif.; born in St. Louis Dec. 3, 1911; University of Cincinnati College of Medicine, 1941; fellow of the American College of Surgeons; specialist certified by the American Board of Surgery; assistant clinical professor of surgery at the University of California School of Medicine at Los Angeles; veteran of World War II; awarded the Presidential Unit Citation and Combat Medal Badge; interned at Missouri Baptist Hospital in St. Louis; served a residency at Veterans Administration Center in Los Angeles; on the staffs of St. Joseph Hospital in Burbank and Presbyterian Hospital–Olmsted Memorial, Los Angeles; consultant, Veterans Administration Hospital in Sepulveda; on the staffs of Encino Hospital and West Valley Community Hospital in Encino, and the Valley Hospital; trustee and medical adviser on the board at Valley Presbyterian Hospital, where last March he was presented with a plaque in appreciation of work in organizing the hospital and where he died Oct. 3, aged 46, of bronchogenic carcinoma.

Tracy, George Thomas Ⓜ Beverly, N. J.; Jefferson Medical College of Philadelphia, 1898; past-president and secretary of the Burlington County Medical Society; member of the board of managers of the State Hospital in Trenton; died Oct. 2, aged 85.

Trankle, Herbert Milo, Chippewa Falls, Wis.; Rush Medical College, Chicago, 1901; formerly practiced in Bloomer, where he served on the city council and school board; served on the staff of Northern Wisconsin Colony and Training School; honorary staff member, St. Joseph's Hospital, where he died Sept. 21, aged 78, of coronary thrombosis and diabetes mellitus.

AUSTRIA

Unusual Types of Plasmocytoma.—At the meeting of the Society of Physicians in Vienna on Oct. 17, Drs. S. Wuketich and G. Siegmund briefly reviewed Schulten and Kanzow's classification of paraproteinemic reticulosis into three types, namely plasmocytoma, atypical macroglobulinemia, and Waldenström's macroglobulinemia. They reported a series of six patients with plasmocytoma examined at autopsy. Histological preparations revealed immature cellular plasmocytomas and neoplastic reticulosis with a plasmacytic differentiation. In only one case was an extramedullary generalization with infiltration of the lymph nodes present. Remarkable deviations could be detected by analyzing the serum proteins. The serum lability reaction (extremely shortened Weltmann coagulation band and negative thymol, cadmium, and distilled water reaction) showed an abnormal stability of the serum. Paper electrophoresis revealed paraprotein double bands lying close together in the beta area; partly a remarkable broad, very strong beta band which has a lighter boundary toward gamma, and a somewhat masked beta double band. Tiselius electrophoresis always shows a separation of the large beta myeloma gradient into two or three subfractions. With the aid of analytical ultracentrifugation, so-called atypical macroglobulins with sedimentation constants of 8 to 14 Svedberg units were found. The peculiar chemical albumin findings in the mentioned plasmocytoma types were considered as a new constellation in the reaction of the serum proteins, namely as a type of the beta-plasmocystoma with atypical macroglobulinemia.

Hormone Which Inactivates Oxytocin.—At the meeting of the society of physicians in Vienna on Oct. 24, Dr. W. Müller-Hartburg described a technique for chemically determining the oxytocinase level in the serum. The oxytocinase activity in the serum had previously been measured by biological assay. The substrate, L-cystine-di-beta-naphthylamide is decomposed by the action of oxytocinase with splitting off of the colorimetrically measurable beta-naphthylamines. In the examination of 365 serums the enzyme activity was found to increase progressively in healthy pregnant women up to the moment of birth. The oxytocinase level showed either a temporary or permanent decrease in the 10th lunar month in a small percentage of women. The level was highest in most of the pregnant women at the time of delivery. It returned to the normal level of a nonpregnant woman within six weeks.

The blood of the umbilical cord showed the normal level of a nonpregnant woman, and the retroplacental blood showed the highest level observed. No aminopeptidase activity could be detected in the amniotic fluid. Benign or malignant tumors of the sex organs did not change the oxytocinase level of the serum. Patients with certain hepatic diseases showed a marked rise of the aminopeptidase activity. In patients with hyperemesis gravidarum the oxytocinase level in the serum was 13% lower than in healthy patients. Extrauterine and intrauterine pregnancy of the same duration showed equal levels. In a woman with genuine prolongation of pregnancy beyond term a decrease of the oxytocinase level in the serum was observed after the patient reached the calculated term.

Oxytocinase blocking agents may not be present in the serum of patients who are not pregnant. Sudden fluctuations in the oxytocinase level in the presence of severe hemorrhages during pregnancy, parturition, and immediately after birth may be explained by changes in the fluid balance in the body. Oxytocinase does not seem to be responsible for the presence of aminopeptidase activity in the serum of women who are not pregnant, of men, and of patients with hepatic diseases. Measurement of the oxytocinase level constitutes an accurate chemical test for pregnancy and gives the approximate age of the fetus.

BRAZIL

Tolazoline and Lymph Node Biopsy.—Dr. B. Guida Jr. studied the usefulness of tolazoline and cervical lymph node biopsy in a series of 102 patients with lung lesions and with cancer of the esophagus (*Rev. paulista med.* 53:234, 1958). The series was divided into two groups. Group 1 consisted of 53 patients suspected of having pulmonary cancer and group 2 of 49 suspected of having cancer of the esophagus. In group 1, 37 had a histological diagnosis of cancer and the remaining 16 had other diagnoses or no diagnosis. The author studied the results of the biopsy in its relationship with the pulmonary localization of the lesion and the presence or absence of palpable nodes in the supraclavicular region. He found that in 37 patients the tolazoline biopsy gave a correct diagnosis in 20, thus eliminating the necessity of using other examinations. The

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

tolazoline biopsy offered the possibility of a diagnosis by a simple technique, as the surgical procedure may be performed with local anesthesia in an outpatient clinic. Endoscopy, used in 14 cases, confirmed the diagnosis in 5. In only 10 patients was thoracotomy performed for the confirmation of the diagnosis. In 17 there were palpable nodes at the base of the neck. Of these, 13 had a positive diagnosis of cancer. On the other hand, of the 19 without palpable nodes at the base of the neck, 7 had positive biopsy findings. The presence of palpable nodes does not indicate, nor does their absence rule out, metastases. In the 16 patients with negative biopsy findings, 7 were subjected to exploratory thoracotomy, which led to the discovery of five cases of pulmonary abscess and two of aortic aneurysm.

Of the 49 patients with esophageal cancer, 31 had a positive histological diagnosis. The diagnosis of the rest was based on clinical and radiologic findings. Biopsy was performed in 23 on the right and in 26 on the left side. There were palpable nodes in 21—3 in the upper, 5 in the middle, and 13 in the lower third. In this group of 21 patients, the biopsy was negative in the nodes from the middle and upper thirds and positive in 7 of those from the lower third. The biopsy was performed on the side of the palpable nodes. In the patients with no palpable nodes, a single biopsy was positive in two on the right side, from a total of three taken from the middle third. There was one positive biopsy in four patients with no palpable nodes in the left side, taken from the lower third. Thus, of the 49 patients in group 2, the biopsy was positive in 9. Tolazoline biopsy appeared to be indicated in patients suspected of having cancer of the esophagus whenever there is a palpable node in the supraclavicular region or whenever the endoscopic biopsy is negative.

Cancer of the Uterus.—Dr. Arnaldo de Moraes and co-workers (*An. brasil. ginec.* 46:61, 1958) compared colposcopy, colpocytology, and biopsy for the early detection of cancer of the uterus. They found this a complex problem. Considering only colposcopy and cytology, they concluded that what was really being compared was the personal efficiency of the investigators. Their files included more than 9,000 cases, reduced to 8,542 after the elimination of incomplete records. After a second selection of patients suspected of having cancer of the uterus by one or more of the methods of examination, they studied a series of 660 cases which were divided as follows: 359, or 54.4%, that showed agreement of colposcopy, colpocytology, and biopsy; 32, or 4.7%, that showed agreement of colposcopy and biopsy; 23, or 3.4%, that showed agreement of cytology and biopsy; 52, or 7.8%, that showed agreement of colposcopy and cytology; 106, or 16.6%, in which the tentative diagnosis was based on colposcopy only; 67, or 10.0%, in which it was based on cytology only; and 21, or 3.1%, in which it was based on biopsy only. Thus the total agreement between cytology and colposcopy amounted to 62.2% of the cases. The greater number of positive diagnoses by means of colposcopy (66.9%) may be explained by the inclusion of patients with minimal lesions (small mosaic areas, erosions, and noncharacteristic proliferations). In 92 patients with positive colpocytologic examinations in stages 3 and 4, the control by repetition revealed a gradual decrease of positivity, eliminating the suspicion of malignancy in more than half of the patients. The authors concluded that, particularly in those with epidermoid cancer, the best results are obtained by the simultaneous use of colposcopy and cytology, which must be considered as concurrent and not as competitive methods of diagnosis.

Acute Pancreatitis.—At a meeting of the Associação Paulista de Medicina, Dr. David Rosenberg reported a series of 275 patients with acute pancreatitis. The age of the patients varied from 6 to 82 years, 111 being between ages 21 to 40 years and 132 between ages 41 to 60 years. About 25 years ago the treatment of acute pancreatitis was mainly surgical, but the tendency is now more and more conservative. This is due principally to the more frequent clinical diagnosis and the observation of a great number of patients cured without operation. Thus, in one group of 47 patients, the early surgical treatment, used in 18, showed a case fatality rate of about 50%, while in 27 treated conservatively this rate was only 18.5%. The medical treatment aims principally at alleviating the pain; combating the shock by transfusion; correction and maintenance of the electrolyte, caloric, and vitaminic equilibrium; preventing infection by means of antibiotics; and inhibiting the pancreatic secretion by dieting. These general measures were used on 207 patients, with 28 deaths (13.5%). Surgical treatment was used on 68 patients, with 19 deaths (27.9%). In 13 of the latter the operation was exploratory. The exploratory laparotomy was performed in cases of wrong (9) or doubtful diagnosis. In most of these patients, as the true diagnosis was established, medical treatment was instituted. Dr. Rosenberg concluded that the surgical treatment of patients with acute pancreatitis has very limited indications.

INDIA

Vaginal Cytology.—Malkani and Sikand (*Journal of Association of Medical Women in India,* vol. 46, Aug., 1958) stated that as the endometrium reflects the activity of the ovaries, examination of the endometrium at suitable intervals can be used to ascertain the possible cause of amenorrhea and to indicate the response to various drugs. Endometrial biopsy may cause some discomfort to the patient, while the collection of vaginal smears is a much simpler procedure and repeated examination of such smears can help in following the response to therapy for restoring menstruation in patients with amenorrhea. The authors studied 29 such patients. Amenorrhea after removal of uterus or ovaries, after radiation, and during pregnancy and lactation was not included in this study. No patient with a history of amenorrhea of less than six months duration was included. Primary amenorrhea was assumed if the menarche had not occurred by the 18th year.

Endometrial biopsy was performed once a week for six to eight weeks and vaginal smears were taken on alternate days during the same period. The ovarian function was graded from the vaginal cytology according to the method of De Allende and Orias, and the endometrial biopsy was dated according to the method of Hertig and Rock. The results were then correlated. Three patients in this series had primary amenorrhea, and 26 had a secondary type of amenorrhea. The age of the patients varied from just under 20 to 35 years. The age at menarche in the patients with secondary amenorrhea ranged from 12 to 15 years. Menstrual history was normal in 12 patients, oligomenorrhea was present in 6, menorrhagia in 5, and hypomenorrhea in 3. The duration of secondary amenorrhea varied from six months to six years. The secondary sex characteristics were normally developed in 24 patients, underdeveloped in 4, and of masculine type in 1. Pelvic examination gave normal findings in 10; a hypoplastic uterus was present in 7, a bulky uterus in 1, pathological adnexa were found in 10, and a cystic ovary in 1.

An atrophic vaginal cytology curve was observed in 12 patients and indicated an absent or markedly insufficient ovarian function, but whether the ovarian failure was due to local ovarian disease or was secondary to disease of the pituitary or hypothalamus could not be determined from the vaginal smear. An acyclic hypotropic curve was observed in five patients. It showed a consistently low estrogenic level which was insufficient to produce menstruation. A cyclic hypotrophic curve was seen in six patients and indicated an estrogenic level lower than normal but sufficient to produce menstruation. A eutrophic curve was noted in one patient and a high cornification type of cytology was seen in three, the latter signifying a persistently high estrogenic level. Two patients had the findings of a persistent luteal phase. The results of endometrial biopsy showed an atrophic endometrium in eight patients, an early proliferative phase in six, a proliferative phase with dilated glands in two, a secretory phase in two, a proliferative changing to secretory phase in one, a tuberculous endometritis with proliferative phase in three, and tuberculous endometritis with loss of endometrial structure in seven.

The diagnosis of these 10 patients with tuberculous endometritis would have been missed if the vaginal cytology alone had been studied, and the ovarian function in 16 could not have been determined by studying only the endometrium without examining the vaginal smears. In 13 patients vaginal cytology and endometrial biopsy gave identical information as far as ovarian function was concerned. Thus, vaginal cytology was found to be the method of choice for studying ovarian function and endometrial biopsy was indispensable for diagnosing endometrial tuberculosis. A study of vaginal cytology is also important for prognosis. Atrophic cytologic findings indicate a poor prognosis and a persistent luteal phase or persistent high cornification curve indicates a more favorable prognosis.

Labor After Previous Cesarean Section.—N. S. Devi studied a series of 50 labors after previous cesarean section over a period of four years (*Journal of Association of Medical Women in India*, vol. 46, May, 1958). One woman delivered naturally twice during this period; 32 had a repeated section (26 for cephalopelvic disproportion, 2 for repeated uterine inertia, 1 for a ruptured lower segment scar, 1 for threatened rupture of a classic scar and uterine inertia, 1 for post-maturity and floating head, and 1 for a floating head and thick cervix) and 18 had a vaginal delivery. In 14 of these forceps were applied to avoid strain on the scar, and 4 were delivered unassisted. There were no maternal deaths but there was one stillbirth in the group who had a repeated section. Of the 50 there were 34 who had had the previous cesarean section because of disproportion. Of these, 25 required repeated section, all for disproportion, and 9 delivered vaginally. Thus, section was not always necessary even in the group with disproportion. The average weight of the babies in the group who had a repeated section was 6.7 lb. (3,040 Gm.), in those delivered by forceps 6.1 lb. (2,768 Gm.), and in those delivered naturally 6.7 lb. Of the remaining 15 belonging to the group of nonrecurrent causes, repeated section was performed on 6 and delivery was vaginal in 9; 7 of these 15 had uterine inertia, 3 had antepartum hemorrhage, 2 had breech presentation, 2 had severe preeclampsia, and one had a tumor complicating pregnancy. Vaginal delivery in this group thus occurred in only 60%.

Repeated section was indicated because of uterine inertia in two patients, rupture of a lower segment scar in one, threatened rupture of a classic scar and uterine inertia in one, a floating head and thick cervix in one, and postmature floating head in another. In the group with disproportion, vaginal delivery occurred in 23.5% as opposed to 60% in the group with a nonrecurrent cause. Thus, once a cesarean section is performed subsequent deliveries need not always be by cesarean section. The type of previous section is important. The lower segment scar ruptured in only 0.3% of the patients in this series while the classic scar gave way in 3.6%. Induction of labor may sometimes be necessary to avoid a repeated section for the possible disproportion that may occur if the pregnancy is prolonged. Thus in one patient who had had a previous lower segment cesarean section, labor was successfully induced at 41 weeks.

Pyracortine.—Bhattacharya and Bhuyan (*Antiseptic,* vol. 55, Sept., 1958) treated 16 patients (6 who had rheumatoid arthritis, 6 who had spondylitis ankylopoietica, 2 who had gout, 1 who had acute rheumatic fever, and 1 who had osteoarthritis), all of whom had moderate to severe pain, with tablets of Pyracortine, each containing 0.75 mg. of prednisone and 150 mg. of amidopyrine. The duration of the disease varied from two days to six years. The subjective and objective improvement including improvement in pain and tenderness of the affected part, swelling, color, temperature, mobility of the painful parts, and changes in the sedimentation rate were observed. A watch for untoward side-effects was kept by noticing changes in body weight, palpation of the liver, appearance of edema, red blood cell counts, hemoglobin level, blood urea, urinalysis, development of skin rashes, and gastric dysfunction.

Patients were observed for a minimum of three days after the stopping of treatment to note development of withdrawal effects. The total duration of treatment was 12 days. The results of treatment were excellent in one patient with acute gout and one with acute rheumatic fever; in three with spondylitis ankylopoietica and one with rheumatoid arthritis they were good; in five they were fair; and in five they were poor. There was no correlation between the type and duration of disease and the response to treatment. The sedimentation rate of eight patients fell but changes in the sedimentation rate had no relation to the clinical response to treatment. In the two patients with gout, the blood uric acid showed a reducion of 20 to 25%. A slight increase in weight was seen in a few patients. No dyspeptic symptoms were noticed. In six patients a slight fall in the total leukocyte count was noticed and in three this count showed a rise. In five the hemoglobin level had increased at the end of treatment. The liver did not show any changes clinically. The blood urea level was normal in all patients and the urinalysis did not show any abnormality. No skin reaction was noted.

Acute Nephritis.—A. Girija studied a series of 100 children with acute glomerulonephritis with special reference to cause and clinical features (*Antiseptic,* vol. 55, Sept., 1958). The disease probably runs a more benign course in India due to the lower protein intake and the predominantly carbohydrate diet. More than half of the patients belonged to the age group 3 to 7 years (range 3 mo. to 11 years). The sex ratio was 61 boys and 39 girls. Only one patient had a family history of acute nephritis. This disease occurred uniformly throughout the year. Twenty-one patients gave a history of scabies a few weeks before the onset of acute nephritis, 10 had a mild respiratory infection prior to the illness, 1 had an extensive seborrhea of the scalp a month before the onset, 1 developed acute nephritis while a boil on the scalp was being treated, in 1 the illness followed vaccination for smallpox, in 1 severe dysentery preceded the onset by one month, and in 1 nephritis followed treatment for ascariasis.

Most of the children came to the hospital for puffiness of the face and slight edema of lower limbs. Almost all had oliguria. Hematuria was commonly seen, but its degree varied. In most patients little disturbance of general health was observed at the onset of the disease. In one severe vomiting was the initial symptom. Edema of varying degrees was present in all but one. Although oliguria was common, complete suppression of urine occurred in only one patient. The urine was dark brown in most patients, and microscopic examination revealed red blood cells in all. Only 27 had fever. Hypertension was not common. Epistaxis occurred in one patient while under treatment. Four had diarrhea, and in 12 the main complaint mentioned by the mother was dyspnea which was due to cardiac failure. These patients showed dulness on percussion and moist rales at the base of the lungs. The heart was involved in 12 patients. Blood protein levels were estimated in three and in all of them they were 3.5 Gm. per 100 c.c. The blood cholesterol level was estimated in some patients, and all of them gave normal values. The blood urea level was elevated to about 65 mg. per 100 c.c. in two patients and in others it was below 40 mg. per 100 c.c. The red blood cell count was often found to be lowered to about 3,500,000, and the hemoglobin level varied from 65 to 70%.

ISRAEL

Health Standards.—Israel's standard of living, as judged by statistics regarding births, infant mortality, crude death rate, and life expectancy, is on the whole far above the comparable level of the other countries of the Middle East. In some respects it compares favorably with that of such countries as the United States, Switzerland, and Sweden. These facts were revealed in the ninth edition of the United Nation Demographic Yearbook. Israel's infant mortality rate in 1956 per 1,000 population was 35.9 for Jewish children. The comparable rate of Egypt was 148.5. Israel's crude death rate (deaths per 1,000 population) was 6.3 for the Jewish population in 1956, while that of Egypt was 18.4. Live births in Israel in 1956 were at the rate of 28.8

per 1,000 population, while in Iraq it was 15.5 and in the United States 24.9. Israel also had a higher life expectancy than any of its Arab neighbors. A one-year-old boy in Israel can reasonably expect to reach the age of nearly 70, while an Egyptian boy who reaches the age of one will, in all likelihood, live only until he is about 44. A 50-year-old Jew in Israel may expect almost 25 more years of life, while an Egyptian man of the same age will probably live another 19 years. Egypt has a tuberculosis case fatality rate of 22.5 per 100,000 population, while the corresponding rate for Jewish residents of Israel is only 5.9.

Jaundice due to Chlorpromazine.—An attempt to prevent jaundice due to chlorpromazine was reported at the Congress of the Israel Medical Association by F. Dreyfuss and co-workers of the Hebrew University Hadassah Medical School and the Talbieh Psychiatric Hospital, Jerusalem. They assumed that the histological and biochemical findings, pointing to intrahepatic obstruction as the mechanism of this complication, might be caused by inspissation of the bile and interference with its flow. They, therefore, gave to patients being treated with chlorpromazine a large additional amount of fluid during the course of administration of the drug. Whereas in the first 362 patients treated with chlorpromazine at the institution 16 cases of jaundice had appeared (4.4%), the number dropped to 2 in 588 (0.34%) so treated when the patients were given about 2.3 liters of sweetened tea or water in addition to their regular fluid intake. There was no difference between the two series as to the selection of patients and the schedule of chlorpromazine treatment.

Sensitivity to Olive Pollen.—Kessler (*Depim Refuim* 18:141, 1958) reported that the pollen of olive trees may sensitize persons disposed to allergy by heredity and provoke seasonal rhinitis, conjunctivitis, bronchial asthma, and skin troubles. In the regions where olive trees grow patients with this kind of sensitivity are frequent. Of all the pollen allergies in Israel this is second only to the sensitivity to pollen of spring grasses. It is the most important kind of pollen allergy from pollinating trees.

Clotting Factors.—A series of 153 patients with thrombophlebitis was studied by C. H. Fryd (*Harefuah* 55:168, 1958). On classifying the patients by country of origin, it was found that they came from 19 countries. The fact that none were from Yemen attracted special attention, since coronary occlusion is rare among Yemenites. A study of thromboplastin generation was therefore carried out among the various ethnic groups, but no clear-cut pattern specific to any group, including Yemenites, was found. On study of the ratio between the platelet count in plasma from blood removed by venepuncture and that in fingertip capillary blood, an apparently significant difference was found. The ratio between these two counts in normal subjects is usually between 1:2 and 1:3. Ratios in this range or higher were found for almost all of the non-Yemenite patients, while Yemenites tended to have lower ratios. Since the platelets play such an important role in clotting, the results of this preliminary study may add to understanding of the problems of thrombosis, and possibly of atheromatosis also.

Psychosis After Asian Influenza.—Z. H. Winnik and co-workers (*Danim Refuim* 18:112, 1958) observed several patients who after Asian influenza developed an acute psychosomatic syndrome characterized by confusion, psychomotor agitation, hallucinations (mostly visual), and delusions. One patient showed periodic catatonia. Psychological complications have been described in connection with various epidemics of influenza, but no communications on neuropsychological complications in connection with Asian influenza have been found, although the disease in 1957 affected mankind on a global scale. Neurological investigation, including spinal fluid examination, did not reveal any pathological changes. The electroencephalogram remained unchanged in three patients but in the fourth signs of a generalized disturbance with a convulsive pattern were seen. In the follow-up of this patient after recession of the psychosis, the tracing showed great improvement but not a complete return to normal. The titer for antibodies of Asian influenza was high and increased as the psychosis progressed. This was accepted as evidence of an acute infection. In all cases the psychosis developed in a personality showing clear indications of a certain predisposition to psychological instability. This predisposition consisted of psychoneurotic character traits. Recent psychic trauma such as acute psychic conflict, prolonged stress, and physical exhaustion were also noted as predisposing factors. The ego of these patients was unable to deal effectively with the added stress of the illness and reacted with an acute psychotic episode. The course of the psychosis was benign. All the patients recovered without special treatment. In view of the extent of the epidemic, it was concluded that the virus was not highly neurotoxic.

NETHERLANDS

Asian Influenza.—J. Mulder and co-workers (*Nederl. tijdschr. geneesk.* 102:1992, 1958) reported the results of their investigations of the 1957 Asian influenza pandemic. Just before its appearance in the Netherlands in June, 1957, the authors examined 1,256 serums for antibodies against the Asian influenza virus. On the whole only persons over 70 showed a positive titer. These titers were independent of evidence of infection with other A-strains occurring in the Netherlands between 1933 and 1956. The authors also showed that no recent infections with the Asian strain had occurred. On the other hand many persons who were over 35 showed a high titer for antibodies against the Shope strain of influenza A virus which caused the 1918 pandemic. The authors concluded that the presence of antibodies against the Asian strain in older persons indicated an earlier contact with this virus. This might have been the virus of the 1889-1890 pandemic, which also started in Asia. The Shope strain has since the 1918 pandemic continued in North American swine with an unchanged antigenic composition. An epidemic among swine in Asia did take place early in 1957. The 1957 pandemic might, therefore, have originated from a persistent carrier state in Asian swine since the 1889-1890 pandemic. The interval between pandemics must be long enough to produce a younger generation susceptible to the virus.

The occurrence of small epidemics between pandemics could be explained by a gradual change of the antigenic structure during the interhuman passage of the virus. In this way low titers for antibodies against the Shope strain in persons born after the 1918 pandemic could be explained. The Asian strain showed a definite pneumotropism for the human lung, but it was not highly virulent. This virulence might increase in the future, however, as a result of a better adaptation of the virus to human tissues. In such a way a second wave of Asian influenza with a higher pneumotropic virulence could be expected.

Blood Transfusions in the Merchant Marine.—Dr. H. B. G. Breijer (*Nederl. tijdschr. geneesk.* 102:1813, 1958) reported on the transfusion service on board the ships of the Royal Rotterdam Lloyd. At first the ships were equipped with only test serums. Difficulties, however, were encountered in finding suitable donors and in determining the Rh factor. In order to avoid these difficulties volunteers were sought among the ship's crew. On the evening before the arrival of the ship, blood samples were taken and sent next day to a laboratory of the official transfusion service. At the beginning of each voyage the ship's doctor received a list of donors available on his ship. On the three main ships with a total capacity of about 4,000 passengers, on the average about 60 donors appeared to be available. The ships' doctors are specially trained in giving transfusions. Thus it has been possible to give on these three ships during the last 18 months 10 transfusions to four patients.

Tuberculosis Death Rates.—According to the Central Office for Statistics in the Netherlands 515 persons or 4.7 per 100,000 population died of tuberculosis in 1957. In 1956 these figures were, respectively, 593 and 5.4. Though there still appears to be a decrease of this mortality rate, this decrease is less prominent than during the previous six years. According to provisional data 7,936 new cases of tuberculosis were reported in 1957. In comparison with 1956 this means an increase of 3%. Probably, however, when the final data for 1957 becomes available a nearly equal morbidity rate for 1956 and 1957 will be found.

UNITED KINGDOM

Bronchitis and Outdoor Occupations.—Dr. D. Reid, at a conference of the National Society for Clean Air, stated that the effect of working out of doors in industrial areas was to increase markedly and specifically the frequency of attacks of disabling bronchitis and other serious respiratory diseases. He gave an account of the results of a survey carried out on government employees, including postmen. After the age of 25 the frequency of bronchitic attacks among postmen increased in all areas but relatively more so in the areas of heavy air pollution. Bronchitis rates appeared to be more closely related to the local level of air pollution, while influenza morbidity was more closely associated with domestic overcrowding. Lung cancer showed only a slight correlation with air pollution but a close one with population density. Pulmonary tuberculosis rates were similar, with a definite association with overcrowding. A simple explanation of these findings is that bronchitis is affected by urban air pollution, while the overcrowding in cities has a greater effect on infectious diseases, such as influenza and tuberculosis. The fact that more densely populated areas had higher lung cancer death rates might be related to increased smoking rather than to air pollution due to the burning of coal.

Data compiled by Gorham suggested a correlation between bronchitis mortality and the pH of the material precipitated in polluted air (*Lancet* 2:691, 1958). Suspended particles of foreign matter act as nuclei for the condensation of droplets of sulfuric acid, and in some areas of hydrochloric acid, so that the town dweller is in fact inhaling an acid aerosol. Gorham estimated that in dry weather evaporation occurred at the surface of the aerosol, which might have a pH below 2 at times. This corresponds to the pH of gastric juice and would undoubtedly act as a bronchial irritant.

Physicians Need Not Give Death Certificates.—According to a ruling by the Minister of Health, when a patient dies the physician ceases to be responsible and is not specifically obliged to issue a death certificate. The Minister allowed an appeal by a physician in Kent against a decision by his local executive council that he failed to provide proper treatment for a patient, who had since died. The council had recommended a penalty of $280. The facts were that a patient was dying, or may even have been dead, when a relative summoned the doctor several times without success. A call was made in the evening for a death certificate by the relatives, who believed the patient to be dead, and they expressed their feelings in no uncertain terms to the physician. The matter was referred to the local executive committee, which decided that the doctor was negligent. The Minister reversed this decision and held that the physician had not actually failed to treat a patient, which under his terms of service he was obliged to do. This ministerial ruling would suggest that if a doctor thinks a patient to be dead he need not make a visit to confirm the fact and that he is under no statutory obligation to issue a death certificate.

Amphetamine Psychosis.—Dr. P. Connell has collected 42 cases of amphetamine psychosis (Amphetamine Psychosis, London, 1958). The psychosis developed in 8 patients after they had taken a single dose, in 4 after they had taken amphetamine and alcohol, and in 30 after repeated medication for a month or more. So severe were the symptoms that 39 of the patients were hospitalized, 26 of them in an observation ward. In about 40%, amphetamine, or one of its derivatives, had been given for tiredness, depression, or obesity—dextroamphetamine usually being given for the treatment of the latter. Some patients were veritable amphetamine addicts, one taking as much as 975 mg. of amphetamine. Such quantities can be obtained by breaking open amphetamine inhalers. Many of the patients were addicted to other drugs or to alcohol, but some normal and apparently well-adjusted persons were affected by these drugs.

The initial diagnosis was often schizophrenia, and four patients had deep insulin therapy for this misdiagnosed condition before the true nature of their condition was discovered. Recovery in the hospital usually took about a week, but as some of the patients were of unstable personality and some were addicts to one drug or another, relapse frequently occurred. Patients showed withdrawal symptoms in the form of depression and somnolence. The amphetamine groups of drugs are not as harmless as is generally supposed, and amphetamine psychosis appears to be more common than the literature would suggest. In all patients with acute or chronic paranoid schizophrenia the urine should be tested for the amphetamine group of drugs to avoid errors in diagnosis and treatment. These drugs should never be prescribed routinely for depression, fatigue, or obesity, and amphetamine psychosis should be borne in mind as a diagnosis.

Fees for Anesthesia in Hypnosis.—A physician can claim a fee for giving an anesthetic during childbirth if he is working in the national maternity medical service. The Minister of Health has now agreed to the payment of a fee for securing analgesia by hypnosis in maternity cases, provided the doctor concerned is accustomed to using hypnosis as part of his professional practice. The fee paid will be the same as if an ordinary anesthetic were used. A case arose in 1957 when a practitioner secured analgesia in childbirth by hypnosis but was refused a fee. The matter was referred to the local executive council and to the anesthetists group committee of the British Medical Association, which held that a fee should be paid under the circumstances. The Minister of Health has now agreed on a fee of $5.

Sensitivity to Penicillin in Poliomyelitis Vaccine.—British poliomyelitis vaccine contains 200 units per milliliter of penicillin. Although it has been considered by the Ministry of Health that this quantity is unlikely to do any harm, a general practitioner of Blackpool has reported a reaction, due presumably to the penicillin present, in a boy of 12 given the vaccine. The boy was already known to be penicillin sensitive, and a day after the vaccination he complained of frontal headache, malaise, and an urticarial rash on the trunk, limbs, and buttocks. An antihistaminic was given. Two days later the boy suffered from dyspnea, bronchospasm, and a tight feeling across the chest. This was relieved by a spasmolytic. In the physician's opinion the reaction was due to the penicillin in the vaccine.

Mycology of the Mouth.—Few attempts have been made to study the mycology of the mouth in relation to fairly common oral lesions. This was done by Fox and Ainsworth who inoculated slopes of malt extract agar with mouth scrapings from patients with various oral conditions and examined them for fungi (*Brit. M. J.* 2:826, 1958). If these developed they were transferred to pure culture and grown for identification. Scrapings from the mouths of normal subjects were also made. The oral mycology was investigated in 49 patients with angular cheilosis, gingivostomatitis, "coated tongue," lingua nigra, lingua geographica, and denture sores. It was concluded that Candida albicans plays a primary part in the cause of angular cheilosis and possibly of gingivostomatitis. The numerous other fungi isolated from the mouth of patients with the remaining four conditions were considered to be of doubtful etiological significance.

Fatty Acids.—Dr. H. M. Sinclair (*The Practitioner*, Oct., 1958) stated that the treatment of obesity allowing unlimited fat and restricting carbohydrate needs further investigation before it can be recommended to the public. High-fat diets in the United Kingdom mean diets high in relatively saturated fat and relatively deficient in essential fatty acids. He is also critical of the present method of feeding infants and children. Orange juice is not necessarily the best way of administering ascorbic acid; black currant juice would probably be a much better source. Cod liver oil is a bad vehicle for vitamins A and D in view of its absence of essential fatty acids and the presence of nonessential fatty acids that increase the need for essential fatty acids. Cow's milk, and particularly dried cow's milk, if exposed to air, is very inferior to human milk. Although the school meals and milk-in-schools schemes have improved the health and physique of schoolchildren and have played an important part in educating the children in good dietary habits, they have tended to overfeed the children, particularly with cow's milk and butter. Excessive feeding during the period of maturation is likely to lead to early maturity and to early death from chronic degenerative diseases. Excessive use of cow's milk and butter may lead to a deficiency of essential fatty acids.

There is no conclusive evidence that high serum cholesterol levels cause atheroma. On the other hand, there is evidence that a deposition of cholesterol occurs in various sites in the body through failure of the tissues to use the cholesterol they are forming because of a relative deficiency of essential fatty acid (a low ratio of essential fatty acid to nonessential fatty acid) in the tissues. This failure of the utilization and metabolism of cholesterol could cause a rise in serum cholesterol. Essential fatty acid seems to be required for fibrinolysis, which is essential for removing clots that regularly form intravascularly. Decreased fibrinolysis, perhaps also accompanied by increased coagulability of blood, could account for coronary thrombosis in the presence of atheroma. The rapid increase in reported deaths from pulmonary embolism and infarction, which is occurring at the same rate as deaths from ischemic heart disease, could be similarly attributed to a relative deficiency of essential fatty acid. This deficiency causes a structural defect in cell membranes and connective tissue, and in consequence the body becomes increasingly susceptible to injurious agents, including infections, ultraviolet light, x-rays, chemical carcinogens, and hydrochloric acid in the duodenum. It is possible therefore that a relative deficiency of essential fatty acid could play a part in the cause of coryza and poliomyelitis by allowing the virus to traverse the nasal and intestinal mucosa, and of leukemia, lung cancer, and duodenal ulcer.

Q Fever.—Marmion and Stoker stated that Q fever is widespread in Britain and is a cause of some cases of pneumonia and fever of unknown origin (*Brit. M. J.* 2:816, 1958). The infection occurs mainly through cattle and to a lesser extent through sheep. Rickettsia burneti was isolated from the milk of cows and goats, from the placenta and wool of sheep, and from the sheeptick. There was evidence of an increased frequency of infection in sheep and cattle in Kent. In this county the clinical cases occurred more in newcomers to the area, the residents of long standing being presumably immune. The chief mode of spread from cattle to man seems to be through the consumption of raw milk infected with the rickettsia. Milk may contain 5 to 500 guinea pig infective doses per milliliter. The author believed that more persons are not infected because the whey antibody in infected milk may afford some protection. The contact with the antibody-coated rickettsias leads to subclinical rather than clinical infection. In one area 7,000 to 8,000 persons were getting infected milk from two dairies. There were 94 cases of pneumonia among these, and it is estimated that about 30 were due to Q fever. Pasteurization at 161 F (71.7 C) for 15 seconds or 145 F (62.8 C) for 30 minutes kills the rickettsias. The authors showed that persons drinking pasteurized milk have a lower probability of contracting Q fever than those in the same area drinking raw milk. Infection was not limited to persons drinking raw milk or handling animals but was found in all sections of the community. Outbreaks occurred at any time of the year but were commonest between April and July.

Distribution of Physicians.—The medical profession in Scotland is now almost equally divided between general practice and hospital work (*Health Bulletin* 16:57, 1958). The relative figures are 2,890 in general practice and 2,886 in hospital work. This latter figure represents an increase of 30% in the last eight years. In Western Germany, the comparable proportions are 71% in general practice and 29% in hospital work.

Mental Patients in Hospital.—According to the annual report for 1957 of the Board of Control, which is responsible for the supervision of the mental hospitals in England and Wales, the number of patients in mental hospitals (146,962) was the lowest since 1949. On the other hand, the number of admissions is climbing steadily, and last year was 88,943, compared with 55,856 in 1950. Another striking feature of the report is the continued increase it shows in the number of voluntary admissions. In 1957, voluntary admissions increased to 82.6% (73,499) and certified cases fell to 15.9% (14,126). Of the total admissions in 1957, 41,908 (44.9%) were readmissions. Of the 82,778 patients discharged, 19,643 had recovered, in 54,054 cases the illness was relieved, and 8,822 showed no improvement.

Politics and the National Health Service.—In an age when treatment is complex and costly and when we expect equal care to be available for all, a national health service is an obviously efficient scheme, according to Sir Keith Joseph, a Conservative Member of Parliament, in an address to a Conservative Party Conference. He suggested that, as the Service grows and improves, there may be elements in it that can be charged to patients without discouraging early treatment or unduly burdening the ill. Such charges would be subject to a means test so that those least able to afford payment would be exempt. Contributions, too, could grow as average earnings grew. A graduated contribution, varying precisely with earnings, would have to take personal circumstances into account and would quickly become a second tax system.

He foresaw an inevitable increase in the cost of the Service, and this would include increased remuneration for physicians. He believed that the general practitioner should be freed from the economic necessity to maximize the number of his patients, regardless of the actual constructive treatment he is willing or able to give them. He said that private practice should be encouraged and that more physicians should depend on it for part of their living. It is not good for doctors to have only one possible employer—the government; yet this would be the result if private practice were to die. The chief argument against private practice is the allegation that two standards of service would result.

Sexology and Medical Students.—At their annual meeting last year, the British Medical Students' Association held a half-day symposium on the teaching of sexual and marital relations to medical students. This subject was chosen because both students and physicians believed that these subjects are often taught inadequately, if indeed they are taught at all. A report of the proceedings shows that attention was almost equally divided between the necessity for helping students to solve their own sexual problems and instructing them to deal with the similar problems of their future patients. According to one speaker, in the case of a medical student, the study of anatomy and physiology induces a mechanistic approach to matters which are primarily spiritual and psychological. The student whose sex education has been inhibited or distorted by his home background can get into serious difficulties, for he may already have severe emotional tensions when he arrives at the university. It was concluded that (1) the teaching in this field is inadequate in many medical schools, (2) the creation of a new department is not necessary, (3) proper teaching must be available, (4) libraries must have a wide selection of literature on these topics, and students must be made aware of them, and (5) the most important factor of all is to help each student to solve his own problems as they arise.

Health Problems of Directors.—The Institute of Directors has published a booklet, "Health Problems of Directors," in which Dr. H. B. Wright, the head of the institute's medical research unit, tells directors how they can live longer and happier lives. On the subject of vacations, W. J. Mayo said that he was of more use to his clinic steering his yacht than sitting at his desk. Every director should have two vacations a year, and it is contended that much could be gained if senior executives worked a 10-month year of 40-hour weeks. Although alcohol is a poison, in moderation it is recommended, but with several warnings. The cocktail party is a diabolical institution, and the wise executive should curb the present tendency to regard cocktail parties as an official necessity. If he must go to one, he should dilute the alcohol—gin and tonic, whisky and soda, or beer is far less harmful than a martini.

Those who travel abroad are advised to go by boat one way, if possible. Airplanes may be convenient but they are most unphysiological. A slumberette may look good in an advertisement but in reality very poor sleep is the best that can be expected. The executive is advised to try not to work in the aircraft and to try to insist on 24 hours without official functions on arrival at his destination. To rush off the aircraft to the first cocktail party is folly. While on tour, he is advised to insist on at least an hour and a half a day to himself and, if the tour is prolonged, to insist on a five-day week and every fifth week off entirely. Finally, it should be a rule that every executive returning by air should have 48 hours off at home. If he must report to work immediately, he should allow half a day for this and then have the time off.

The Normal Color Index.—Using an automatic red blood cell counter and a Medical Research Council photometer, J. C. F. Pool (*Lancet* 2:550, 1958) measured the color index in 24 normal subjects. He found the mean color index to be 0.99, and the coefficient of variation for the series was 4.93%. The standard error of the mean was 0.0099. The fact that the color index for normal human subjects is so close to unity, when determined in this way, is a fortunate coincidence. In the author's opinion there is no advantage in reporting the ratio of the hemoglobin content to the erythrocyte count as weight of hemoglobin per cell (mean corpuscular hemoglobin) rather than as the color index. Because of the small range of normal color-index figures, it is hoped that small deviations from the normal, which can now be detected reliably, may prove significant indications of disease.

Antivaccinal Gamma Globulin.—Details of the successful use of gamma globulin prepared from the serum of recently vaccinated adults are reported by E. R. Peirce (*Lancet* 2:635, 1958). The two persons in whom it was used had been in contact with a severe case of smallpox in their home for nine days. One was the patient's sister, aged 6 and unvaccinated, and the other was his grandmother, aged 73 and unvaccinated since infancy. Both were vaccinated, with the other family contacts, on April 14, the day on which the patient, who had taken ill on April 6, was diagnosed as having smallpox. Two days later they were given gamma globulin, the child receiving 2 Gm. and the grandmother 1 Gm. On April 21, both child and grandmother developed smallpox but both had mild cases, so mild that in the case of the child had she not been under daily supervision her smallpox would not have been recognized. Although both were successfully vaccinated, it is considered that, in view of the timing, this is unlikely to have had any effect on the course of the disease and that the mildness of the disease in both cases was due to the gamma globulin.

Antibiotics in Acute Tonsillitis and Otitis Media.—Dr. Fry investigated the need for antibiotics in the management of acute tonsillitis and acute otitis media on the supposition that not all of these infections require such specific measures (*Brit. M. J.* 2:883, 1958). Over a three-year period he treated 482 attacks of acute tonsillitis in 405 patients and 552 attacks of acute otitis media in 422 patients. Penicillin, the antibiotic used, was withheld unless there were definite indications for its use. The course of each patient was followed carefully, and there was no hesitation in giving penicillin when it was needed. This occurred in 25% of all attacks of acute tonsillitis—19% in the nonstreptococcic group and 30% in those in whom hemolytic streptococci were found in the throat swabs. In the treatment of acute otitis media, antibiotics were needed in 22% of the patients. They were given in 15% of those with painful eardrum and 34% of those with a discharging ear. The results in both the groups treated with and without antibiotics were satisfactory. No serious complications occurred in either group, and on follow-up three months later only three children were found to be slightly deaf. There were no discharging ears, and recurrences were uncommon. Fry stated that 70 to 90% of patients with tonsillitis and otitis media are treated with antibiotics in general practice, and from his findings he questioned whether this extensive use is necessary. Antibiotics are relatively expensive drugs and not without danger.

Nursing Routine Challenged.—The end of 5 a. m. awakening of hospital patients is in sight. This traditional and unpleasant feature of hospital life has been shown to be unnecessary. Its purpose is to enable patients and wards to be ready for doctors' rounds at 9 a. m. or later. There may yet be opposition to changing the practice from sticklers for the old ways. Nurses are increasingly questioning the need for rousing patients at the traditional time and taking their temperatures at six, and the necessity for a busy ward nurse to stand for hours at the side of a consultant on his teaching rounds while he asks the same questions of successive generations of students. The recent reduction of nurses' hours from 48 to 44 hours a week has sharpened the arguments against extraneous duties and wasteful ways of working, especially where a shortage of nurses exists.

Evaluating General Practice.—Recently a group of Conservative Members of Parliament recommended that general practitioners be divided into grades for purposes of remuneration, based on their respective abilities. Dr. Donald Johnson, who is also a Conservative Member of Parliament, foreseeing difficulties asked how, without direct payment between patient and doctor, which is precluded by the present structure of the National Health Service, the good physician can be judged against his less good colleague. Who will judge the worth of the physician and what will the criteria of judgment be? A medical administrator is likely to see excellence only in administrative qualities. It would be undesirable if a good doctor were judged solely by his attention to record cards and his compliance with administrative instruction.

Doctor as Subpostmaster.—The subpostmasters at South Shields, Durham, are objecting to the choice of Dr. Henry Byrne, a police surgeon, as a subpostmaster when three experienced applicants were rejected. Dr. Byrne said: "My wife will supervise the post office, and I shall assist when necessary. I am sure we shall be able to give good service to the public. I do not intend to withdraw." A spokesman for the local branch of the British Medical Association said: "What a doctor does is his own affair, as long as he looks after his patients and does not offend the health executive council. Why he should want to become a subpostmaster I cannot imagine. I have been playing golf today, and everyone has been asking me if I can sell them a twopenny stamp."

Radiation Hazards.—The suggestion that present assessments of the genetic hazard to man of nuclear and allied radiations may prove false was made at a small conference in London. Dr. T. C. Carter, of the Medical Research Council's Radiobiological Research Unit, believes that, hitherto, research on the effects of radiations on living material has been made almost entirely on the lower animals and on plants, which can stand much larger doses of radiation than can be tolerated by man. From these experiments it has been assumed that the genetic danger from radiation increases directly as the dose increases, but in a critical analysis of the evidence from the few experiments made with small doses, within the range tolerated by man, Dr. Carter showed that this assumption is not justified. He estimated that the necessary research would require about 2,650,000 mice and take over five years at a cost of about $560,000. The importance to mankind for reliable data on the dangers from radiation to future generations cannot be overemphasized.

BUSINESS PRACTICE

This is the ninth in a series of excerpts from the brochure on the Business Side of Medical Practice, prepared by the American Medical Association in cooperation with the Sears-Roebuck Foundation.

BILLING AND COLLECTIONS

Income is what keeps a doctor in practice. How can he guarantee that he will receive the greatest percentage of fees he earns? Once again, the principles of good management apply: advance planning, an established routine, and adherence to that routine.

Here are three keys to maintaining a high collection ratio: 1. Make certain patients understand charges and appreciate they are getting professional service commensurate with the fee. 2. Make it convenient for patients to pay at time of treatment. 3. Send bills punctually and regularly; follow up conscientiously on uncollected bills.

Advance fee discussion is the best means of assuring that patients understand and accept their medical bills. Because people subconsciously resent paying for an unwanted illness, a certain amount of ethical "selling" of the concept of regaining and maintaining good health is advisable. The importance of reaching agreement and understanding about fees in advance of long or costly treatment was discussed earlier and some techniques for initiating fee talks suggested. The patient is entitled to know what to expect—he ought to be forewarned when he is sent for x-rays and other laboratory tests that show up as a sizable figure when his statement arrives. He is buying medical service, and he wants to know approximately what it will cost, just as he wants to know how much a new suit of clothes or a new purchase for the home will cost.

Explaining Charges

The best way to explain medical charges is to itemize each bill. This has been standard practice in the business world for years, yet too frequently physicians send statements merely saying, "For professional services." The doctor himself would be annoyed to receive a bill from a medical supply house which said only, "For supplies shipped," and he should keep this in mind in his own billing.

Patients may forget how many office or hospital calls were made in the interval before the bill was sent and overlook the extent of services given. On the surface, an unitemized bill may appear to be excessive. Today there are simple procedures for itemizing bills. The charge slip is a form widely used. This is a slip usually kept in triplicate which, depending on the doctor's specialty, lists the various types of services he performs.

The patient is given a charge slip to take into the doctor's office with him. During his session with the patient, the doctor notes on the slip the procedures performed and the charge. As the patient leaves the office, he returns the slip to the desk. At this point, instead of the doctor's girl saying, "Would you like to pay for your visit now?" it might be more effective merely to say, "This will be $5." Most people are prepared to pay for routine office visits but often leave the office without paying because no one gave them an opportunity to do so. If most patients can be encouraged to pay as they go, expensive, time-consuming billing can be reduced.

The patient who pays before he leaves the office is given one of the charge slips as a receipt; the others serve as office records. When a patient prefers to be billed, the charge slip is used to prepare an itemized bill or a copy is actually enclosed with the statement. Some physicians are microfilming the information on the charge slip onto the monthly statement. In addition to serving as an itemized listing of services performed, the charge slip provides a check for the office should a patient later question a bill.

Regular Billing

Some definite pattern for sending out statements should be established early in a doctor's practice. Regular billing is an essential part of good collection procedure. Punctuality in billing encourages prompt payment. A doctor who sends bills erratically, perhaps allowing several months to elapse before mailing a statement, must expect his patients to treat their payment responsibilities similarly. It is natural for the patient to think: "If the doctor doesn't attach much importance to the bill, then I won't either." The longer payment is delayed, the harder it is to collect.

Some physicians prefer to send out bills once a month; others mail statements twice a month—on the 1st and 15th. Some follow a cyclical billing system used in businesses, whereby statements go to patients in certain sections of the alphabet on certain dates each month. The kind of billing system is not so important as the fact that the doctor has a system and follows it.

Regular billing and itemization of charges pave the way to easy collections. It also helps if the doctor makes it easier for patients to pay by enclosing a return business reply envelope and clearly specifying the date on which payment is due.

All these things can be done in a dignified, professional manner which does not imply commercialism if the physician puts the business side of his practice in the proper perspective, remembering that his first job is to care for his patients.

Following up on Collections

When regular itemized statements have been sent and payment has not been received, the physician should initiate his collection follow-up program. This program should be based on an understanding of some of the reasons why patients don't pay. There are a number of them, but these three probably are the most common: (1) negligence, (2) inability to pay, and (3) unwillingness to pay.

When a patient merely puts off payment with no good reason, the physician himself may be partly to blame. He may not have sent his bill promptly, or he may not have jogged the patient about his financial responsibilities. Many people tend to pigeonhole their doctor bills, postponing payment until their other debts have been paid. Physicians themselves must educate the public to treat medical bills as they do any other kind of indebtedness—paying what they owe when it is due. If the doctor ascertains that negligence is the reason he has not received payment, he can institute his plan for reminding the patient about the bill.

Some patients who would like to pay sometimes are temporarily unable to do so. If this is the case, the physician should be prepared to understand the situation and help patients make other arrangements, even to budgeting a certain amount each month for the doctor's bill. Time-payment buying is now widely accepted by the public; there is no reason that in special situations or in cases of temporary financial hardship it cannot be applied to the purchase of medical services. Although businesses offering time-payment plans add carrying charges to the bill, this is rarely done in medicine. Because the medical profession is humanitarian in tradition, special approaches to collections which would not work in the "hard, cold, business world" are applied. The physician who stands in the position of a friend to his patients wants to help the individual meet his financial obligations. Interestingly enough, the honest patient who does not pay often seeks out another physician because his pride does not permit him to return again and again to the office where he owes money.

Some patients are unwilling to pay. These individuals may be disgruntled about the bill. Perhaps the misunderstanding was partly the doctor's fault. In this case, an attempt to talk over the situation with the patient is the first step toward eliciting payment. Only in rare instances are patients deadbeats who just do not intend to pay. It is this type of patient who causes the doctor to give serious consideration occasionally to resorting to a tougher collection policy, even to instituting suit.

Considering the factors affecting nonpayment, the physician starts collection procedures to (1) remind the negligent patient about his bill, (2) inquire why payment hasn't been made—is there some special reason for nonpayment? and (3) get patients who have a reason for nonpayment into the office to discuss the problem and work out a solution. Getting adequate credit information in advance helps the physician evaluate a patient's financial situation.

Good records are essential to follow-up collections, so the medical office must secure the following information about new patients on their first visit: (1) full name, correctly spelled; (2) proper person to be billed and relationship to patient; (3) marital status and number of dependents; (4) current address and past addresses for last two or three years (indicates stability, neighborhood, and index of financial status); (5) job details (where a man works is important; what he does is even more vital); and (6) name of person recommending patient.

Such information can be secured quickly and with no affront to the patient. In some offices inquiries are made about patient's charge accounts, since these are good credit indexes. It is poor policy to ask about banks and bank accounts. Superficial signs of prosperity should not color an evaluation of the patient's financial status. When a substantial sum is involved and there is some question, the credit rating can be checked with the local credit bureau. Obviously, it's easier for the doctor in a small town to gauge his patient's ability to pay than it is for a city physician.

Collection Timetable.—Every physician will want to work out his own "collection timetable," but here is one which works for many doctors: first month, send statement; second month, send statement; third month, send a reminder note; fourth month, send a letter; and fifth month, write the patient notifying him that, since he has ignored all communications, the account is being turned over to a collection agency.

The personal approach is the best way to follow up collections. That's why stickers and other commercial devices attached to statements are not always highly effective. After two statements have been sent, a short note from the doctor or his secretary can be sent inquiring whether the patient has overlooked the bill. The letter might read like this: "We thought perhaps you may have overlooked this statement which has been charged to your account since . . ."

The next letter, preferably a letter from the doctor, should invite the patient to the office to discuss any special payment problems or questions he may have about the bill. Whatever kind of reminder is used, it should be informal, sincere, and imply confidence that the patient does intend to pay. Avoid all "pleas," such as "I need the money" and "I have bills to pay, too."

The final letter may imply surprise that the patient has made no response to collection overtures and request once more that the patient get in touch with the office to discuss the situation. If this is ignored, a more formal letter notifying the patient that the account is to be turned over to a collection agency can be sent.

A physician should not be embarrassed about following up on bills that are justly owed him. As his practice develops, an intelligent, efficient girl can handle most of the collection phase of his practice, clearing up many misunderstandings about charges and serving as a good will ambassador.

In every community collection practices differ. Sometimes the doctor carries a credit load until crops come in or some other seasonal source of income develops. This does not mean he discontinues billings during "off seasons" but instead lightens his collection pressures, bearing down during the time patients have money.

The older a bill becomes, the less likely it will be paid. Accounts over a year old seldom return more than 45 cents on the dollar—those two years old, 23 cents. After three years the return is 15 cents on the dollar, and after five years it wouldn't buy a postage stamp. That's why collections should be pursued diligently while the accounts are "fresh."

Often a physician is faced with a decision regarding a bill: should he reduce it or cancel it entirely? Sometimes a patient who has owed him money for many months offers to settle in cash if he will discount the bill. If the charges were correct in the first place and the patient is financially able to pay the entire amount, the wise doctor will not submit to the temptation of accepting the discounted bill. He may soon get a reputation for discounting or "bargaining" for his services.

There are two prevailing philosophies on the question of whether to reduce or cancel a bill entirely in a hardship case. One idea is that a doctor should reduce but not cancel the bill in order to save the patient's pride. The other philosophy is that a doctor should never reduce but should completely cancel a fee, evolving from the belief that no doctor should bargain for his services. The decision to reduce or cancel a fee rests with the personal philosophy of the physician.

Using a Collection Agency

When the doctor has made an earnest effort to collect his own bills and still has not received payment, he may wish to employ the services of a professional collection agency. There are many agencies which specialize in the handling of medical and dental accounts or which have separate departments to handle this type of collection. In some places medical societies operate their own bureaus.

An ethical agency can serve a physician well, prodding the people who can pay, but do not, into settling their debts and uncovering instances where special consideration is warranted. Medical collections call for a different approach than do collections in other businesses. That is why selection of a reputable agency is the physician's first consideration. It is usually best to select a local agency with a good reputation in the community and avoid out-of-state or mail-order-type agencies. Here are some guides in selecting a good agency: 1. Check with the local medical society whose officers probably can give information on the reliability of an agency. 2. Check with the local chamber of commerce or Better Business Bureau. 3. Check with such groups as the medical, dental, and hospital bureaus of America, or the Associated Credit Bureau of America, whose members conform to high standards of operation. 4. Check up on the ownership and financial responsibility of the agency and its promptness in settling for money collected. 5. Find out the kind of collection methods. Ask to see the type of reminders and follow-up pieces used. 6. As a general rule, don't sign a contract. Good agencies seldom use them.

Any physician who is asked to sign a contract in the employing of an agency should proceed cautiously, since there are sometimes traps in the contracts of less reputable agencies which can not be quickly spotted. They may call for payment in worthless bonds instead of cash or withhold any settlement "until the bill has been collected in full," a rare instance in the handling of delinquent accounts.

The Agency Works for You.—The agency is at all times the collection representative for the doctor. The procedures and techniques used in following up his accounts should conform with the ethics and dignity of the profession, and the doctor himself must have the final say on disposition of accounts. It should be the decision of the doctor, not of the agency, for example, whether legal action should ever be taken. A good agency also should be willing to adjust a fee in a hardship case rather than try to boost its own commission by a cold pursuit of the total amount due.

The physician must provide all necessary information to the agency, including basic data from the patient's nonclinical record and a report on his follow-up actions. When the agency takes over an account, the doctor ceases all billings to the patient. If the patient then calls the doctor to discuss the bill, he should be referred courteously to the agency. Any payment made directly to the physician should be reported to agency officials; if it was secured after their collection efforts began, the agency is entitled to a portion of it.

Medical bills turned over for collection to an agency are discounted, and the older the account the greater the discount. Any return is better than none at all. The average cost of collecting medical fees is about 40%, but this rate varies according to individual agreements and local situations. In one city, the average collection on delinquent accounts is 10%. When the doctor employs an agency, he is employing skilled men in the collection field and he must expect to pay for their services. However, when collections rise beyond 25%, it is usually a clear indication the doctor's own office is not doing its part in pursuing collections.

Should You Sue?

Suing to collect a bill is a drastic step that sometimes is offset by the resultant ill will it creates. A vengeful patient—justly or unjustly—may sometimes file a malpractice suit countering the doctor's collection suit. Consequently, many physicians delay any legal actions until after the statute of limitations determining the extent of time during which a malpractice action can be filed expires. This period varies from state to state.

A lawyer is the best person to judge whether or not a physician has a chance of collecting in court. Points to consider are the clear rights of the claim, the patient's ability to pay, exhaustion of other collection means, and justification of the amount by comparison with fees for similar services locally. In more than half of the states and in the District of Columbia doctors may act as their own lawyers in small claim courts—where sessions involving debts usually under $100 are held. The doctor merely presents his claim to a judge after paying a fee of $1 or $2 for a summons to the patient. A small claims court in New York is credited with winning suits for nine out of ten physicians but this doesn't mean those physicians collect. Enforcement of the legal claim is not always carried out.

In all collection efforts, a balance of humanitarianism and firmness seems to get best results.

MEDICAL FILM REVIEWS

A Clinic on Recognition and Management of Respiratory Acidosis: 16 mm., color, sound, showing time 34 minutes. Prepared by Reginald H. Smart, M.D., Hurley L. Motley, M.D., and Joseph F. Boyle, M.D., Los Angeles. Produced in 1958 by Churchill-Wexler Film Productions and Ed Hamilton Productions, Los Angeles, for and procurable on loan from Smith Kline & French Laboratories, Medical Film Center, Philadelphia 1.

This film is based on a televised clinic originally presented at the 37th meeting of the College of Physicians, Los Angeles, 1956. The course of a fatal case of respiratory acidosis is illustrated and discussed by the authors. Etiology and symptoms of this condition are examined in detail, and the importance of early recognition is emphasized. A suggested treatment program, including emergency treatment of acute cases, is outlined fully and includes demonstrations of various types of respiratory equipment. One of the chief values of this film is the dramatization of the danger of oxygen therapy in the presence of hypercapnia. In this way, many ideas are conveyed with lasting impact that could not be transmitted by the didactic approach alone. On the other hand, the pathophysiology of respiratory acidosis is well discussed with the use of helpful color charts. The determination of arterial blood pH is stressed; however, it should be remembered that an elevated arterial carbon dioxide concentration is a more specific pivotal factor in respiratory acidosis. There are minor omissions, such as carbonic anhydrase inhibitors. The physician viewing this film should bear in mind that it is probably better to give oxygen to a patient with cyanosis and watch his response to it rather than to withhold oxygen while waiting for respiratory equipment. This teaching film is highly recommended for house officers, visiting staff, and medical students.

Retropubic Prostatovesiculectomy: 16 mm., color, sound, showing time 10 minutes. Prepared by McCleery Glazier, M.D., and Louis J. Lombardo Jr., M.D., Los Angeles. Produced in 1957 by Billy Burke Productions, Hollywood. Procurable on loan from Eaton Laboratories, 17 Eaton Ave., Norwich, N. Y.

In this motion picture the operative technique of retropubic prostatovesiculectomy is demonstrated on a cadaver. The procedure is shown in detail and the advantages of the retropubic approach, particularly the excellent surgical exposure it affords, are pointed out. The author's technique for this procedure is primarily used for the surgical treatment of early prostatic carcinoma. Models are used at the beginning and end for orientation. It is an excellent film and is recommended especially for residents, interns, and urologists. It would also be of interest to general surgeons and surgical nurses.

ILLUSTRATED FILM REVIEWS

A CLINIC ON RECOGNITION AND MANAGEMENT OF RESPIRATORY ACIDOSIS

Reginald H. Smart, M.D., Hurley L. Motley, M.D., Ph.D.
and
Joseph F. Boyle, M.D., Los Angeles

Each day in hospitals in the United States, deaths due to respiratory acidosis occur among patients seen in all fields of medical and surgical practice. Although certain clinical signs should alert physicians to the presence of this condition, all too often it is unrecognized. Because these patients die a chemical death, autopsy will not demonstrate the cause. However, before death, simple, accurate laboratory procedures can be performed which will quickly establish the diagnosis and permit effective treatment. These should be available in every hospital. A brief study of the pathological physiology involved demonstrates the pathogenesis of this condition and provides the basis for prompt recognition and proper treatment. Effective therapeutic measures are available, and, *if respiratory acidosis is recognized and adequate treatment instituted in time*, the majority of these patients' lives can be saved. The written review of this film appears on page 2053 of this issue. (This film is sponsored and distributed by the Medical Film Center, Smith Kline and French Laboratories, Philadelphia 1.)

Fig. 1.—Oxygen plays lifesaving role in many instances. However, when injudiciously or improperly used, it may become instrument of death.

Fig. 2.—Case of death due to unrecognized respiratory acidosis is reviewed by attending staff and resident physician.

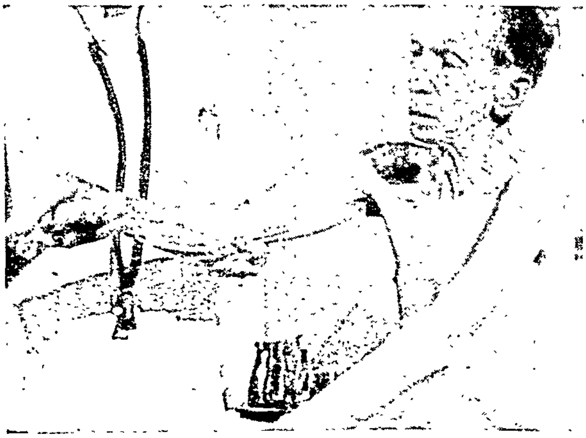

Fig. 3.—On admission to hospital, patient was dyspneic, cyanotic, and agitated. Resident ordered meperidine (Demerol) hydrochloride.

Fig. 4.—After injection, oxygen was given by mask. Cyanosis disappeared, but patient became comatose and died.

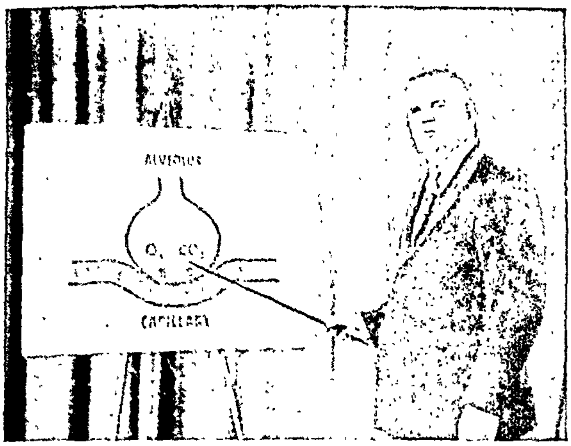

Fig. 5.—Resident suspected cerebral vascular accident, but autopsy revealed only some bronchitis and emphysema. Review of respiratory physiology explains what happened.

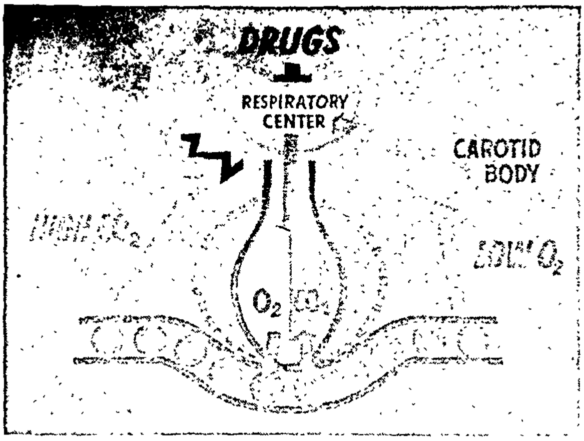

Fig. 6.—Normal response of respiratory centers can be depressed by *excessively high concentrations* of blood carbon dioxide, also by administration of barbiturates or opiates.

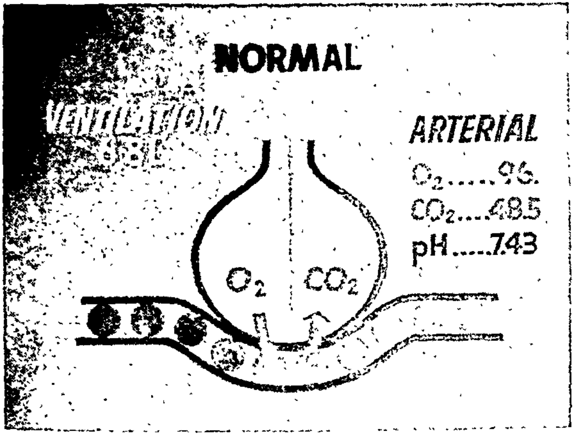

Fig. 7.—Changes in ventilation are best studied by examination of arterial blood.

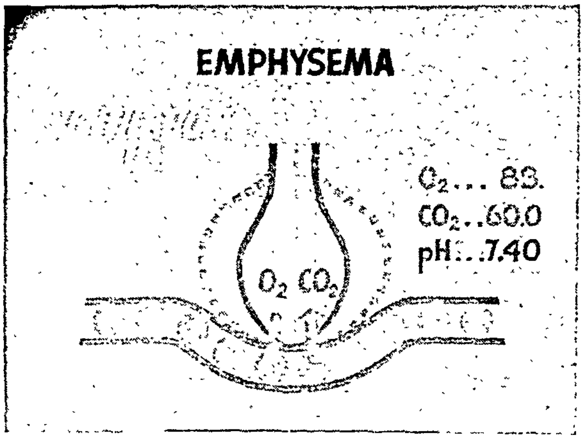

Fig. 8.—Decreased alveolar ventilation results in diminished elimination of carbon dioxide and decrease in arterial oxygen saturation.

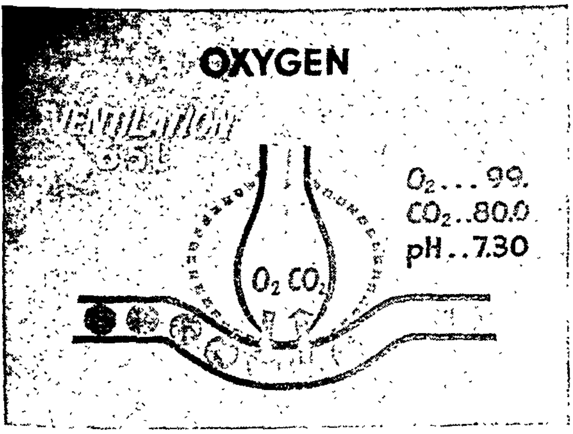

Fig. 9.—If oxygen is administered, blood becomes saturated with it and hypoxic part of stimulus to breathing is eliminated. Ventilation decreases further, more carbon dioxide accumulates, and pH falls. This is respiratory acidosis.

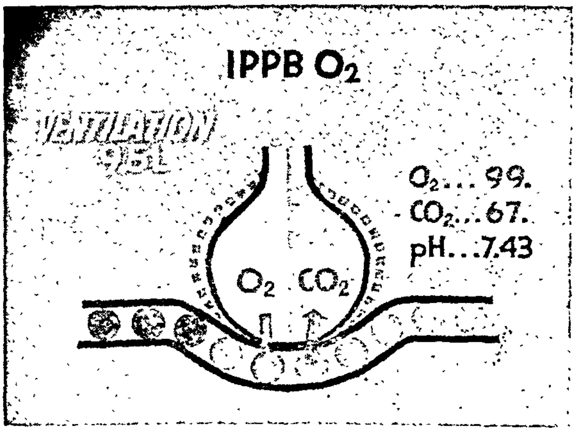

Fig. 10.—If oxygen is administered with intermittent positive pressure, the blood becomes saturated with it, alveolar ventilation is improved, carbon dioxide is better eliminated, and pH returns to normal.

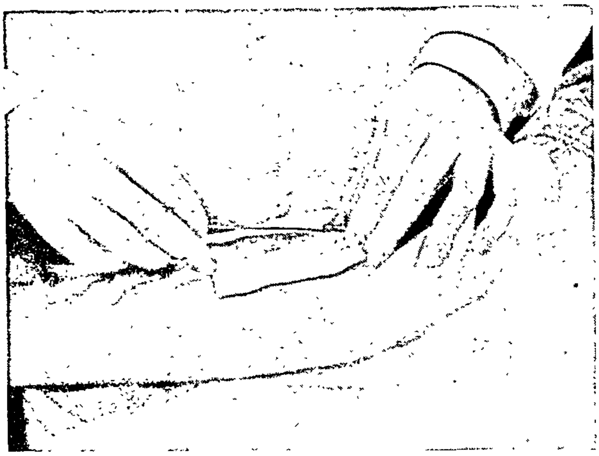

Fig. 11.—Arterial blood, not mixed venous blood, must be used. There should be intermittent spurt to verify puncture of artery.

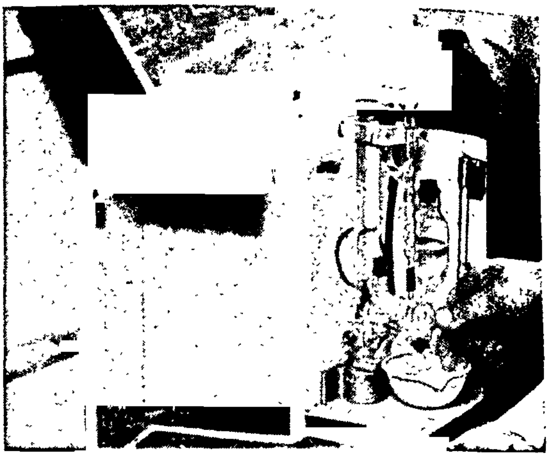

Fig. 12.—Arterial blood pH determination, with glass electrode pH meter, quickly and accurately confirms diagnosis of respiratory acidosis.

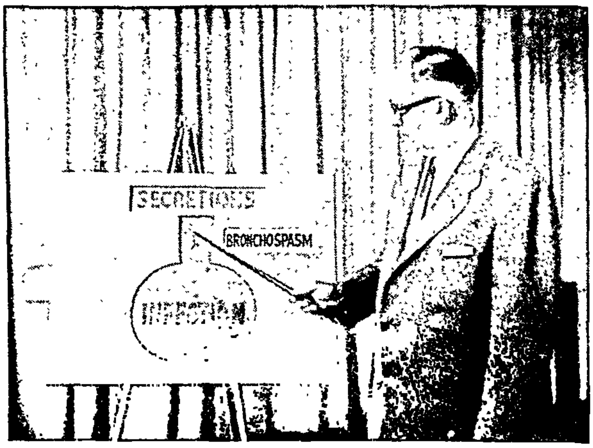

Fig. 13.—First principle of therapy is to remove obstructions to adequate airway.

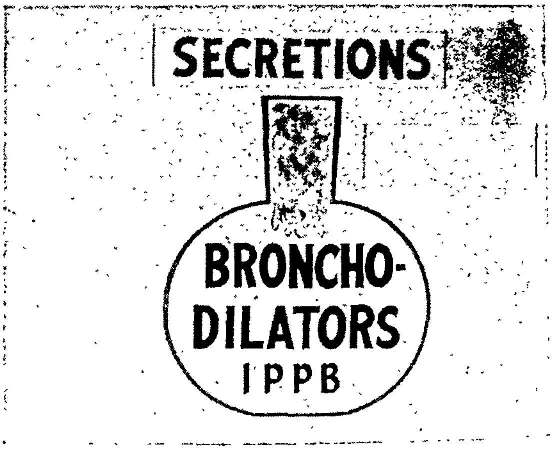

Fig. 14.—Bronchodilators and antibiotics are administered best as aerosols, and with intermittent positive-pressure breathing medicaments are carried down to areas where they will be most effective.

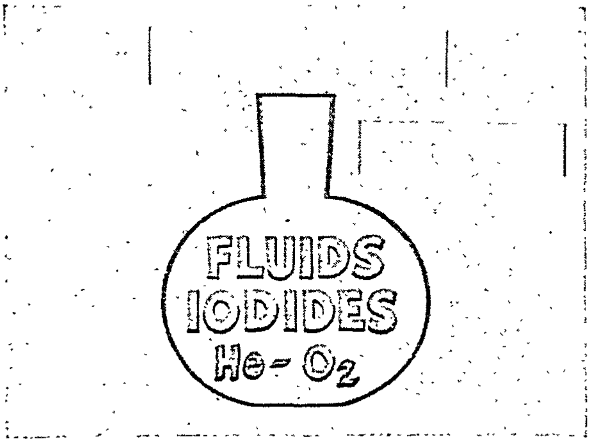

Fig. 15.—60-40% helium-oxygen mixture will improve ventilation, will carry aerosol beyond obstructing mucous plugs, and leaves inert gas with which to expel secretions and prevent atelectasis.

Fig. 16.—Another principle is to improve distribution of air in lungs and thereby augment alveolar ventilation. This can usually be done with intermittent positive-pressure breathing therapy.

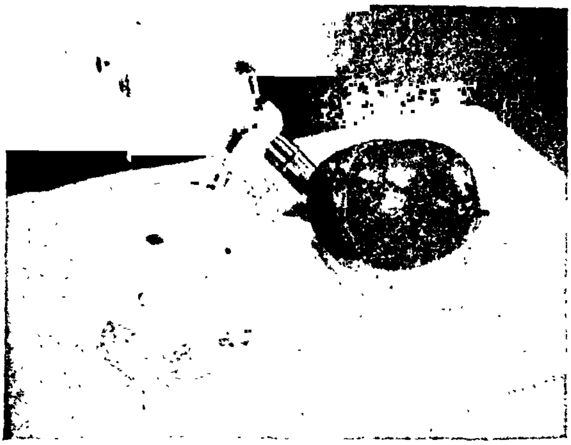

Fig. 17.—With two balloons representing alveoli, positive-pressure breathing is demonstrated effectively to overcome inadequate alveolar ventilation and improve distribution of air to otherwise poorly ventilated alveoli.

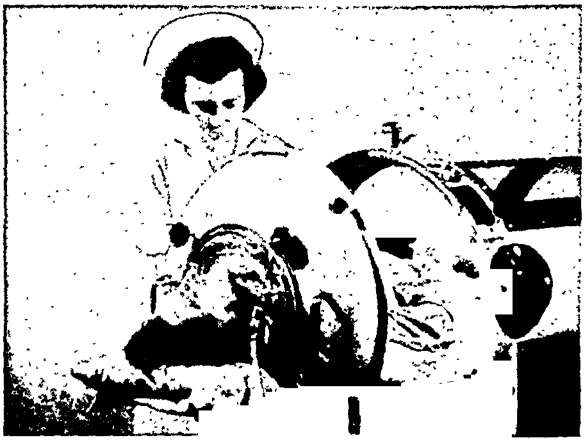

Fig. 18.—If patient cannot be ventilated adequately with portable equipment, it may be necessary to use iron lung.

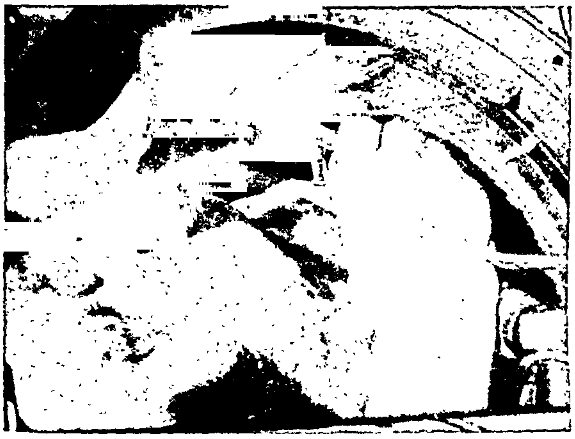

Fig. 19.—Some patients require tracheotomy to allow better aspirations of secretion and reduce "dead space."

Fig. 20.—In two or three days, this man was well enough to be taken out of respirator. In several weeks, tracheotomy tube could be removed.

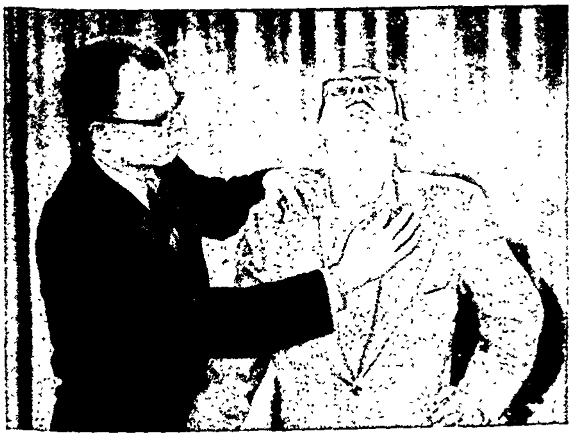

Fig. 21.—Another patient became apneic after receiving sedatives and oxygen. He was ventilated with pressure breathing through tracheotomy tube.

Fig. 22.—It was several days before he was able to breathe on his own, but he recovered, returned to work, and has had over three years of comfort.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Lung Cancer Death Rates in England and Wales Compared with Those in the U. S. A. E. C. Hammond. Brit. M. J. 2:649-654 (Sept. 13) 1958 [London].

The lung cancer death rate reported by the Registrar General for England and Wales in 1955 was 69.3 per 100,000 population for males and 10.6 per 100.000 population for females. Standardizing the lung cancer death rates reported by the National Office of Vital Statistics for the United States in 1955 to the age distribution of the population of England and Wales in 1955, the rates were only 33.0 per 100,000 population for males and 6.7 per 100,000 population for females. Thus, the lung cancer death rate reported in England and Wales for males was 2.1 times as high as that reported in the United States, and for females it was 1.6 times as high. A difference of this order of magnitude has existed in the male rates for several decades, while before 1949 there was only a small difference in the female rates.

Among both men and women in the middle-age and old-age groups there are proportionately more cigarette smokers in the United Kingdom than in the United States. On the other hand, at the present time the number of cigarettes consumed per smoker per day is higher in the United States than in the United Kingdom. The proportion of male cigarette smokers who inhale appears to be approximately the same in the 2 countries. In the United States the average length of the remaining butt after a cigarette is discarded is about 31 mm.; about 5% are 45 mm. or longer, and about 9% are under 20 mm. in length. In the United States in 1957 the main stream smoke of the average cigarette contained about 2.6 mg. of nicotine and 42.8 mg. of tar. More recently, cigarettes with a relatively low content of nicotine and tar have become increasingly popular in the United States. Data at present available do not support the hypothesis that a substantial proportion of the difference in lung cancer death rates between the United Kingdom and the United States is attributable to differences in the use of cigarettes. However, more detailed information on smoking habits and on the chemical composition of cigarette smoke in the 2 countries is needed before this can be definitely established.

In both the United Kingdom and the United States the lung cancer death rate of smokers, as well as the lung cancer death rate of nonsmokers, is higher in urban areas than in rural areas. The difference in this respect is reported to be far greater between a large city such as Liverpool and rural areas of Wales than between large cities and rural areas in the United States. However, Merseyside (which includes Liverpool) has a higher male lung cancer death rate than any other region in England and Wales, and so it cannot be considered as typical of the country as a whole. While it is possible that some of the difference in lung cancer death rates may be due to factors associated with urbanization—for example, air pollution or occupational exposures—available evidence does not suggest that these factors can account for a large part of the difference. The reported death rate from cancer, exclusive of lung cancer, declined steadily from 1931 to 1956 in England and Wales but rose slightly in the United States during the same period of time. It is possible that differences in the diagnosis and the recording of causes of death may account for a part of the difference between reported lung cancer death rates in the 2 countries.

Myxedema, Pseudomyotonia and Myotonia Congenita. L. W. Jarcho and F. H. Tyler. A. M. A. Arch. Int. Med. 102:357-366 (Sept.) 1958 [Chicago].

A 39-year-old housewife was hospitalized in the 8th month of her 8th pregnancy for prenatal care. She gave a history of goiter since the age of 15, intermittently treated with iodine. Neither thyrotoxicosis nor hypothyroidism was suggested by her history, but during her 6th pregnancy, 9 years previously, she had complained of "strangling" sensations, apparently related to growth in size of the gland. Symptoms subsided on treatment with strong iodine (Lugol's) solution. A year later, because of the appearance of a nodule in the cervical mass, slight neck tenderness, and difficulty in swallowing, a subtotal thyroidectomy was performed. An estimated 3 Gm. of the right lobe was left in situ, and the remainder of the gland was removed. Ten hours after surgical intervention the patient

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1949 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

showed typical signs of postoperative hypoparathyroid tetany, and myxedema developed two months later. Simultaneously the symptoms and signs of generalized myotonia were manifested, and electromyographic studies confirmed the diagnosis. This disorder has been differentiated from pseudomyotonia, a common feature of myxedema, and from other muscular affections occasionally seen in hypothyroid patients. Hormonal therapy greatly improved but did not entirely correct myotonia in this patient, and the effect of treatment was not sufficient to alleviate myxedema.

True myotonia was identified in 3 blood relatives of the patient and was probably present in at least 3 others, none of whom showed symptoms or signs of thyroid dysfunction. The family, therefore, appears to be affected by congenital myotonia. The condition was manifested in a mild form in the patient reported, being temporarily aggravated by myxedema. Several members of the family showed a hereditary abnormality of the skin, hyperkeratosis palmaris et plantaris. The frequent occurrence of this skin disorder in subjects with myotonia suggests that it may have a hereditary linkage to myotonia in a group of blood relatives.

Postoperative Myocardial Infarction: Report of 35 Cases. G. Feruglio, S. Bellet and H. Stone. A. M. A. Arch. Int. Med. 102:345-353 (Sept.) 1958 [Chicago].

Myocardial infarction is not an uncommon postoperative complication; it is particularly prevalent in the older age group. Thirty-five patients with postoperative myocardial infarction were selected from 21,000 patients who were subjected to surgery in the last 3 years. Twenty-two patients were men, and 13 were women. Their ages ranged from 43 to 83 years, with an average of 69 years. The electrocardiographic diagnosis obtained before surgery in 30 patients of this series was within normal limits in 7; there was slight myocardial abnormality in 10 and moderate to severe grade of myocardial abnormality in 13. Most of the patients (24) underwent major abdominal surgery. These operations were performed with the patients under the following types of anesthesia: local anesthesia (topical and infiltration) in 6 patients; spinal anesthesia with supplementation (tetracaine [Pontocaine] hydrochloride or dibucaine [Nupercaine] hydrochloride) in 3; and general anesthesia (thiopental [Pentothal], cyclopropane, or ether) in 26. The length of surgical procedure ranged from 20 minutes to 6 hours. Twenty-five patients manifested hypotensive episodes of varying length and degree during the operation or during the immediate postoperative period. The occurrence of the hypotensive state usually coincided with, or was followed by, a myocardial infarction in 29 patients. Two patients of this group were in surgical shock for several hours, 2 developed acute pulmonary edema, and 2 manifested congestive heart failure. Diagnosis of myocardial infarction was made in approximately one-third of the group on the day of operation, in one-third within the first 3 days, and in the remaining one-third between the 4th and the 6th day of the postoperative period. Eleven patients (31.4%) died within 10 days after the onset of the myocardial infarction. In all these patients death was directly related to this state. Autopsy performed on 6 of these patients confirmed clinical diagnosis. The clinical course in most of the patients who survived was rather mild; in 6 the electrocardiograms returned to normal within 10 to 16 days.

The treatment of patients with postoperative myocardial infarction is similar to that of myocardial infarction unrelated to surgical procedure. However, certain complicating factors are involved. In patients of the older age group, and in the presence of preexisting coronary artery or other thromboembolic disease, unless specific contraindication exists, prophylactic anticoagulants administered from the 3rd to the 10th postoperative day may be of help. The prevention of postoperative myocardial infarction is one of the important problems in surgery today. The measures already employed include optimum preparation of the patient from the standpoint of heart failure, arrhythmias, anemia, electrolyte imbalance, decrease of anxiety, and performance of the operation with a minimal degree of tissue damage, anoxia, and blood loss. Hypotension should be avoided where possible. When it occurs, early recognition should be made and immediate therapy with vasopressor agents and transfusions instituted, if necessary. The longer the duration of the hypotensive state, the greater is the likelihood of the development of myocardial infarction and the greater its extent. Routine electrocardiograms should be taken during the postoperative period, particularly in the group in which complications tend to occur. In older patients the prognosis in extensive infarction is poor. Early diagnosis and appropriate therapy may be of help in decreasing the mortality from this process.

Pulmonary Infiltration and Fibrosis of Unknown Origin: The Risk of Developing Active Pulmonary Tuberculosis. J. F. Chase, S. D. Rockoff and L. P. Hellman. A. M. A. Arch. Int. Med. 102:367-374 (Sept.) 1958 [Chicago].

It is difficult to determine the significance of roentgenographically unchanging pulmonary lesions in persons with inconclusive bacteriological and pathological findings The problem of the diagnosis of these cases is of special importance to the Armed Forces where intimate environmental situations exist. In an attempt to define the risk of development of active pulmonary tuberculosis in persons with predominantly noncalcified pulmonary lesions, proved by clinical study to be "stable" or "inactive," a study group of 268 Naval and Marine Corps personnel, who were hospitalized and returned to duty in 1951 with a diagnosis of pulmonary infiltration or fibrosis of unknown origin, were followed for 3 years. All patients who had had a diagnosis of active tuberculosis during or prior to 1951 were excluded. A control group consisting of 493 Naval and Marine Corps personnel, who were hospitalized and returned to duty in 1951 with a diagnosis of hemorrhoids, were also followed for 3 years. These subjects were chosen, because there is no known relationship between hemorrhoids and tuberculosis, and the over-all age distribution was similar to that of the study group. Tuberculosis has not occurred in any member of the control group, whereas active pulmonary tuberculosis developed in 16 of the subjects of the study group (5.9%), in several of whom the diagnosis was made within 8 months after the 1951 hospitalization. Examination of the records and roentgenograms revealed that in all 16 patients the active disease process occurred in the same area of the lung which had been clinically investigated at the patients' previous hospitalization.

The high incidence of active pulmonary tuberculosis in persons with pulmonary lesions diagnosed as mostly noncalcified "inactive" pulmonary infiltrations, or fibrosis of undetermined origin, illustrates the error of assuming that such lesions have no clinical significance. The problem of early diagnosis in these subjects can be solved only by frequent and thorough follow-up examinations over a prolonged period, and for this purpose the establishment of a standardized procedure of examination and a central registry of case reports appears to be advisable.

Regional Enteritis: I. Clinical Aspects and Diagnosis in 100 Patients. J. E. Daffner and C. H. Brown. Ann. Int. Med. 49:580-594 (Sept.) 1958 [Lancaster, Pa.]

The authors report on 53 male and 47 female patients, between the ages of 16 and 70 years, with regional enteritis who were seen in the department of gastroenterology of the Cleveland Clinic between 1946 and 1956. Fifty-five of the 100 patients were less than 31 years of age, the disease being predominantly one of young adults. It occurs in older patients, though, since 15 patients were over 50 years of age. The symptoms initially may be mild and may be present for a long time before the diagnosis is made; the average duration of symptoms in the 100 patients was 2.9 years. The chief symptoms were colic or abdominal pain in 88 patients, diarrhea in 81, loss of weight in 70, gastrointestinal bleeding in 34, draining sinus in 33, fever in 32, and anal fistula in 14. Many patients initially had only one symptom, and a few had all the symptoms listed. Physical examination revealed fistulas in 48 patients, an abdominal mass in 35, signs and symptoms of partial obstruction of the small intestine in 30, and abscesses in 15. The ileum was involved in 98 patients. Systemic complications were not so frequent as they are in ulcerative colitis, and they usually subsided with adequate treatment of the regional enteritis.

Roentgenologic findings on barium enema examination were diagnostic in 85 patients and falsely normal in 4; 11 patients did not undergo this examination. Roentgenologic examination of patients with regional enteritis should include a flat plate of the abdomen to detect possible obstruction, and barium enema studies should follow. Since the ileum is so frequently involved, findings on barium enema study may be diagnostic. Motility studies of the small intestine should then be done to determine the degree and extent of the disease. The diagnosis of regional enteritis could be made earlier in the course of the disease if there were a greater awareness of the signs and symptoms of the disease. A patient may have only one of the typical symptoms or findings, but that alone should indicate the possible presence of regional enteritis. The greater the number of typical symptoms or findings in a patient, the more likely is the diagnosis to be regional enteritis. If the clinical findings strongly suggest regional enteritis, the diagnosis should be made even when the roentgenologic findings are normal.

Regional Enteritis: II. Results of Medical and Surgical Treatment in 100 patients. C. H. Brown and J. E. Daffner. Ann. Int. Med. 49:595-606 (Sept.) 1958 [Lancaster, Pa.].

Of the 100 patients reported on in the preceding paper, 35 received only medical treatment and 65 were subjected to surgical treatment. Fourteen of the 100 patients were followed up for less than one year. The remaining 86 patients were followed for periods ranging from 1 to 12 years; the average follow-up period in these patients was 5.2 years. Twenty-three of the 35 medically treated patients showed a satisfactory response, 3 an unsatisfactory response, and 9 were followed for less than one year. The effects of specific drugs given to these patients were difficult to establish, but apparently oxytetracycline (Terramycin) was beneficial in 4 patients and streptomycin in 5. Steroid therapy was of help in 5 of 10 patients, and roentgenotherapy in 3 of 6 patients. These findings suggest that medical therapy can be of benefit in patients with regional enteritis who have no severe complications which require surgical treatment.

All the 65 patients who were operated on had complications of regional enteritis; 30 had intestinal obstruction, 25 had fistulas, 13 had abscesses, and 9 had severe anemia or hemorrhage. The indications for surgical treatment were these complications of the disease rather than the disease itself.

Sixty of the 65 patients were followed for more than one year; 28 of the 60 had resection and 32 had ileocolostomy with or without exclusion, ileostomy, or enteroenterostomy respectively. The results of operation were good in 32 patients, fair in 14, and poor in 12; 2 patients died, but these 2 deaths were not related to the enteritis. Of the 28 patients subjected to resection, 20 had good results, 3 had fair results, 4 had poor results, and 1 died. The postoperative recurrence rate was high: 63% for the entire group and 54% for the group of patients who underwent resection. Of the 38 patients with postoperative recurrence, 18 were treated medically and 20 underwent a second operation. Two of the 38 patients were lost to follow-up. Thirty-one of the remaining 36 patients responded satisfactorily to the further treatment. The results obtained in this series of 100 patients warrant an optimistic approach to the treatment of regional enteritis.

Viremia in Human Mumps Virus Infections. J. R. Overman. A. M. A. Arch. Int. Med. 102:354-356 (Sept.) 1958 [Chicago].

The various complications which may follow mumps parotitis, such as meningoencephalitis and orchitis, suggest that the virus is widely disseminated throughout the body, but viremia has previously been demonstrated by only one worker in a patient with this contagious disease. Mumps virus is easily recovered from the spinal fluid and has recently been demonstrated in the urine. The present paper reports 3 successful isolations of this virus from the serum of 2 of 15 patients with mumps virus infections. Serum antibodies to mumps virus had not yet appeared in the blood of these patients at the time the virus was isolated. The reason why mumps virus can so rarely be isolated from the serum of patients with mumps virus infections is still unknown.

Diazotization Rate of Bilirubin Content of Blood as a Diagnostic Aid in Biliary Colic. L. Schalm. Nederl. tijdschr. geneesk. 102:1537-1539 (Aug. 9) 1958 (In Dutch) [Amsterdam].

If gallstones are present in a patient who complains of epigastric pain, it is important to ascertain whether these calculi account for the symptoms, particularly if the patient shows no signs of jaundice. It is important to determine in such patients the bilirubin level of the blood, particularly the percentage of bilirubin diazotized in 10 minutes. The author calls attention to a method which he, together with Schulte, described in 1950 and in 1953. On the basis of illustrating case histories he shows that, if soon after the attack of epigastric pain there is a noticeable rise in the total bilirubin content of the blood with a considerable increase in the 10-minute diazotization rate, this positive reaction is strongly indicative of cholelithiasis as a cause of the symptoms. The case of a patient with a stone present in one of the hepatic ducts showed that determination of the alkaline phosphatase value may constitute a further refinement of the diagnosis.

Wilson's Disease, Especially with Regard to Biochemical Disturbances. E. Enger. Tidsskr. norske lægefor. 78:781-784 (Aug. 15) 1958 (In Norwegian) [Oslo].

In hepatolenticular degeneration (Wilson's disease), a rare hereditary disease due to disturbances in copper metabolism, copper is deposited in the tissues. The plasma content of copper and ceruloplasmin is reduced. The ceruloplasmin reduction is constant and considerable; the reduction in the copper content is variable and less marked, which leads to increase in the amount of copper not bound to the ceruloplasmin. The increase in the diffusible copper fraction predisposes to metal deposit in organs with greater affinity to copper than the serum albumin has. This affects particularly brain, liver, kidneys, and cornea. Another diagnostically significant biochemical deviation is the considerably increased copper excretion in the urine. Disturbances in the copper metabolism depend on genetic defects. Heredity is recessive. In about 75% of the cases, the clinical picture is dominated by damage to the brain; in most of these cases there is simultaneous hepatic damage. In about 20% of the cases, cirrhosis of the liver stamps the picture, but sooner or later signs of damage to the brain appear. In the remaining 5%, the so-called abdominal form of Wilson's disease, simultaneous involvement of the brain is not demonstrable.

Biochemical examination will disclose the pathological copper metabolism of Wilson's disease. Kayser-Fleischer rings in the cornea, seen only in this condition, are present in from 60 to 90% of the cases. The first symptoms, as a rule, appear between the ages of 15 and 25 years, but the debut may come in early childhood or later. Death usually occurs in from 2 to 4 years; acute cases of a few months' duration are not rare, and a chronic course has been reported. In 1951 increased excretion of copper in the urine on administration of dimercaprol (BAL) was reported. Penicillamine and Versene, recently introduced, cause a stronger copper excretion than BAL. Treatment with these medicaments has given clinical improvement even in cases with the fully developed picture. Lasting improvement can hardly be hoped for in advanced cases. Ceruloplasmin examinations, however, afford the possibility of revealing the disease in clinically well persons; here good results of treatment can be looked for.

The author reports the case of a man, aged 35 years, in whom Wilson's disease was diagnosed on signs of hepatocerebral damage, Kayser-Fleischer rings in the cornea, reduced uric acid level, increased elimination of amino acids and copper in the urine, and increased copper content in the tissues. Treatment with BAL was without avail. The patient died 7 months after the initial symptoms. The histological results confirmed the clinical diagnosis. The pattern here deviated from the usual in that the serum ceruloplasmin was normal. The author concludes that in advanced cases the biochemical disturbance can become so complicated that the usual reduction in the ceruloplasmin content of the serum is masked.

SURGERY

Treatment of Severe Head Injuries. I. N. Maciver, L. P. Lassman, C. W. Thomson and I. McLeod. Lancet 2:544-550 (Sept. 13) 1958 [London].

The development of decerebrate rigidity and hyperpyrexia, either separately or together, in patients who have sustained severe head injuries must be regarded as ominous. A retrospective survey showed that in cases of this type the mortality was 77%. The adoption in December, 1956, of a method of treatment designed to counteract respiratory insufficiency and to prevent or relieve cerebral edema brought about a statistically significant reduction of this mortality to 38.4%. The most important features of the treatment (which is described in detail by the authors) are (1) correct posture to prevent seepage into the lungs and tracheobronchial tubes; (2) isolation of the lungs from the disorganized pharynx by early tracheotomy; (3) further protection of the lungs by continued aseptic tracheobronchial toilet; (4) use of a lytic cocktail to coordinate the reticular mechanisms of the brain stem and to control rigidity, restlessness, and hyperthermia; (5) avoidance of oral feeding during unconsciousness; (6) maintenance of physiological tensions of oxygen and carbon dioxide in the blood; (7) maintenance of fluid and electrolyte balance and calorie intake; (8) use of antibiotics to combat infection; and (9) relief or prevention of secondary cerebral edema by the intravenous administration of triple plasma.

The clinical picture in the 26 patients treated by this method and in a control group of 56 patients meeting the same diagnostic criteria varied according to the degree of damage to or compression of the brain stem. The best prognosis attended the cases in which the patients showed hyperpyrexia with tonic fits superimposed on decerebrate rigidity. The poorest prognosis accompanied the cases marked by complete thermolability and absolute flaccidity save when disturbed by feeble tonic fits. Medullary failure was imminent in the thermolabile and flaccid group, the blood pressure falling and the respirations becoming shallow, irregular, and gasping. Nevertheless, 2 patients with this clinical picture survived.

All 16 of the surviving patients in the treated group are under constant observation and have been subjected to psychological testing at regular intervals. Two women have shown fairly pronounced mental changes for some time, and one man is somewhat euphoric and a little childish, but he is extremely good-tempered and works well. Relatively few of the others have any physical or neurological deficit; 9 have returned to their pre-accident occupations and are managing well; 2 have gone back to light work, and both should return to their normal employment within a reasonable time; and 4 others either are or will presently be fit for light work.

Further improvements may make it possible to lower the mortality in patients with severe head injuries to 20%, but only if it is realized that respiratory insufficiency exists from the time of the accident and that steps must be taken at once to counteract it, both during transportation to a hospital or head-injury center and on arrival at a casualty department.

The Successful Removal of a Tumor from the Right Atrium Under Hypothermia. M. Krčílková, I. Musil, J. Navrátil and O. Olejník. Thorax 13:173-176 (Sept.) 1958 [London].

The authors report on a 14-year-old girl who was admitted to the surgical department of the University Hospital in Brno, Czechoslovakia, because of severe dyspnea and elevated erythrocyte sedimentation rate. Gross systolic distention of the jugular veins was noticed. There was a slight prominence of the chest in the precordial region and marked systolic pulsation of the right ventricle. The liver was enlarged. The heart sounds were indistinct, and a systolic murmur was heard in the 5th intercostal space, loudest near the right sternal border. The electrocardiographic tracing showed right bundle-branch block and right ventricular overload. A posteroanterior chest roentgenogram revealed enlargement of the right ventricle with expansile systolic pulsation of the right atrium. Both venae cavae were enlarged and showed intense distention during systole. Fluoroscopy revealed a dense, well-circumscribed, ball-shaped, and plum-sized mass within the shadow of the right atrium after the systolic and diastolic movement of the right heart in a quick, sometimes irregular, swinging curve. An angiocardiogram was made, which showed a defect in the contrast medium filling the right atrium and corresponding to the ball-like mass.

The patient was operated on with the aid of hypothermia at a lowest temperature of 80.6 F (27 C). A tumor mass measuring 4 by 5 by 5.5 cm.

and hanging on a stalk, which originated from the inferior part of the right atrial septum close to the posterior cusp of the tricuspid valve, was removed from the right atrium by division of its stalk. The postoperative period was uneventful, and the patient was discharged from the hospital 4 months after the operation. Microscopic examination of the surgical specimen revealed a tumor with myxomatous and fibrotic changes and with frequent calcification.

Primary tumors of the heart are rare, and in most of the cases collected from the literature the diagnosis was made at autopsy. It is to be expected that in the future cardiac tumors will be diagnosed more frequently during the patient's life and before operation, thanks to diagnostic improvements in cardiology and roentgenography.

The Follow-Up Study of 250 Patients Subjected to Surgical Treatment of Patent Ductus Arteriosus. N. Helsingen Jr., O. Husom and L. Efskind. Thorax 13:210-212 (Sept.) 1958 [London].

The authors report on 250 patients, between the ages of 14 months and 40 years, with patent ductus arteriosus who were operated on in the surgical department of the Rikshospitalet (surgical clinic of the University) in Oslo between 1944 and 1956. Except for the first 2 patients operated on, all had the usual dorsolateral transthoracic incision with wide opening of the thorax, and, as a rule, simple ligation of the ductus arteriosus was performed with 2 or 3 thick silk ligatures applied as far apart as possible. In 5 patients the duct was cut between clamps and sutured, and in 4 others sutures had to be placed on the aortic and pulmonary ends of the duct but without division. Three patients died, representing a mortality rate of 1.2%. Of the 3 deaths, one was attributable to accidental bleeding in the course of the operation; the second occurred during reoperation for a complicating aneurysm; and the third was caused by a tension pneumothorax occurring after a simple thoracentesis.

The patients were followed up for periods varying from 6 months to 13 years. All the patients were traced. The results of the surgical treatment were extremely satisfactory. The crucial point in the follow-up examination is the detection of patients with possible recanalization of the ductus arteriosus. In only 4 patients, 2 children, aged 8 and 12 years, and 2 adults, aged 29 and 23 years, could a continuous murmur of the "patent duct type" be heard at the follow-up examination, indicating recanalization. All 4 patients had had simple ligation of the ductus arteriosus. Three had wide ducts, and one probably had a subacute bacterial endarteritis postoperatively. The incidence of recurrence thus was 1.6%. This compared favorably with the reports by other workers of more than 10% recanalization after ligation of the ductus arteriosus. Under these conditions simple ligation is considered a safe procedure with a small chance of recurrence, except in patients with giant ducts and in elderly patients.

Results of Open Heart Surgery with Elective Cardiac Arrest by Potassium Citrate in Patients with Congenital and Acquired Heart Disease. F. M. Sones Jr. Dis. Chest 34:299-316 (Sept.) 1958 [Chicago].

Elective cardiac arrest, accomplished by perfusion of potassium citrate solution into the coronary circulation, made possible excellent surgical exposure of intracardiac structures during open cardiotomy in 80 patients with a variety of congenital and acquired lesions. The cardioplegic effect of potassium was reversed by perfusing the coronary arteries with oxygenated blood. In no instance was death or surgical failure attributable to the use of cardiac arrest. Forty-five patients survived. The postoperative status of surviving patients was evaluated on the basis of clinical findings and, when possible, by heart catheterization and cinecardioangiography 6 to 14 months after the operation. Anatomic correction with restoration of normal function may be anticipated in patients with atrial or ventricular septal defects, provided that complete absence of the septum is not encountered.

Severe pulmonary hypertension is not a contraindication to closure of septal defects if there is a large left-to-right shunt with increased pulmonary flow. In patients with the tetralogy of Fallot, inadequate closure of the ventricular septal defect has been found in most instances when a prosthesis has not been incorporated into the defect. These patients have shown clear-cut evidence of functional improvement, with increased pulmonary blood flow and relief of arterial hypoxemia, but anatomic correction and restoration of normal cardiovascular dynamics have usually not been obtained. Experience with this small group of patients emphasizes the need for further refinements in diagnosis, surgical technique, artificial perfusion, and postoperative management before the ultimate potential of open heart surgery may be realized.

Results of Treatment of Cystic Disease of the Breast: Five- to Eighteen-Year Survey. J. W. Hendrick. Surgery 44:457-482 (Sept.) 1958 [St. Louis].

This report is concerned with the clinical histories, operative findings, pathological reports, treatment administered, and follow-up examinations on 90% of a series of 484 private women patients treated for cystic disease of the breast between 1933 and 1951. The study was undertaken to determine the results of conservative therapy and to present clues to the etiology of cystic disease, particularly hormone influences, and the relation of this disease and breast cancer. Research has demonstrated that estrogenic stimulation over a period of time in ovariectomized mice will produce proliferation and metaplasia of the mammary duct epithelium, with dilatation of the ducts and acini and the formation of microcysts. This histological picture in mice is comparable to cystic disease in the human. The extensive use of estrogens in all forms for so-called menopausal symptoms in patients with nervous phenomena certainly should increase the incidence of cystic disease and carcinoma of the breast if the theory could be proved that estrogenic stimulation is related to malignancy of the breast. Since 1940, at least 60% of the patients in whom the author made a diagnosis of cystic disease or carcinoma of the breast had histories of having had estrogenic therapy in varying amounts over a period of months to several years. A number of these patients who were past the menopause stated that their breasts had been free of symptoms until the administration of estrogen therapy, after which their breasts became tender, tense, painful, firm, and nodular.

A follow-up of this series of 484 patients with cystic disease for a period of 5 to 18 years disclosed that carcinoma of the breast developed in only 4. Of 452 patients with primary carcinoma of the breast who were treated during the same period, 4 had previously undergone surgery elsewhere for benign lesions of the breast. Since some authors believe cystic disease of the breast to be a precancerous lesion and recommend mastectomy for its treatment, the question arises: What advice is the physician to give patients who consult him with painful, nodular breasts? It is the author's practice to assure the patient that there is no more likelihood of carcinoma developing in her breast than in that of any patient of comparable age without cystic disease and that mastectomy is not necessary except in rare cases. Since 1933 he has used aspiration therapy for discrete cysts of the breast, provided that the patient agrees to return at regular intervals for further evaluation. Only 7 of 167 patients with discrete lumps treated by aspiration had a residual mass after dry aspiration. Surgical excision of the residual tumors proved that they were benign in all 7. Patients with discrete cysts are advised that, if aspiration produces bloody fluid, if the lump does not completely disappear after aspiration, if fluid is not obtained, or in the event that the lump returns after a second aspiration, the involved area of breast will be excised for histological examination. Regular follow-up examinations of patients in whom aspiration was performed demonstrated that carcinoma was not overlooked in any instance.

Of 314 patients who had either a discrete cyst or an area of cystic disease localized to one segment of the breast, 311 underwent surgical excision of the involved area, whereas the other 3 patients required simple mastectomy due to severe mastodynia and the fact that the involved breasts were riddled with small cysts. In 67 patients treated by aspiration or surgical excision of a discrete cyst or segment of breast affected with cystic disease, a second cyst developed in the same or opposite breast after a period of several months to 16 years. The new cysts were successfully treated by aspiration therapy.

Statistics of Gallstones: Indications for Cholecystectomy. N. Enderlin. Schweiz. med. Wchnschr. 88:855-858 (Aug. 30) 1958 (In German) [Basel, Switzerland].

A total of 6,400 autopsy reports of the age groups over 10 years, which covered the period between 1950 and 1954, were reviewed at the Pathological Institute of the University of Zurich. The 6,400 patients included 1,000 who either had gallstones (898) or had undergone cholecystectomy (102). Thus, only about 10% of gallstone patients had been subjected to cholecystectomy. About 1 woman in 5 and 1 man in 10 had gallstones. The number of patients with gallstones rapidly increased after the age of 30, and it reached a maximum in the 7th and 8th decades. Generalized obesity existed in one-third of the patients with gallstones, and one-fourth had hypertension. Eight per cent had diabetes, which represents an increased incidence, since the average diabetes mellitus morbidity in the total population ranges from 0.25 to 0.4%.

Complications of cholelithiasis existed in 402 of the 1,000 patients, while the remaining 60% were free from pathologically demonstrable gallstone complications. Expressed in percentage rates, 20.4% had chronic cholecystitis; 6%, contracted gallbladder; 5.3%, cholangitis; 5.1%, biliary cirrhosis of the liver; 4.4%, pancreatitis; 3%, perforation of the gallbladder; 2.2%, liver abscess; 2%, empyema of the gallbladder; 1.7%, ectasia of the gallbladder; 1.5%, acute cholecystitis; 1.5%, hydrops of the gallbladder; and 1.3%, strawberry gallbladder. The complications of cholelithiasis were the only cause of death in 8.7% of the patients, and in an additional 7.8% they were a contributing cause. In the remaining 83.5% of the patients no causal connection existed between the gallstone disease and death.

The author feels that his statistical analysis suggests that patients with complications involving inflammation or an obstruction to bile drainage should be subjected to cholecystectomy. Surgeons generally suggest that the operation be carried out even before complications develop, inasmuch as the surgical mortality is only 0.6% in patients who are as yet free from complications, whereas after their development and at the more advanced ages it may reach 20%. The author feels that balanced judgment with a consideration of personal and individual factors is to be preferred to a purely statistical evaluation in deciding on a cholecystectomy. He believes that the operation is definitely indicated when the presence of gallstones is complicated by acute or chronic inflammation, by pancreatitis, and by processes that obstruct bile drainage. Relative indications for cholecystectomy are recurrent gallstone colics without jaundice or fever, epigastric discomfort, nausea, multiple small stones, and stones in young persons, particularly young women likely to become pregnant. In these instances the physician may recommend cholecystectomy but should leave the final decision to the patient. In patients with silent gallstones or with only minor complaints and a single attack of stone colic, an expectant attitude is justified.

Acute Pneumocholecystitis. R. Consoni, P. Tavares and H. Prisco. Rev. Assoc. med. brasil. 4:117-120 (June) 1958 (In Portuguese) [São Paulo, Brazil].

Acute pneumocholecystitis is due to the presence of gas-producing bacteria of the Clostridium genus in the lumen of the gallbladder. Pathogenicity of the bacteria greatly increases from contact with concentrated bile immediately after obstruction of the cystic duct by calculi, regional enlarged lymph nodes, adhesions, or the presence of abnormal regional blood vessels. The symptoms are those of acute cholecystitis, but they are even more acute. A roentgenologic diagnosis of pneumocholecystitis can be made within 24 or 48 hours after the appearance of the acute symptoms from the typical image of the gallbladder showing gas retention.

The authors review 22 cases from the literature and add 2 cases of patients whom they have observed. The disease was more frequent in patients between the ages of 50 and 60 years. There were 19 women and 5 men. Six patients had diabetes. A cholecystectomy was performed on 16 patients. In most of these the gallbladder was found to be necrotic or gangrenous. Often it was perforated, with diffusion of gas into the perivesicular tissues, or else there was a diffuse peritonitis from anaerobic bacteria. Twelve of the 16 patients who had a cholecystectomy recovered; 4 died of postoperative complications.

The authors advise systematic simple roentgenray examination of the upper quadrant of the abdomen in patients suspected of acute cholecystitis, for a roentgenologic diagnosis of acute pneumocholecystitis. Cholecystectomy is the treatment of choice. Conservative treatment should be reserved only for patients who seem to be poor operative risks. Even for these patients, the surgeon should be prepared for cholecystectomy if the clinical symptoms progress and daily roentgen-ray examination of the gallbladder shows increased size in gas contents or diffusion of gas into perivesicular tissues.

Surgical Management of Complicated Diverticulitis. B. P. Colcock. New England J. Med. 259:570-573 (Sept. 18) 1958 [Boston].

The author reports on 74 men and 57 women, between the ages of 30 and 77 years, with diverticulitis who were operated on at the Lahey Clinic in Boston between 1947 and 1958. Seventy-four (56.6%) of the 131 patients had had symptoms of the disease for one year or longer before the surgical intervention. Of the 131 patients, 69 (52.6%) had a one-stage resection with a primary anastomosis, 17 had a two-stage resection, 3 had a Mikulicz resection, 27 had a three-stage resection, 8 had resection combined with closure of colostomy, and 7 had other operative procedures. The length of hospital stay for patients having a one-stage resection ranged from 9 to 24 days, with an average period of 15 days. In patients having a three-stage resection, the hospital stay ranged from 37 to 84 days, with an average of 60 days. Two patients who underwent a two-stage resection died, representing a mortality rate of 1.5%. No deaths occurred in the other groups of patients.

Forty patients (30.5%) had previously undergone one or more surgical procedures that did not relieve symptoms or that led to further complications. Thus, inadequate surgery is one factor responsible for many complications associated with the surgical treatment of diverticulitis. In only 2 patients did an attempt at definitive surgical treatment fail when the accepted way of treating a complication of diverticulitis was employed—that is, colostomy, followed by resection and closure of the stoma. In the other 38 patients failure was attributed to the use of unsatisfactory surgical procedures that are known to be associated with a high incidence of poor results. One patient had a total of 8 operative procedures before cure was obtained. Patients with relatively uncomplicated diverticulitis may be subjected to definitive surgery, with a single operative procedure, a short period in the hospital, and a low mortality. Resection of the diseased intestine stops the recurrent attacks; perforation, obstruction, and fistula formation are avoided; and the danger of allowing unsuspected carcinoma to go untreated is eliminated.

Observations on Intraperitoneal Adhesions: An Experimental Study. B. B. Jackson. Surgery 44:507-514 (Sept.) 1958 [St. Louis].

The observations described represent a pathophysiological study of the natural evolution of intestinal adhesions as visualized through a transparent plastic window in the abdominal wall of the dog. Eight dogs, weighing at least 20 kg. (44 lb.), were used. A 6-by-8-cm. elliptical Plexiglas window, with a 90 to 92% light transmission and a haze of 5 to 10%, was utilized, being contour-shaped for each dog. A screw tap was placed at one end of the window, so that measurements could be taken or fluid aspirated without removing the window. A stainless steel foundation mesh was sutured around the window with wire. After the rectus muscles had been excised, the window was sutured between the anterior and posterior fascial sheaths. Sterilization of the window was accomplished with 1:1,000 Zephiran solution for 24 hours. The natural history of the postlaparotomy adhesion appears to be trauma, capillary dilatation, stasis, increased capillary permeability, fluid loss, fibrinous exudate, decrease in pulsations in the vasa rectae, relative anoxemia, diminution in peristalsis, release of proteolytic enzymes from white blood cells, increase in intraperitoneal fluid, resorption of fibrin, recanalization of capillaries, return of arterial pulsations, and resumption of peristalsis.

The extent of the adhesion is directly proportional to the injury, whether it be chemical, bacterial, thermal, or mechanical. Peritonitis productive of heavy fibrinous exudate frequently results in broad, vascular, permanent, fibrous adhesions. Blood, free or clotted, in the peritoneal cavity does not incite the formation of adhesions but provides an excellent medium for bacterial contamination which may subsequently be responsible for numerous dense adhesions. Heparin inhibits adhesions only before the stage of fibrinous deposition, whereas streptokinase which activates fibrinolysin destroys the early fibrinous film. Those agents tend to inhibit localization of infection when they are used intraperitoneally. Induced intestinal hypermotility to prevent adhesions seems to perpetuate a normal tissue response to injury. The hyperactivity tends to increase the ischemia of the intestinal wall, which prolongs the phase of capillary transudation. The Plexiglas window provokes adhesion development and reperitonealization in 20 to 30 days. The evolution of the uncomplicated intraperitoneal fibrinous adhesion lasts approximately 48 to 96 hours. Efforts to shorten this period appear to complicate a natural healing phenomenon with longer period of adynamic ileus and/or the development of permanent fibrous adhesions.

Control of Surgical Infections at the Minneapolis General Hospital: A Two Year Study. C. R. Hitchcock, H. Harder, M. Panuska and others. Surgery 44:492-506 (Sept.) 1958 [St. Louis].

During the early summer of 1956 the surgical staff at the Minneapolis General Hospital became alarmed over the mounting number of "clean" surgical wounds infected with staphylococci, and a study was organized. This paper deals with investigations extending over a period of 25 months. The committee on infections included the superintendent, the chief of surgery, a representative from the department of medicine, the chief operating-room nurse and her assistant, the research bacteriology technician, the pathologist, the director of housekeeping, and the chief engineer. The investigators had access to records of infections on the surgical services for an 8-month period prior to the formation of this committee. The hospital investigated serves as an emergency center and as an outpatient and inpatient facility. During the course of a year it treats approximately 45,000 persons on a total of about 110,000 hospital visits or admissions. The preponderance of older and debilitated patients on the inpatient services greatly heightens the risk of serious infections. In one year (1955) 648 patients were seen in the emergency room with infections requiring either outpatient treatment or admission to the hospital.

The authors believe that all changes instituted during the past 18 months have contributed in some measure toward better control of wound infections. The following remedial measures appeared to be of significance: 1. Monthly meetings of the committee reviewed the reports on all patients with wound infections, and the tabulation of these problems on the surgical services permitted statistical analysis of the results. 2. In the absence of adequate facilities for complete isolation of all patients infected with staphylococci, the prevention of cross contamination on the open wards was aided by stopping the interchange of blankets and fomites among patients and by improving dressing techniques. 3. The preoperative skin preparation was changed from soap or hexachlorophene solution and aqueous Zephiran to ether and alcohol and tincture of Zephiran; during the latter phases of this study Dreft replaced the initial ether rinse, and the results appear to be satisfactory. 4. Improvements in housekeeping procedures both in the operating rooms and on the surgical wards were of value.

During the early phases of this study an improvement of 620% was made in the staphylococcic infection rate of clean wounds, and the improvement has continued to date. At present the over-all infection rate is less than 2%. Bacteriological sensitivity studies have yielded a common pattern of antibiotic resistance for a high percentage of the staphylococci involved. The organisms are undoubtedly a strain of the Staphylococcus genus indigenous to the hospital, which contaminate the skin, nasal passages, and gastrointestinal tract of patients during the course of their hospitalization. The control of antibiotic-resistant staphylococci looms as one of the most pressing problems with regard to safe performance of surgical procedures. This problem can be controlled in a large city hospital engaged in teaching medical students, interns, and residents if suitable techniques of asepsis and antisepsis are instituted. Constant vigilance on the part of the entire hospital staff is mandatory if improvements are to continue.

NEUROLOGY & PSYCHIATRY

Abnormalities in Central Regulation of Respiration in Acute and Convalescent Poliomyelitis. F. Plum and A. G. Swanson. A. M. A. Arch. Neurol & Psychiat. 80:267-285 (Sept.) 1958 [Chicago].

The authors performed clinical, physiological, and pathological studies on the nature of central respiratory failure in patients with anterior poliomyelitis who were admitted in the acute stage of the disease to the King County Hospital in Seattle and the Providence Hospital in Anchorage, Alaska, or were convalescing from poliomyelitis at the Northwest Respiratory and Rehabilitation Center. Central respiratory disturbances were noted in 7 female and 13 male patients, between the ages of 5 and 36 years, during the acute illness, and in 2 patients during late convalescence. The pattern of development and progression of centrogenic respiratory decompensation in acute poliomyelitis was similar in most of the 20 patients and could be divided into 3 stages. In stage 1 respiratory irregularity appeared only during sleep and was unnoticed by the patient. Stage 2 was marked by more serious physiological defects in respiration, and dysrhythmic breathing persisted during waking hours. Effort or concentration was required to maintain compensation for oxygen and carbon dioxide. Impaired chemosensitivity to carbon dioxide was indicated by depression of ventilation while the patient was breathing oxygen. Stage 3 was that of respiratory decompensation; hypoxia or hypercapnia rapidly appeared unless artificial respiration was started. Of the 20 patients, the centrogenic respiratory abnormalities did not progress further during the illness than stage 1 in 7 patients; they progressed to stage 2 in 5 patients and to stage 3 in the remaining 8.

No specific treatment was required for the breathing defect in stage 1. Artificial respiration by tank respirator was required sooner or later to treat all 13 patients in stage 2 or stage 3. It was learned that depressant drugs accelerate markedly the deterioration of central respiratory control in acute poliomyelitis; their administration must, therefore, be avoided in acutely ill patients, and oxygen therapy could be used safely only in conjunction with artificial respiration. When general anesthesia was employed for tracheotomy, it proved necessary to follow it with artificial respiration. Three of the 20 patients died of fulminating disease of the brain stem and central respiratory failure. Autopsy was performed on one of the 3 patients, and tissue blocks from the brain of another patient with central respiratory failure were obtained for examination. In both patients marked inflammatory changes and neuronal alterations were observed in the medullary reticular formation, and small necrotic foci in the ventrolateral reticular formation.

Irregular respiration during sleep persisted in 2 patients for many months after the acute poliomyelitis. These same patients also showed carbon dioxide retention without dyspnea, an impaired ventilatory response to increased tensions of inspired carbon dioxide, and reduction in ventilation while breathing 100% oxygen. These physiological abnormalities were attributed to permanent abnormalities in the functioning of the medullary respiratory center. Seven of 9 patients convalescing from spinal paralysis and having values of maximal breathing capacity and vital capacity of less than 50% of the predicted normal also showed subnormal responsiveness to carbon dioxide as a respiratory stimulus. It appears that in poliomyelitis, as in pulmonary emphysema, peripheral mechanisms restricting chest motion may contribute to an impaired ventilatory response to carbon dioxide. The clinical and physiological findings in the patients with central respiratory failure associated with poliomyelitis support the concept that an intrinsic and sensitive function of the medullary respiratory center is to establish the rhythmicity of breathing.

Implications of a Five-Year Study of 700 Basal Ganglia Operations. I. S. Cooper and G. J. Bravo. Neurology 8:701-707 (Sept.) 1958 [Minneapolis].

The authors present a summary of an intensive study of the effects of 700 globus pallidus and thalamic lesions in persons afflicted with Parkinsonism and diverse involuntary movement disorders. Follow-up of 55 patients who were subjected to elective anterior choroidal artery occlusion has demonstrated that this operation provided the most complete and lasting relief of far-advanced incapacitating rigidity, tremor, and deformity heretofore reported anywhere in the literature. Many of the patients have become ambulatory and independent in their daily life. The following conclusions can be documented as a result of follow-up studies of these 55 cases: 1. The effectiveness of anterior choroidal artery occlusion is due to infarction of more than a single anatomic structure. 2. Total relief of tremor, rigidity, incapacitation, and deformity is possible without inflicting any neurological deficit upon the patient. 3. Objective evidence of 5-year cure of the Parkinsonism symptoms of tremor, rigidity, and deformity has been achieved by anterior choroidal artery occlusion. 4. The dystonic deformities seen in some Parkinsonian patients are not actually fixed deformities but represent forced postures which are reversible even after many years' standing. 5. The so-called anterior choroidal artery syndrome is not invariable, and in many instances this vessel may be completely occluded without producing neurological deficit. 6. The ability of this procedure to relieve tremor and rigidity without inflicting neurological deficit warrants further consideration of other techniques which might be more universally applicable to a broader segment of the Parkinsonian population.

The techniques of chemopallidectomy and chemothalamectomy combine roentgen-anatomic methods of lesion placement deep in the brain. The production of a large lesion in the globus pallidus proved to be a relatively simple procedure with a small mortality and morbidity rate, favorable results having been obtained in 70% of the cases. Although rigidity could be relieved in 80% of such cases, tremor was alleviated in only 60%; however, when tremor was the presenting symptom, a lesion placed in the region of the ventrolateral nucleus of the thalamus provided complete relief of tremor in 90% of the patients. Tremor, rigidity, incapacitation, and deformity of Parkinsonism can be relieved by properly placed lesions in the globus pallidus or the thalamus or both without inflicting any motor, sensory, or intellectual deficit upon the patient. The extent to which such lesions can be inflicted on both sides of the brain is deserving of further elucidation.

A New Adjunct to the Treatment of Alcoholism: The Hallucinogenic Drugs. C. M. Smith. Quart. J. Stud. Alcohol 19:406-417 (Sept.) 1958 [New Haven, Conn.].

This paper describes a preliminary attempt to evaluate 2 hallucinogens in the treatment of a group of 24 particularly refractory alcoholics. LSD-25 (*d*-lysergic acid diethylamide) and mescaline were used as adjuncts to treatment, consisting of superficial psychotherapy supplemented by occupational and recreational therapy. The hallucinogens often produce, in addition to perceptual disturbances, a particularly vivid and intense awareness of personality problems. It was felt that these experiences might be utilized as part of a therapeutic program. The experience of "hitting bottom" has been much discussed in the Alcoholics Anonymous (A. A.) literature. It is at this time that the alcoholic addict is often susceptible to therapy. It was thought that these drugs might make the patient "hit bottom" artificially and thereby render him more amenable to psychotherapy. An attempt was made to enter into a psychotherapeutic relationship with the patient and to delineate the main problems. This phase lasted 2 to 4 weeks. The building up of adequate rapport was of critical importance, and on it largely depended the success or failure of the next phase. The patients were next given a single dose of LSD-25 or mescaline orally while in hospital. It was noted that alcoholics tend to be resistant to these drugs, and doses of 200 to 400 mcg. of LSD or 0.5 Gm. of mescaline were used. In addition to discussing with the patient problems leading to and arising out of his drinking, suggestions were made to the effect that he discontinue the use of alcohol, but no attempt was made to arouse fear. Discussions were resumed during the next few days, and the patient was discharged.

In some cases, follow-up psychotherapy was possible; in most, however, further contact was made through A. A. The follow-up period ranged from 2 months to 3 years. The average duration of the follow-up was one year. Many patients noticed a transient nausea half-hour to 2 hours after taking either drug. Three patients vomited, though not severely. The psychological effects varied greatly and persisted for an average of 8 or 9 hours. All patients felt well by the following day. Some of the patients showed mild abnormalities of the liver function tests. Yet these patients did not show an enhanced reaction to the drugs. Improvement was obtained in 12 of the 24 patients. In view of the refractory nature of the group, the results appear sufficiently encouraging to merit more extensive and controlled trials.

Toxic Effects of Disulfiram Therapy with Two Case Reports. N. H. Rathod. Quart. J. Stud. Alcohol 19: 418-427 (Sept.) 1958 [New Haven, Conn.].

The mode of action of disulfiram, which has been used in the treatment of alcoholism since 1948, is not completely understood, but it is postulated that many of the effects produced by the combination of disulfiram and alcohol in the body result from disulfiram interfering with the metabolism of acetaldehyde. Its administration is thought to be contraindicated in hypertension, pregnancy, diabetes mellitus, and diseases of the liver, kidneys, and thyroid. Side-effects associated with disulfiram therapy include fatigue, sleepiness, headache, dizziness, reduced vitality, and reduced potency. Toxic phenomena attributed to the drug have included initial tiredness, with subsequent disorientation, disinterestedness, loss of memory for recent events, anxiety, depression, paranoid equivalents, and restlessness. It is not clear, however, whether the toxic reactions are due to disulfiram entirely.

The histories of 2 patients are presented, in each of whom toxic symptoms developed on 2 separate occasions while they were receiving disulfiram, and on each occasion these symptoms subsided when a placebo was substituted. At no time did the patients know what type of medication they were receiving. Similar toxic symptoms developed in both patients in spite of marked differences in physical state, personality, and duration of treatment. Neither of the patients had a family history of psychiatric illness, and even though both had suffered from adverse effects of alcohol, the symptoms noted under disulfiram therapy showed little resemblance to those due to alcohol in the past. The second patient showed marked abnormality of the electroencephalogram while suffering from the effects of disulfiram, but this more or less cleared on clinical recovery.

The toxic phenomena noted in these patients were similar to those mentioned above. They seemed exogenous in origin and of a toxic-confusional nature with depressive features. Depersonalization phenomena, paranoid ideas, and perseveration were noted in individual episodes. The onset of the symptoms was insidious with a tendency to sudden exacerbation. The last symptoms to clear up were the memory disturbances and disorientation. A significant point is that both patients had had delirium tremens in the past. This raises the question of whether persons who had not suffered from any functional and structural disorder of the brain would develop such symptoms when given disulfiram. This question cannot be answered.

GYNECOLOGY & OBSTETRICS

Some Observations on the Incidence of Pre-Eclampsia. I. MacGillivray. J. Obst. & Gynaec. Brit. Emp. 65:536-539 (Aug.) 1958 [London].

Preeclampsia is difficult to define. The patient's prepregnancy blood pressure should be known, or at least the pressure in the first trimester, that is, before preeclampsia has begun to affect it. This report is concerned with a study of the incidence of preeclampsia in booked primigravidas in the Aberdeen Maternity Hospital during the years from 1948 to 1955. Since more than 90% of all Aberdeen primigravidas are confined in hospital, the group under review is fairly representative of all such patients in the city. A retrospective study of case records was used to study the influence of certain factors on the incidence of preeclampsia, with the following conclusions: 1. The condition is typically a disease of the primigravida, severe preeclampsia being about 15 times greater in a first than in a second pregnancy. 2. When the first pregnancy ends in abortion, the incidence of severe preeclampsia in the next pregnancy is only 2% compared with 6% in a primigravida. 3. Twin pregnancy increases the incidence in a primigravida by 5 times, and it is still high in a second pregnancy. 4. Threatened abortion does not predispose to preeclampsia. 5. Stature and social class do not influence the incidence. 6. The incidence of mild preeclampsia seems to be increased in primigravidas over 30 years of age.

Treatment of Eclampsia: First Use of a Steroid Anesthetic, the 21-Hydroxypregnanedione Sodium Succinate: A Preliminary Note. G. Martini, A. Pesce and G. Rugiero. Minerva ginec. 10:511-514 (July 15) 1958 (In Italian) [Turin, Italy].

Viadril (21-hydroxypregnanedione sodium succinate) produced complete remission of convulsions in 5 patients with eclampsia, 2 of whom had previously been unsuccessfully treated with other anticonvulsive drugs. A total dosage of from 4,000 to 5,000 mg. of Viadril was divided into several doses administered intravenously every 2 or 3 hours. The initial dose of 500 mg., dissolved in 20 cc. of distilled water, was followed by doses of from 500 to 1,000 mg. each. A hypnoanalgesic state, which developed 10 minutes after the first administration of the drug and lasted 30 to 60 minutes, was followed by drowsiness of an hour or two duration. The patients reacted to stimulus, though, and moved in bed, and some of them could talk. This state of semiconsciousness was an intermediate one between physiological sleep and loss of sensation in anesthesia. Induction of this state reduced the cortical excitation; it produced a certain degree of hypnosis, amnesia, analgesia, and, to a smaller extent, hypotension. No toxic effects were observed either in the mothers or in the fetuses, and there was no evidence of cerebral damage caused by anoxia. Renal disorders associated with eclampsia changed insignificantly. Blood pressure decreased by 20 to 40 mm. Hg for a few hours; it returned to the initial level, however, unless the administration of the drug was repeated. The state of confusion disappeared when the patients were kept for a sufficient length of time in semihypnosis. It seems that Viadril reduced the state of high cortical and neurovegetative excitability as the cause of tonicoclonic convulsions. Therapy with detoxicating agents was instituted after remission of eclampsia.

Cesarean Section for Cephalopelvic Disproportion After Previous Vaginal Deliveries. J. B. Davila and G. Rivera-Ayala. Bol. Asoc. méd. Puerto Rico 50: 243-248 (July) 1958 (In English) [Santurce].

Twenty-one thousand one hundred forty pregnant women were delivered in the department of obstetrics of the San Juan City Hospital between 1952 and 1957. Two hundred twenty-two women were delivered by cesarean section because of the presence of cephalopelvic disproportion. This group included 199 primiparas and 23 multiparas who had previously had 3 or more vaginal deliveries. Of the babies of the 23 multiparas who were delivered by cesarean section, 19 were larger and weighed more than the largest baby previously delivered vaginally by the same mother; four babies were smaller and weighed less. The total length of labor in the preceding vaginal deliveries ranged from 2 to 27 hours, whereas the length of labor prior to cesarean section was between 1½ and 36 hours. Of the 23 babies of mothers delivered vaginally, 18 were in good condition at birth, 2 were born in poor condition and died on the second day, and 3 were stillborn. Of the 23 babies of the same mothers delivered by cesarean section, 22 were in good condition at birth, and 1 was stillborn. The possibility of vaginal delivery does not depend only on the relationship of the head of the baby and the pelvis of the mother. In a woman who has delivered vaginally, subsequent pregnancies will not always end with a vaginal delivery.

In one with a borderline pelvis, if the difference in weight of the 2 babies is only a few ounces, the previous heavier baby may have been born vaginally in very poor condition, or dead, after a difficult labor. Also, presentation and position of the babies may be different, that is, occiput posterior or breech, and weight of the previous baby may have been incorrect.

In determining the method of delivery (vaginal or cesarean section) to be used in a given case, in either a primipara or a multipara, the authors suggest the following scheme: (1) prenatal evaluation of the pelvis by vaginal examination and (2) evaluation of the pelvis if the patient has been in labor for 12 hours and has not delivered. For a multipara only they suggest: (1) evaluation of the pelvis as a routine when the woman is admitted to the labor room with a floating vertex or a malpresentation; (2) evaluation of the pelvis when the patient develops secondary inertia during labor; and (3) evaluation of the pelvis when she has been in labor for 15 or 30 minutes after full dilatation and has not delivered. X-ray pelvimetry is of value in evaluating the pelvis of a multipara with a floating vertex or a malpresentation.

Examinations of the Menstrual Blood for Tubercle Bacilli in a Sanatorium for Pulmonary Tuberculosis. G. Pickroth. Tuberkulosearzt 12:569-572 (Sept.) 1958 (In German) [Stuttgart, Germany].

The diagnosis of tuberculosis of the internal female sex organs by examination of the menstrual blood has been improved considerably with the use of Niedner's hematophor. This is an instrument made of fireproof glass which is easily inserted into the vagina. The blood is collected directly from the opening of the cervix and will not be mixed with any discharge of the vagina. Of 101 women with pulmonary tuberculosis who were admitted to a sanatorium in Jena, Germany, only 5 had known tuberculosis of the internal sex organs. Examination for the detection of tubercle bacilli in the internal sex organs was performed with the use of the hematophor in 56 of the 101 patients (including the 5 mentioned above), while in the remaining 45 patients this type of examination was not performed for various reasons. With the exclusion of the 5 patients with known tuberculosis, the presence of Mycobacterium tuberculosis in the menstrual blood was detected by culture in 10 of the remaining 51 patients. The gynecologic findings were negative in 7 patients and insignificant in 3. Patients were given chemotherapy only after withdrawal of the menstrual blood, in order not to interfere with the detection of tuberculosis, and in this way the rate of positive findings in the menstrual blood increased from 16 to 20%. Since the tubercle bacilli in the internal sex organs may possibly spread to other organs in the patient's body, routine examination of the menstrual blood with the hematophor should be performed in sanatoriums for patients with pulmonary tuberculosis as an important aid in early diagnosis of tuberculosis of the internal sex organs

Possibility of Using a New Orally Administered Diuretic "Acetazolamide" in Edema of Pregnancy C. Morra. Minerva ginec. 10:514-523 (July 15) 195 (In Italian) [Turin, Italy].

The author investigated the diuretic action o acetazolamide in women with normal pregnancy and in pregnant women with edema of pregnancy in order to evaluate its application in those in whom edema of pregnancy is the only symptom o in whom edema is associated with other disorder of pregnancy (albuminuria and hypertension). Acetazolamide was given orally to 16 hospitalized primigravidas, divided into 3 groups. One group consisted of 6 women with normal pregnancy; th second group consisted of 6 pregnant women with edema of pregnancy; the third group consisted o 4 pregnant women, in whom edema of pregnancy was associated with albuminuria and hypertension A total dosage of 1,500 mg. of acetazolamide, divided into 4 equal doses, was administered orally to the patients for 4 consecutive days. Urine and blood samples were taken the day before and 40 hours after the beginning of the drug therapy. Women of the first group were kept on a standard diet for pregnant women, whereas the others were kept on a diet low in sodium. Diuresis increased only slightly and for a short period of time in women with normal pregnancy. The excretion of potassium, and to a higher degree of sodium, was proportionally higher than the elimination of water; on the 4th day of treatment the excretion was only slightly higher than before the onset of the drug therapy. It thus became obvious that the body tended to spare and to accumulate water. The body weight of the patients fell insignificantly during this period.

Increase of diuresis was considerable and was prolonged in time in women with edema of pregnancy (groups 2 and 3). Elimination of water and of salts was proportional to their absorption by the organism before the drug therapy. Diuresis reached the highest level on the first day of administration of acetazolamide to women with edema of pregnancy, and it remained at high level for several days. On the 4th day of therapy diuresis decreased slightly and would have continued for several days after the withdrawal of acetazolamide if complete relief of edema had not been obtained during the therapy. The elimination of sodium in patients with edema alone or edema associated with other symptoms (groups 2 and 3) was, in terms of percentage, higher than the elimination of water, and it reached its highest level on the second day of drug therapy. Blood acidosis started to rise gradually from the 1st to the 4th day of treatment with acetozalamide, but it never reached an alarming level. Patients with edema of pregnancy lost 2 to 5 kg. (5 to 11 lb.) in weight after 5 days of therapy. The most advantageous features of acetazolamide therapy in patients with edema of pregnancy appeared to be a prompt, efficacious, and profuse elimination of both water and sodium and the absence of toxic effects on the renal tubules.

An Evaluation of Chlorothiazide in the Treatment of Edema in Pregnant Women. L. C. Chesley and L. Uichanco. Am. J. Obst. & Gynec. 76:467-472 (Sept.) 1958 [St. Louis].

A new diuretic sulfonamide, chlorothiazide (6-chloro-7-sulfamyl-1,2,4 benzothiadiazine-1,1-dioxide), was given to 7 hospitalized pregnant women with edema. The patients treated had been in bed most of the time and on a low-sodium diet for at least 4 days before administration of the drug was started. They were then given 1 Gm. of chlorothiazide per day in 2 divided doses, one in the morning and the other in the early evening, for 6 consecutive days. Chlorothiazide increased the sodium excretion in 6 of the 7 patients studied, although drug resistance developed progressively within a few days. When treatment with the drug was restarted after a 3-day rest, natruresis again occurred in 3 patients. All 7 patients had already lost weight on treatment by bed rest and dietary sodium restriction alone, which had preceded the treatment with chlorothiazide. The good diuretic effect of this previous treatment was also shown by the negative sodium balance still present in the patients when the administration of chlorothiazide was started. These observations suggest that chlorothiazide stimulates sodium and chloride excretion in pregnant edematous women after the major diuretic effect has been achieved by bed rest and low-sodium diet.

PEDIATRICS

Antibacterial Activity of Serum After Oral Doses of Triacetyloleandomycin, Erythromycin, Potassium Penicillin V and Penicillin V. C. M. Kunin, C. V. Pryles and M. Finland. Pediatrics 22:422-431 (Sept.) 1958 [Springfield, Ill.].

Eight normal young men, ranging in body weight from 70 kg. (154 lb.) to 105 kg. (232 lb.), were given in a double, Latin-square rotation an oral dose of 500 mg. of 4 preparations, i. e., pressed tablets of penicillin V, similar tablets of potassium penicillin V, coated tablets of erythromycin, and capsules of triacetyloleandomycin. These were taken 3 or 4 days apart, each with a glass of water a half-hour to one hour before breakfast, and serum was obtained from each patient before and 1, 2, 5, and 8 hours after each dose. All serums collected on each day were assayed simultaneously for activity against Streptococcus 98, Staphylococcus 209 P, and a penicillin-resistant strain, Staphylococcus 400. In a second study, 30 children, between the ages of 2½ and 13 years, ranging in body weight from 11 kg. (25 lb.) to 20 kg. (44 lb.), were divided into 3 comparable groups of 10. The first group was given a suspension of crystalline erythromycin ethyl carbonate, the second received a suspension of triacetyloleandomycin, and a suspension of penicillin V was administered to the third. Doses of 25 mg. per kilogram of body weight were given every 8 hours, and serums for assays were obtained from all 30 children before and 2 and 8 hours after the first dose, and from some on the morning of the 4th day. These serums were all tested for antibacterial action against Streptococcus 98 and Staphylococcus 209 P.

Triacetyloleandomycin produced antistreptococcic and antistaphylococcic activity in the serums of the normal men and of the children comparable to that produced by equivalent amounts of the erythromycin preparations used. The better and more rapid absorption of doses of potassium penicillin V given orally, as compared with acid penicillin V, was confirmed. It was also shown that penicillin V, either as the acid or as the potassium salt, produced significantly higher peak levels of antibacterial activity than either erythromycin or triacetyloleandomycin.

Avitaminosis E in Cystic Fibrosis of the Pancreas: A Morphologic Study of Gastrointestinal and Striated Muscle. W. A. Blanc, J. D. Reid and D. H. Andersen. Pediàtrics 22:494-506 (Sept.) 1958 [Springfield, Ill.].

The authors examined for the presence of ceroid pigment the routine hematoxylin-and-eosin-stained sections of the gastrointestinal tract of 151 children with cystic fibrosis of the pancreas, who had died and on whom autopsies were performed. For control purposes, a similar survey was made of 50 appendixes removed from otherwise normal children, who were above 10 years of age, and of autopsy material obtained from 392 children without pancreatic deficiency, cirrhosis of the liver, or biliary atresia. Fragments of striated muscle obtained from 68 of the 151 children with cystic fibrosis of the pancreas were studied likewise. A diffuse deposition of ceroid pigment was found consistently in the smooth-muscle layers of the gastrointestinal tract of children with cystic fibrosis of the pancreas. The deposition was first seen in children in the 2nd year of life and was frequently extensive in those in the 4th year. It was found in all patients 5 years of age and older, and the amount of ceroid pigment had increased. It has not been observed in other pediatric conditions, with the exception of biliary atresia and cirrhosis of the liver. Extensive deposit of ceroid pigment probably represents an expression of prolonged and severe vitamin E deficiency, related to protracted malabsorption of fat-soluble tocopherols.

Only rare instances of changes in the striated muscles were observed in the children with cystic fibrosis of the pancreas. These changes were inconstant and did not appear to be part of a generalized process. They did not bear any relation to the age of the patient, the severity of the disease, and the amount of ceroid pigment deposited in the smooth muscles.

Cloaca with Non-adrenal Female Pseudohermaphrodism. W. K. Sieber and R. Klein. Pediatrics 22: 472-477 (Sept.) 1958 [Springfield, Ill.].

The authors report on 2 infants who had previously unreported urogenital anomalies. Both patients were females with pseudohermaphroditism of nonadrenal origin who had persistent cloacae. This rare combination of anomalies was recognizable clinically. The causation of the anomalies is unknown. If the diagnosis is made promptly, surgical correction may possibly prevent serious renal damage. It would seem that the surgical approach to this anomaly would be a vaginal-type, pull-through operation in which the vagina would be transposed anteriorly behind the clitoris. This procedure was contemplated in the second infant and was actually performed on the first. The obstruction of the upper portion of the urinary tract was a constant problem in both patients and may have been an indirect cause of death in the second patient. The first patient has urinary incontinence and reduced renal function but is alive at 6 years of age.

DERMATOLOGY

Acute Peptic Ulcer After Triamcinolone Therapy: Report of Three Cases. C. H. Brown and J. R. Haserick. A. M. A. Arch. Dermat. 78:289-292 (Sept.) 1958 [Chicago].

The role of steroids in the pathogenesis of peptic ulcer is not clear. In a small percentage of patients the development of peptic ulcers, both gastric and duodenal, has been an unfortunate sequela of steroid therapy. No matter which cortisone or cortisone-like drug is used, the incidence of ulcer does not seem to vary. In general, peptic ulcer develops more frequently in patients who have been given large doses of steroids for relatively long periods of time. It has been the authors' experience that the majority of patients in whom "steroid ulcers" develop have previously had peptic ulcers or have some other contributing condition, such as duodenal stasis associated with mesenteric root compression. The authors, and also other workers, have been able to give steroids safely to patients who have previously had peptic ulcers by combining simple ulcer treatment with steroid therapy, and patients so treated have had no recurrence of the ulcers. Various workers have reported a low incidence of peptic ulcers in patients receiving triamcinolone (Aristocort).

The occurrence of an acute duodenal ulcer in one patient within a short time after the start of treatment with small doses of triamcinolone and the development in 2 other patients of ulcer associated with triamcinolone therapy seem to be of interest. The first patient, a 41-year-old man, had had psoriasis for 12 years. He had no gastrointestinal symptoms when first admitted to the Cleveland Clinic Hospital, nor did his history reveal any ulcer or digestive disease. Typhoid vaccine was administered intravenously, and he was instructed to follow the Goeckerman regimen. Improvement in his psoriatic condition resulted from this treatment, and he was discharged from the hospital Four and one half years later in acute flare-up of the psoriasis led to the use of triamcinolone in treating this patient. Twenty-one days later he passed 2 tarry stools and complained of having had intermittent, recurrent epigastric pain for several days. He was then readmitted to the hospital for diagnosis and treatment. Palpation of the abdomen disclosed localized tenderness that was restricted to a small area in the epigastrium and the right upper quadrant. No masses were palpated, and there was no muscle spasm. The other physical findings, including those of the heart, lungs, and rectum, were normal. Roentgenograms after barium swallow showed the esophagus and the stomach to be normal. There was a slight deformity of the duodenal bulb, and a large ulcer crater was visible on the posterior wall of the bulb. The epigastric pain disappeared within 24 hours after ulcer therapy was instituted, although the patient surreptitiously continued to take 8 mg. of triamcinolone daily for one week. The rapidity with which ulcer developed with small doses of this drug suggest that in this patient the steroid may have been ulcerogenic. Symptoms of ulcer did not appear in the other 2 patients until 6 weeks after the start of triamcinolone treatment.

This experience suggests that the same precautions against ulcer should be taken with triamcinolone as with other steroids. Any patient who has had an ulcer should follow at least a simple ulcer program while under treatment with steroids. Many patients with steroid ulcers do not present the classic symptoms of peptic ulcer but rather those of the complications of ulcer, such as massive bleeding or perforation or both. The possibility that a peptic ulcer that is symptomatically atypical may occur in patients treated with steroids should be kept in mind.

Oral Treatment of Keloids. E. W. Kelly Jr. and H. Pinkus. A. M. A. Arch. Dermat. 78:348-352 (Sept.) 1958 [Chicago].

A form of systemic therapy for keloids, which would be free from the drawbacks of the corticosteroids and which would make it possible to avoid the disagreeable features and shortcomings of local injections, surgery, or irradiation, would be highly desirable. Experience with tetrahydroxyquinone (THQ) in 45 consecutive patients has shown that this drug may cause some regression in keloids of as much as 40 years' duration and may produce complete resolution in some younger lesions. It relieves the pain and pruritus often associated with keloids promptly, but the objective regression of the lesion is slow. No side-effects or untoward reactions have been observed, and the drug has been proved nontoxic in animal experiments in which enormous doses were used. The only undesirable reaction encountered has been the occasional local breakdown of keloid tissue accompanied by the discharge of necrotic material. This apparently results from the softening of the tissue around old devitalized collagen bundles and is actually a sign of effectiveness of the treatment. The action of THQ is selective. Biopsy specimens from the normal skin of persons under treatment with THQ showed none of the changes seen in the treated keloid. The question, therefore, arises: What is it in the keloid that is controlled by this redox-active drug? Alteration of redox potentials in the tissue is a possibility. Action on enzyme systems seems another. The enzymes of the dermis have not been studied to any great extent by histochemical means. In a few preliminary studies, the authors observed esterase-positive granules in mast cells. Investigation of the changes that may occur in the dermal enzymes during treatment with THQ would apparently be worthwhile and might help to explain its favorable effect on keloids.

Cutaneous Reactions Due to Sulfamethoxypyridazine. D. G. Lindsay, I. Prlina, A. J. Bischoff and S. W. Becker Sr. A. M. A. Arch. Dermat. 78:299-303 (Sept.) 1958 [Chicago].

Cutaneous reactions, ranging from mild eruptions to severe generalized dermatitis, appeared in 6 of 55 hospitalized patients and in 7 of 30 ambulatory patients, all of whom were being given sulfamethoxypyridazine (SMPZ). This drug, which has been found effective in patients with urinary tract infection, is readily absorbed from the gastrointestinal tract and is slowly excreted in the urine. Its antibacterial effectiveness is comparable to that of sulfadiazine. The occurrence of erythematous maculopapular dermatitis after its administration, therefore, seems to be of interest. The previous administration of sulfonamides apparently does not influence the incidence of reactions, but it does seem to determine the time of their onset. In general, if a reaction is going to occur, it will appear within 1 to 5 days in patients who have previously received sulfonamides, whereas in those not previously given sulfonamides the reaction often appears on about the 14th day. In 5 of the 13 patients with toxic reactions to SMPZ, the dermatitis appeared in about 2 weeks. Four of these patients, all of whom had received 1 Gm. or more of the drug daily, gave no history of previous treatment with sulfonamides. In 6 other patients, 4 of whom had previously taken sulfonamides, the reactions developed in less than 7 days. Dermatitis appeared in the remaining 2 patients, neither of whom had previously been given sulfonamides, 9 days and 42 days, respectively, after they began to take 1 Gm. of SMPZ daily. The occurrence of untoward reactions is apparently related to the amount of the dose in some patients, but not in all. Thus, only 2 of the 30 patients receiving 0.5 Gm. daily showed an untoward reaction, as compared with 11 of the 55 patients receiving 1 Gm. or more a day.

Daily serum SMPZ determinations did not show a gradual increase with time at a constant dosage but averaged about 10 mg. per 100 cc. in patients taking 1 Gm. daily and about 5 mg. per 100 cc. in those taking 0.5 Gm. daily. There were wide variations from these mean values, however; no correlation could be made between the occurrence of reactions and the serum SMPZ levels because of an insufficient number of determinations. To prevent severe reactions, sulfonamide therapy should be stopped at the first sign of trouble. Most of the reactions in these patients were mild, but in 1 of the 2 patients who received the largest total dosage the dermatitis became so severe and extensive that he appeared moribund 6 days after its onset. Vigorous treatment with corticosteroids (hydrocortisone, corticotropin, and prednisolone) and antibiotics (penicillin and streptomycin) eventually overcame the reaction, and by the time the patient was discharged from the hospital, 6 weeks after the dermatitis appeared, all the skin lesions had healed.

Changes in the Skin as a Result of Electric Current. L. H. Winer and G. H. Levin. A. M. A. Arch. Dermat. 78:386-390 (Sept.) 1958 [Chicago].

Clinically, electric burns can vary in degree from a superficial erosion to a charred, bullet-hole-like wound. The histopathological changes in the epidermis are striking. Noteworthy are (1) the production of bundles of vacuolated spindle-shaped cells, (2) the separation of epidermis from cutis, (3) coagulation of collagen of the cutis, (4) cavity formation in the cutis and deposition of nests of epidermal cells, and (5) retention of hair follicles. The absence of cellular inflammatory reaction is remarkable. These changes were evident in a specimen removed from a 20-year-old youth who died after accidental electrocution by 5,000 volts of high-tension electric current. The skin lesion was 3 in. in diameter on the forearm and was charred. The specimen removed for microscopic examination was sectioned and stained with hematoxylin and eosin. It was denuded of epidermis. The connective tissue fibers in the cutis were fused together in a solid mass which stained dark red. The blood vessels within this mass were thrombosed, and in some areas free hemorrhage occurred into large cavities of the dermis. Elastic resorcin staining revealed an intense increase in elastic-like fibrils which were definitely fragmented. On Mallory staining, the degenerated collagen, in its more superficial areas, was dark red; deeper in its midportion it was violet; and in its depths, just above the fatty tissue, it stained its normal blue color. The replacement of the normally blue-staining collagen with red-staining fibers supports the assumption that the electric current produced a large mass of elastic fibers. This increase in elastic fibers, together with degeneration of the collagen, is noteworthy because it is not seen in pure thermal burns. Moreover, the elastic fiber increase probably accounts for the soft, noncontractible scar with which electric burns heal.

OPHTHALMOLOGY

A Report on the Attempted Isolation of the Virus of Trachoma. C. H. Smith, M. J. Gilkes and J. Sowa. Brit. J. Ophth. 42:461-472 (Aug.) 1958 [London].

The authors report on various attempts made to isolate the virus of trachoma in Jordan and Gambia, where the disease is endemic and a large proportion of the population is infected, and in London, where occasional cases were observed in the outpatient departments of Moorfields Hospital in patients who had been infected before arriving in England. Specimens for isolation of the virus were taken from the conjunctiva of the infected persons by means of a spatula made from aluminum wire. *It proved impossible to isolate trachoma virus in* HeLa cells, conjunctival cells, mice, or chick embryos. Although there was some delay between the taking of scrapings and the inoculation into animals or tissue cultures, it seems unlikely that time alone was sufficient to inactivate the inoculums. It is possible that the virus was not cytopathogenic or inclusion-producing in tissue culture or that it was incapable of entry into the cells of the culture. It may also be possible that the inclusions found in superficial cells represented an "incomplete" viral form, the limited metabolism of these superficial cells preventing complete development of the virus. The administration of antibiotics to the patients from whom the specimens for isolation of the virus were obtained might have increased the difficulties of isolation of the virus in tissue cultures. Viruses do not always multiply in the tissue apparently most closely resembling that from which they are isolated; thus, cytomegalic inclusion virus grows in fibroblasts, and certain enteric cytopathogenic human orphan (ECHO) viruses from human sources will not multiply in human cells. Hence, it may be necessary to obtain completely fresh cell lines, and this would seem to be one of the most fruitful approaches to the problem of isolating the trachoma virus.

Retrolental Fibroplasia in Association with Mental Defect. C. E. Williams. Brit. J. Ophth. 42:549-557 (Sept.) 1958 [London].

Retrolental fibroplasia is a major cause of blindness in premature children. The incidence of mental defect in premature children has been variously estimated as between 4 and 10%. The incidence of severe mental defect in children with retrolental fibroplasia has varied from 10 to 40% in different investigations. The author was able to review the admissions to and the discharges from the Sunshine Homes over the past 10 years. These homes admit about one-third of the blind children in England and Wales for care and early training. At least 50% of the children discharged from the Sunshine Homes as "ineducable" between 1950 and 1956 suffered from retrolental fibroplasia. The author found that, of a total of 24 children with retrolental fibroplasia, 23 had been born prematurely. A history of being nursed in oxygen tents was available for 18 of them; for 4 there was no such history, but they were born at a time when it was routine to nurse premature infants in high concentrations of oxygen; and 1 child received oxygen by nasal catheter at meal times. The one child with retrolental fibroplasia who had not been born prematurely had not received oxygen; in this child the etiology remained unexplained. The degree of mental defect was not related to the duration of oxygen therapy. There were no cases of cerebral palsy in the series, but 2 children had congenital heart lesions and in 6 children there was a history of antepartum hemorrhage during the mother's pregnancy. The incidence of mental defect in cases of retrolental fibroplasia appears to be greater than could be explained by the factor of prematurity.

THERAPEUTICS

Chloropropamide: A New Hypoglycaemic Agent. I. Murray, M. J. Riddell and I. Wang. Lancet 2:553-554 (Sept. 13) 1958 [London].

The results obtained by giving chlorpropamide [N-propyl-N-(*p*-chlorobenzene sulfonyl) urea], a new preparation, to 43 patients showed it to be an effective oral hypoglycemic agent in the treatment of diabetes. Its action, however, like that of similar drugs, is somewhat unpredictable. The patients selected for this trial were essentially of the type considered most suitable for oral therapy, i. e., they had had diabetes for less than 10 years, were over 40 years old, and had taken insulin, if at all, for not more than 2 years. Only 2 patients were obese, although 17 others had been so. Diet alone had not controlled the diabetes sufficiently. The initial dose of chloropropamide as in the authors' original investigation of carbutamide, was 1 Gm. daily at breakfast, but no loading dose was given in the first 2 days of treatment. The response to this dose of 1 Gm. daily was satisfactory in 28 of the 43 patients treated. These 28 patients, who constituted the successes, were similar as a group to the remaining 15, who were the failures, except that ketonuria had previously been noted in 4 (27%) of the failures as compared with only 1 (4%) of the successes. In the successes, a satisfactory response was evident generally by the 2nd or the 3rd day and always within 7 days (mean, 3.2 days), all 3 of the daily urine tests being recorded as "blue" or, at worst, showing an occasional trace (0.25%). Some of the patients had previously received carbutamide or tolbutamide. Comparison of the results obtained by the use of these drugs with those obtained by the use of chlorpropamide produced the impression that chloropropamide is somewhat less potent than carbutamide, but definitely more potent than tolbutamide.

The dose of chlorpropamide was increased in 5 patients who did not respond well to 1 Gm., 4 receiving 2 Gm. daily and 1 receiving 3 Gm. The increased dosage resulted in satisfactory control in 3 of these patients, but since the possibility of side-effects makes the administration of more than 1 Gm. of chlorpropamide a day inadvisable, these cases were listed as failures. No serious toxic effects were noted, nor was there any evidence of either leukopenia or thrombocytopenia, but 7 patients suffered from nausea (insufficient to call for abandonment of treatment); 1 had a diffuse erythematous rash; and 1 showed drowsiness unaccompanied by hypoglycemia. The occurrence of these side-effects, which appeared in 4 cases after the dosage had been increased to 2 Gm., suggests that the dose should not exceed 1 Gm. daily and that smaller doses should be used when possible. Satisfactory results have already been obtained with 0.5 Gm., but further experience is required before the best dosage can be decided on. Provisionally, treatment may be begun with a single dose of 1 Gm. a day, to be reduced to the lowest level found effective as soon as a good result is obtained.

PATHOLOGY

Leukocyte Sedimentation Rate in Patients with Lymphosarcoma, Reticulosarcoma and Malignant Lymphogranuloma. L. Bellesia, E. Lusvarghi and C. Pasquinelli. Minerva med. 49:2856-2861 (July 21) 1958 (In Italian) [Turin, Italy].

The authors studied the leukocyte sedimentation rates, according to the technique devised by Storti, in 58 patients with either lymphosarcoma, reticulosarcoma, or Hodgkin's disease. The patients were divided into 2 groups; one group had previously been given chemical or roentgen-ray antineoplastic therapy, but the other had not. Of the 38 patients in the latter group, 12 had either lymphosarcoma or reticulosarcoma, and 26 had Hodgkin's disease. Hodgkin's disease was in remission in 13 patients and in the process of first manifestation or reactivation in the remaining 13. Of the 20 patients who were receiving chemical or roentgen-ray treatment at the time of this study, 10 had either lymphosarcoma or reticulosarcoma, and 10 had Hodgkin's disease. The leukocyte sedimentation rates were within normal values and the Katz formula levels were increased among the patients with lymphosarcoma or reticulosarcoma who had not previously received antineoplastic therapy. These values varied similarly among the patients with Hodgkin's disease, both the leukocyte sedimentation rates and the Katz formula levels being within normal limits when the disease was subsiding and being elevated when the disease was in progress or in process of reactivation. The leukocyte sedimentation rates, unlike the Katz formula levels, did not change in patients with either lymphosarcoma or reticulosarcoma who were receiving chemical or roentgen-ray antineoplastic treatment. At the end of treatment, though, the leukocyte sedimentation rates returned to within physiological limits at a rate similar to, or slightly faster than, the Katz formula levels in patients with Hodgkin's disease in progress or in process of reactivation.

The leukocyte sedimentation rate seems to have a diagnostic value in differentiating lymphosarcoma and reticulosarcoma from Hodgkin's disease. This is particularly true during the first manifestation of the disease and when a diagnostic biopsy yields little information. The error in establishing a correct differential diagnosis by the leukocyte sedimentation rate varied within a margin of 5%. The high leukocyte sedimentation rate in Hodgkin's disease during the first manifestation or reactivation of the disease and the presence of a normal level when the symptoms of the disease are in remission are reliable clinical aids for differentiating the reactivated from the dormant phase of the disease. The erythrocyte sedimentation rate also serves well as a test, although its level, unlike that of the leukocyte sedimentation rate, may be affected by the presence of anemia or of an imbalance in the serum protein level. The leukocyte sedimentation rate can be useful during chemical or roentgen-ray antineoplastic treatment of Hodgkin's disease. A high leukocyte sedimentation rate at the termination of a course of antineoplastic treatment would suggest continuation of the treatment. If the leukocyte sedimentation rate returns to normal limits in the course of antineoplastic treatment, it may be advantageous to withdraw the specific treatment, since it has reached the useful therapeutic dosage.

Hypertensive Vascular Disease as a Consequence of Increased Arterial Pressure: Quantitative Study in Rats with Hydralazine-Treated Renal Hypertension. G. M. C. Masson, L. J. McCormack, H. P. Dustan and A. C. Corcoran. Am. J. Path. 34:817-833 (Sept.) 1958 [Ann Arbor, Mich.].

The quantitative associations between levels of arterial blood pressure and the occurrence and character of hypertensive vascular lesions (myocardial, mesenteric, and pancreatic) were tested in rats subjected to partial renal infarction and unilateral nephrectomy. The levels of blood pressure were controlled by the administration of hydralazine in drinking water. This mode of administration of the drug was found to secure stable control of blood pressure at normal levels in most animals. In experiments of short duration (7 to 14 days), acute vascular lesions were found in the majority of animals with untreated hypertension. These were largely prevented by maintenance of blood pressure within a normal range and, when they had been allowed to develop, were found to lose their acute characteristics when remission of hypertension was induced by hydralazine. A similar sequence was established in experiments of longer duration (1 to 2 months). The latter experiments also showed that control of renal hypertension by a drug for one month did not prevent the onset of severe hypertension and vascular lesions when the drug was withdrawn. The data demonstrated a close association between blood pressure levels and the presence and character of the vascular lesions. The observations confirm the view that mesenteric "arteritis" of rats with hypertension is in fact an expression of hypertensive vascular disease.

The sensitivity of the renal vascular bed to hypertension was demonstrated in a group of hypertensive, hydralazine-treated rats which showed slight extrarenal vascular alterations but, in some cases, severe and apparently progressive lesions in renal vessels. In accordance with previous clinical observations, treatment of renal hypertension in rats did not restore heart size to normal. On the contrary, continuous treatment with hydralazine in doses sufficient to prevent the onset of hypertension was found to increase heart size, presumably as a result of increased heart rate and output.

RADIOL

Angiocardiographic Features Garland Syndrome. E. K. Lang, L. J. G. Mcafee. Am. J. Roentgenol. 80: 1958 [Springfield, Ill.].

Anomalous origin of the left coronary from the pulmonary artery (Bland-White-Ga syndrome) has been recognized clinically with creasing frequency in recent years. All 62 patients with this condition, whose cases were collected from the literature, died. Of the 62 patients, 50 were infants and 12 were adults. The anomaly involved the left coronary artery in 44 infants and both coronary arteries in 6 infants. In 9 adult patients the anomaly involved the left coronary artery, and in only 3 the right coronary artery. In the adult patients the anomalous origin of the coronary arteries either was an incidental postmortem finding or was observed at autopsy in those who died suddenly without preceding symptoms. Chest roentgenograms were obtained in 24 of the 44 infants and they showed marked cardiac enlargement with left ventricular preponderance.

The authors report on 4 infants with proved anomalous origin of the left coronary artery in whom a characteristic picture was found on angiocardiography. The angiocardiographic findings in these patients suggest that, with the intravenous injection of a radiopaque material, visualization of all the cardiac chambers is good despite the marked cardiac enlargement and slow circulation time, because of the absence of intracardiac shunts. The right chambers are usually normal in size, but the right ventricle is often displaced to the right and compressed anteriorly against the sternum by the grossly enlarged left ventricle. The posterior and left margins of the right ventricle are rendered concave by the bulging ventricular septum. The pulmonary artery and its branches usually appear normal. Opacification of the left coronary artery from the pulmonary artery is not seen. The left atrium may be normal or slightly enlarged; more marked degrees of enlargement should suggest mitral stenosis. It is often displaced to the right and superiorly by the large left ventricle. It may be rotated so that its left side is higher than the right. The left ventricular chamber usually remains opacified for a prolonged period because of its huge size and because of the slow circulation time. When rapid serial roentgenograms are obtained at the rate of 4 to 6 frames per second, the absence of effective systolic contractions is apparent. The hypertrophied left ventricular wall is seen at the base of the heart in the anteroposterior views, and in the ventricular septum in the lateral views. In contrast, the apical region shows marked thinning of the wall; its actual measurement in the roentgenogram does not exceed 2 or 3 mm. As a result of this thinning, the opacified left ventricular cavity develops a rather pointed and localized bulge at the apex. The aorta appears normal. Differential diagnosis between the Bland-White-Garland syndrome and other conditions producing left ventricular enlargement in infants can usually be made angiocardiographically by the characteristic thinning of the myocardium near the apex and by the absence of pulsation of the huge left ventricle.

Three of the 4 infants in the authors' series died, but cardiopneumopexy with phenol de-epicardialization and talc poudrage saved the life of the 4th patient, in whom the clinical findings, in conjunction with the angiocardiogram and the electrocardiogram, established the diagnosis of anomalous left coronary artery arising from the pulmonary artery. The characteristic picture found on angiocardiography in the 4 infants promises to be a valuable adjunct in diagnosis.

The Role of Aortography in the Determination of Operability in Arteriosclerosis of the Lower Extremities. E. J. Wylie and L. Goldman. Ann. Surg. 148:325-342 (Sept.) 1958 [Philadelphia].

With increasing interest in the surgical treatment of peripheral arteriosclerosis, there have been numerous inquiries concerning the place that aortography should occupy in the preoperative evaluation of patients presenting clinical manifestations of chronic arterial occlusive disease in the lower extremities. The 3 issues upon which attention has been focused involve the extent to which aortography may supplement clinical findings, the practical value of such information, and the complications that aortography may cause. To clarify these issues, the authors reviewed the records of 500 patients with arteriosclerotic obstruction involving arteries supplying the lower extremities, on whom aortography was performed. The site of injection was the upper abdominal aorta in 290 patients and the lower abdominal aorta in 210 patients. The lower level has become the site of choice for all studies except those in which clinical findings have indicated thrombosis of the abdominal aorta. Simultaneous injection through two 17-gauge needles permitted the rapid introduction of an adequate bolus of the medium, thus eliminating the possibility of hemorrhage that might have occurred if a single needle of larger caliber had been used. It was found that aortography added surgically significant supplementary information to the purely regional localization of arterial occlusion that had been determined by prior clinical examination. The information obtained proved valuable in the final determination of operability and in the selection of the site and method of operation.

PUBLIC HEALTH

An Outbreak of Pharyngoconjunctival Fever Caused by Types 3 and 4 Adenovirus at Waalwijk, The Netherlands. J. van der Veen and G. van der Ploeg. Am. J. Hyg. 68:95-105 (Sept.) 1958 [Baltimore].

This report is concerned with a localized epidemic of pharyngoconjunctival fever in The Netherlands in 1957. The outbreak occurred at Waalwijk, a town with a population of about 16,000. In July, 1957, one of the Waalwijk physicians reported that he was seeing cases of illness characterized by fever, pharyngitis, and conjunctivitis among school children. Within a few days a sharp increase in the number of cases was observed. Through the cooperation of practicing physicians and the school medical officer, the authors were able to study this outbreak. They made studies on 65 patients. The outbreak appeared to be due to adenovirus, types 3 and 4. Type 3 was isolated from 46 patients, and type 4 from 11 patients. Types 2, 5, 7, and 9 were recovered from sporadic cases of pharyngoconjunctival fever. In 63 cases both throat swab and stool were examined for adenovirus content; the stool appeared to be a better source of virus than the throat swab. About two-thirds of the cases occurred among school children, 8 to 14 years of age. Boys were attacked at a higher rate than girls. The epidemiologic observations are discussed with respect to the probable relationship of illness and irritation of the nasal and conjunctival mucosa from swimming and outdoor activities.

Adenovirus Infections in Children and Young Adults: With Comments on Vaccination. A. S. Evans. New England J. Med. 259:464-468 (Sept. 4) 1958 [Boston].

The author reports a study on 710 university students admitted to the infirmary of the University of Wisconsin between 1954 and 1958 with symptoms of acute respiratory disease. In 10% of the patients the symptoms were due to bacteria, in 10% to known viruses, and in 80% to unknown conditions. Only 7 adenoviruses were isolated, a rate of 1%: types 1, 3, 4, and 6 were identified. According to these findings, about 1 university student per 5,000 acquires a clinical illness due to adenovirus each year. A similar picture was observed in presumably healthy third-graders, aged 7 to 9 years, attending 3 public schools. Only 3 adenoviruses were isolated from 1,194 swabs obtained from 291 of these pupils. Because of these findings vaccination of the general public against adenovirus infections is not recommended. It is, however, recommended in military recruits and in persons who have intimate and prolonged contact with one another, such as inmates in mental hospitals, tuberculosis sanatoriums, and homes for the aged.

BOOK REVIEWS

Infectious Diseases of Children. By Saul Krugman, M.D., Associate Professor of Pediatrics, New York University College of Medicine, New York, and Robert Ward, M.D., Professor and Head of Department of Pediatrics, University of Southern California, Los Angeles. Cloth. $10. Pp. 340, with 51 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1958.

The material covered in this book covers those viral, rickettsial, and bacterial infections currently met by practicing physicians in the home, office, and hospital. The chapters on the Coxsackie virus infections, viral hepatitis, influenza, acute bacterial meningitis, rubella, staphylococcic infections, toxoplasmosis, and communicable disease control, are particularly good. The one on staphylococcic infections is especially timely. The treatment of pregnant women with rubella is explained well. The value of the text would have been enhanced if an introductory chapter had been written giving current knowledge of means of isolating, identifying, and culturing bacterial, rickettsial, and viral organisms. The color plates, schematic drawings, and graphs are very well done. The text is recommended for use by the general practitioner, pediatrician, internist, and health officer.

Life Insurance and Medicine: The Prognosis and Underwriting of Disease. Edited by Harry E. Ungerleider, M.D., F.A.C.P., Director of Medical Research, Equitable Life Assurance Society of United States, and Richard S. Gubner, M.D., F.A.C.P., Clinical Associate Professor of Medicine, State University of New York College of Medicine, Brooklyn. Cloth. $16.50. Pp. 994, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill., Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1958.

This book is a compilation of lectures and papers dealing with many aspects of life insurance and related topics. The 56 contributors are recognized authorities in life insurance and related fields. The text is divided into four parts. Part 1 deals with the fundamentals of life insurance. It explains not only the principles of life insurance, organization of companies, the various forms of life insurance, mortality tables and statistics, risk selection, and reinsurance but also such topics as inspection reports, internal organization of life insurance companies, the legal phases, and health insurance. Although part 2 is captioned, "Non-Medical Aspects," there are several interrelationships mentioned that involve various elements of the medical profession. These chapters deal with history and philosophy of life insurance, the relationship of longevity to insurance selection, mortality tables, numerical ratings with respect to underwriting, nonmedical underwriting, biological and social factors that influence life insurance selection, the relationship between the life insurance medical director and physicians in private practice, medical forms, medical examiners and their selection, and the internal organization of a life insurance company medical department.

To those who feel that life insurance medical directors dwell in a world apart from clinicians, part 3, entitled "Medical Aspects," makes it clear that medical directors must not only keep abreast of clinical medicine but also be able to translate these developments into their effects on risk selection, morbidity, and mortality. Impaired risks are discussed and several chapters are devoted to such diseases as diabetes, hypertension, hepatic disorders, and neoplasms. The two chapters in part 4 deal with various facets of accident and health insurance including the relatively new type of coverage called major medical. The essential differences between accident insurance and health insurance are discussed including both underwriting and claims processing. Many life insurance companies write a substantial volume of accident and health insurance, certain phases of which depend on medical evaluation. For the most part the text is well presented and edited. There are, however, a few typographical errors. For example, on page 186 in a discussion on life insurance contract clauses, it is stated "that the policy will be incontestable for two years. . . ." The text should indicate either that the policy is incontestable after two years or that it is contestable only during the first two years. This book, which is well indexed, is a valuable source and reference text covering a wide range of topics. It is recommended for those who desire broader understanding of the many responsibilities of life insurance medical directors and the interdependence between medical directors and physicians in private practice.

Diseases of the Thyroid and Parathyroid Glands. By Bernard J. Ficarra, A.B., Sc.B., M.D. Cloth. $8.50. Pp. 295, with 131 illustrations. Intercontinental Medical Book Corporation, 381 Fourth Ave., New York 16, 1958.

The following quotation from the author's introduction correctly describes this work: "This volume . . . has been published not because it is believed to contain any new revelations for the master thyroid surgeon but because it contains factual knowledge on thyroid diseases which should be made known to the general surgeon interested in thyroid

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

surgery. This book, therefore, is the literary product of a general surgeon who is interested in, manages, and operates upon patients with surgical disorders of the thyroid gland. It is an accumulation of knowledge gained by an average general surgeon, with an average surgical practice, in an average American community." This scholarly little book gives the chronological résumé of the history of thyroid and parathyroid diseases from 1600 to 1954. The bibliography is extensive and carefully selected. The emphasis on the pituitary thyrotrophic hormone is justifiable but the use of the abbreviation "anteritary" for anterior pituitary is not. In the theoretical discussion of the cause of exophthalmic goiter the conclusion that there is insufficient thyroid secretion to inhibit TSH production seems contradictory. It appears more likely that it is the failure of an excess of thyroid secretion to inhibit the hypothalamus that causes the disease.

From the internist's point of view this book fails to make clear that the proper treatment of nontoxic goiter is medical, and that of toxic goiter uses radioactive iodine. The discussion of isotope treatment is condensed in one short paragraph referring to a series of 22 patients. Since 1,500 such patients were reported in 1953, three years before this book was written, this seems inadequate. The management of postoperative parathyroid tetany, a lifelong disease occurring after surgical treatment of hyperthyroidism that the internist inherits from the unsuccessful surgeon, is also inadequately treated. This is nevertheless a valuable book, presenting the surgical approach to hyperthyroidism, a good chapter on exophthalmos, and a brief discussion of hyperparathyroidism.

Physical Diagnosis. By F. Dennette Adams, M.D. [Originally written by Richard C. Cabot, M.D.] Fourteenth edition. Cloth. $12. Pp. 926, with illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1958.

This well-known book has been enthusiastically accepted by physicians and students throughout the world. This edition is even more complete than its predecessors and definitely a correlative textbook, since the author has written a good synopsis of clinical diagnosis with special emphasis on the physical diagnostic signs and symptoms of disease. The general motif of the book consists of a thorough discussion, with multiple illustrations, of the techniques of physical diagnosis and of good history-taking. The author has then proceeded to explain the application of these techniques to each anatomic system, and correlated the physical signs with the anatomic and physiological alterations of the pathogenetics of the diseases discussed. He has included the laboratory data and x-ray findings wherever they are applicable. The illustrations are excellent. After discussion of each system's diseases, the author has outlined the pertinent differential diagnoses. The book is designed primarily for the medical student but it should be of great value to the neophyte physician, and even the seasoned physician may find in it many useful reminders. Reading so complete yet concise, accurate, and well-documented a book is in itself a great pleasure.

Hermaphroditism, Genital Anomalies and Related Endocrine Disorders. By Howard W. Jones, Jr., M.D., Associate Professor of Gynecology, Johns Hopkins University School of Medicine, Baltimore, and William Wallace Scott, M.D., Ph.D., Professor of Urology, Johns Hopkins University School of Medicine. Cloth. $16. Pp. 456, with 466 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1958.

Jones, Scott, and an authoritative group of contributing authors have furnished a most important and greatly needed account of the problems of intersexuality, including medical, surgical, embryologic, and psychiatric aspects. The recent interest on the part of both the laity and the medical profession in the physical and psychological problems of intersexuality should be adequately satisfied by this contribution. In 1937, the late Hugh H. Young published a classic monograph entitled "Genital Abnormalities, Hermaphroditism and Related Adrenal Disorders." The supply of this work was quickly exhausted. So much has been learned about the adrenal and its function since Dr. Young's contribution that there has developed a real demand for just such an up-to-date summary of accumulated knowledge as is now presented. Using Dr. Young's background of material, including the inimitable drawings of William Didusch, Dr. Jones, a gynecologist, and Dr. Scott, a urologist, have compiled a text which comprises all that is known and accepted on the cause and treatment of abnormalities of sexual development. The chapter on the origin of the concept of hermaphroditism in Graeco-Roman culture gives evidence of profound research and deserves its place in the histories of mythology and sculpture as well as medicine. A chapter on the recent advances in the determination of sex from a genetic standpoint by Jost should serve as a guide from both a legal and medical point of view. True hermaphroditism, a rare condition, is discussed in great detail. Only 60 authenticated cases have been reported in the past 100 years. Gonadal aplasia and dysplasia, Klinefelter's syndrome, male hermaphroditism, and female hermaphroditism due to congenital adrenal hyperplasia are thoroughly discussed from both scientific and practical aspects. Endocrine tumors of the testis, feminizing adrenal cortical tumors in males, and the radiologic diagnosis of adrenal tumors are illustrated by case reports and clinical data. Surgery of the adrenals is well described. This monumental contribution on an unusual but interesting group of subjects should stand as authoritative for many years.

QUESTIONS AND ANSWERS

CHEST X-RAYS FOR SCHOOL PERSONNEL

To the Editor:—*The problem of regular chest x-rays for personnel who work intimately with children in the schools has come up this year. Present practice includes the submission of a report of negative chest x-ray findings by Nov. 15 of each year. The teacher (or classified employee) may submit a report of current negative results on skin testing for tuberculosis in lieu of the chest x-ray report if he so desires. Of course, if the skin test shows positive results, he will have to go through with the x-ray anyway. Are there any recent developments which might provide a better approach to this problem of adequately safeguarding the children? Are there any comments —pro or con—on the approach here outlined?*

H. Veazie Markham, M.D., Torrance, Calif.

Answer.—The practice of requiring school personnel to submit evidence of freedom from active tuberculosis as a condition of employment is growing in the United States. Such procedures not only safeguard the health of children but also promote the fitness of school personnel. The procedure of requiring a negative finding on skin test for tuberculosis or a chest x-ray when this is known to be positive seems to be in keeping with present recommended practices. In some places, the routine chest x-ray is preferred because it may disclose other conditions, as well as being helpful in tuberculosis case finding. Also, when the incidence of tuberculosis in an area is relatively high, routine chest x-ray may be the most economical approach. Since local conditions and recommendations vary, consultation with state and/or local health departments, tuberculosis association, and medical society is recommended. Local understanding and interpretation, as well as clarification of procedures, will be furthered through this process. Regardless of method, it is well to include in an accompanying educational campaign reassurance as to the use of x-ray in the process. Misleading statements have been made, and misinterpretations of factual observations have aroused needless fears concerning the medical use of x-rays. It is, therefore, important to point out that only minute amounts of radiation are employed and that these are very unlikely to reach the gonads. One wonders about the Nov. 15 date mentioned in the question. For purposes of administration, as well as protection of children and associates, the opening date of school in the fall might be a more satisfactory deadline.

DUODENAL ULCER AND BILIARY TRACT DISEASE

To the Editor:—*Is there any possibility that the development of a duodenal ulcer could be caused or contributed to by previous biliary tract disease or biliary tract surgery?*

J. Manly Bryan, M.D., Canyon, Texas.

Answer.—Previously, it was believed and taught that duodenal ulcer and gallbladder disease did not exist in the same individual because of varied constitutional characteristics for each of the two diseases. This is an error; the two diseases do coexist in the same person, and, when they do, it is usually the ulcer and not the gallbladder that is responsible for the symptoms. The mere fact that gallstones or cholecystitis is present in a patient with ulcer does not signify that the gallstones or the gallbladder disease is causally related, but at times the inflamed gallbladder may become adherent to the duodenum. Apart from the mechanical contiguity, there is no etiological relationship between the two diseases. The inflamed gallbladder does not aggravate the ulcer, nor does the ulcer have any relationship to the gallbladder. At times the gallbladder may perforate through the second portion of the duodenum (even resulting in gross hemorrhage). It is through this fistulous opening that large gallstones make their way into the small intestine and eventually cause a gallstone obstruction.

As for biliary tract surgery, a persistent external biliary fistula surgically treated for the relief of biliary obstruction might divert enough of the alkaline pancreatic juices from the duodenum as to make possible the formation of a duodenal ulcer.

Answer.—There seems to be no definite evidence that previous biliary tract disease or biliary tract surgery has anything to do with the development of a duodenal ulcer. Occasionally, a roentgenologic deformity of the duodenum resembling a duodenal ulcer may be reported in persons who have had previous biliary tract surgery, and a duodenal ulcer may be associated with biliary tract disease. Occasionally, at the time of abdominal exploration, the deformity has been found to be due to adhesions between the gallbladder area and the duodenum and a true ulcer does not exist. The

Anonymous communications cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

deformity has been noted to disappear when the adhesions were cut. While duodenal ulcer and biliary tract disease may be found in the same individual, there is no definite evidence that the ulcer is the result of biliary tract disease.

HEADACHES

To the Editor:—*A 48-year-old man complains of intense headache during coitus. The severity of the headache begins to subside about five minutes after orgasm. Occasionally, the headache is experienced with bowel movement. What might be the cause, and what treatment should be given?*

M.D., Maryland.

Answer:—Etiological possibilities include migraine, hypertension, and psychogenic or emotional factors that produce stress. Allergy to food or something in the environment may be present. The condition may be due to nasal congestion normally occurring during coitus superimposed on nasal or sinus allergy or pathology. These effects may be accentuated by excessive smoking associated with drinking. Toxic states or endocrine or biochemical factors may be at the root of the trouble. Other causes may be skull tumor, pheochromocytoma, and aneurysm, among others. For migraine, treatment consists of a combination of ergotamine tartrate and caffeine. For psychogenic or emotional factors, analgesics and psychotherapy are used. In allergy, desensitization or avoidance is the key. For nasal congestion, vasoconstrictor nose drops and analgesics are effective. The other conditions obviously require special investigation and treatment.

ORAL SURGERY DURING ANTICOAGULANT THERAPY

To the Editor:—*It is becoming increasingly more common to encounter patients who are on long-term anticoagulant therapy and who require extraction of teeth or other oral surgery. One approach to this problem has been to withdraw the anticoagulant about 48 to 72 hours preoperatively, perform the extractions, and then reinstitute anticoagulant administration 24 or more hours later. Some insist on prothrombin time determinations for confirmation; others do not. Vitamin K_1 is recommended by some and not by others. Still others feel that the dangers of thrombosis far outweigh the problem of postextraction hemorrhage and prefer that anticoagulant therapy not be discontinued. This latter group is of the opinion that local bleeding from an extraction wound can be managed by local measures. Please give comments and suggestions.*

M.D., New York.

Answer.—Patients on anticoagulant therapy will show a strong tendency toward prolonged hemorrhage. This risk must always be considered when oral surgical procedures are contemplated. It is little appreciated that blood loss during some oral surgical procedures is comparable with that occurring in major surgical procedures. Experience at the New York Veterans Administration Hospital indicates that anticoagulant drugs be withheld before dental operations (Ziffer and others, *New England J. Med.* 256:351, 1957). Prompt resumption of therapy when hemostasis has been obtained will result in minimal interruption of anticoagulation therapy. The patient's oral surgeon and physician, or cardiologist, should determine after consultation the treatment plan for the individual patient relative to the cessation of anticoagulant therapy and/or vitamin K administration. The oral surgeon should not assume the responsibility for the discontinuance of anticoagulation therapy.

CONTRECOUP BRAIN DAMAGE

To the Editor:—*A 75-year-old man was struck over the forehead in an accident. He was unconscious for a short length of time. X-rays revealed no fractures. After the accident he complained of unsteadiness and severe frontal headaches; these have persisted. He has also complained of profuse discharge from his nose, mouth, and eyes only when eating. This phenomenon has persisted. Audiometric tests revealed bilateral severe nerve deafness. Findings in vestibular function studies (caloric stimulation) were normal. Neurological examination findings were entirely negative. The nasal discharge, which was clear, was tested for presence of cerebrospinal fluid, with negative results. Examination immediately after the patient had taken a few bites of food revealed a profuse clear discharge from the middle and superior turbinal areas in each side of the nose. The mucosa appeared to be normal. A profuse discharge of clear saliva could be seen issuing from each Stensen's and Wharten's ducts. In addition, a profuse epiphora concurred. A search of the literature has been unrevealing for the pathoanatomic basis of this phenomenon. Please supply information on this.*

Joseph Freeman, M.D., Miami, Fla.

Answer.—It is likely that the finding of severe bilateral nerve deafness is the key to the explanation of the phenomena described. It is well known that trauma to the forehead can, by contrecoup, damage petrous pyramid structures bilaterally without a demonstrable fracture of the base of the skull. The equivalent of a contusion is produced and later organized as a scar, with or without bony thickening in the damaged area. The bilateral nerve deafness is probably related to trauma in and beyond the tractus spiralis foraminosus at the fundus of the internal auditory meatus. Just superior to the falciform crest of the internal auditory meatus is the facial nerve, and at the nearby genu is its geniculate ganglion. The nervus intermedius carrying efferent parasympathetic secretory fibers to the submaxillary ganglion and to the sphenopalatine ganglion, and afferents through geniculate ganglion fibers to the nucleus of the tractus solitarius, would be just as vulnerable as auditory fibers. So would the preganglionic parasympathetic fibers of the small superficial petrosal nerve, which tunnel from the middle ear to the anterosuperior face of the petrous pyramid very close to the geniculate ganglion and facial hiatus on the way to the otic ganglion. The latter structure supplies postganglionic parasympathetic secretory fibers to the parotid gland. Damage in the areas described could produce all of the symptoms noted including the epiphora, which is induced by orbital branches of the sphenopalatine ganglion.

ALKALI THERAPY WITH PAS

To THE EDITOR:—*In the treatment of tuberculosis, when PAS is being given in the usual dosage of 12 Gm. per day, is one justified in using an alkali, such as magnesium trisilicate and/or aluminum hydroxide, to allay stomach distress? Does the alkali interfere in any way with the potency of PAS?*

E. K. Disney, M.D., Dawson Springs, Ky.

ANSWER.—There is no objection to giving a compound such as magnesium trisilicate–aluminum hydroxide to a patient who is on PAS regimen; it would be better to give it at a different time, however. The alkali does not interfere with the potency of PAS. To patients who are very distressed by one form of PAS, the calcium salt may prove less irritating.

LIVER FUNCTION TESTS AND CHOLECYSTOGRAPHY

To THE EDITOR:—*Please give information on the correlation between liver function tests, specifically, sulfobromophthalein excretion, and oral cholecystography. A patient, not jaundiced, has normal findings on liver functions tests; however, cirrhosis is strongly suspected. This patient shows no shadow after being given gallbladder dye on repeated occasions. Also, in other patients with mildly impaired liver function, according to liver function tests sometimes no dye is found in the gallbladder. Have any studies been done on correlating these two methods of examination?*

R. F. Hartwich, M.D., Winona, Minn.

ANSWER.—Several studies have been made and published on this point. It has been shown that, when liver function is sufficiently impaired, even in the absence of jaundice, the gallbladder dye is not properly extracted from the blood. As a result, the gallbladder is visualized poorly or, perhaps, not at all. It is somewhat difficult to accurately predict the degree of liver damage necessary to influence gallbladder visualization. Since sulfobromophthalein is extracted from the serum in a somewhat similar manner as gallbladder dye, the results of this test correlate better with those of gallbladder visualization than any other. Sulfobromophthalein retention of over 20% is usually associated with a dim or absent gallbladder shadow. On the other hand, in the presence of active inflammation in the liver, as indicated by positive findings on flocculation tests, one may have a dim shadow even though the sulfobromophthalein retention is only 7 or 8% at the end of 45 minutes.

VITAMIN C

To THE EDITOR:—*What is the difference between vitamin C from natural sources and the synthetic vitamin C—ascorbic acid—in regard to human metabolism in the so-called normal individual and in the patient with wound healing after operation?*

W. Forrester Maley, M.D., Chicago.

ANSWER.—Vitamin C is a specific chemical entity, and, therefore, the body is unable to differentiate between sources of this chemical (ascorbic acid). Whether the body obtains its vitamin C from synthetic ascorbic acid or from orange juice, the manner in which this substance is utilized by the body is exactly the same. Vitamin C is used by some physicians in quite massive doses postoperatively, but apparently the rationale for such administration is open to question. The following quotation, taken from the book "Modern Nutrition in Health and Disease" by Wohl and Goodhart (Philadelphia, Lea & Febiger, 1955), sums up quite accurately the current concept of the role of vitamin C in patients after operation.

> Large doses of ascorbic acid have been used by many surgeons in their post-operative patients in order to facilitate the healing of surgical wounds. This idea was based on the observations that stress situations like surgical operations and severe burns about the body lowered the serum ascorbic acid level and that ascorbic acid concentrated in the connective tissues about healing wounds. It was based also on the well-known clinical experience that scurvy impairs wound healing. However, more recent data indicate that ascorbic acid metabolism is in a state of flux in post-operative patients, and that the serum levels do not correlate well with platelet, white blood cell (buffy coat) levels.

	Ascorbic Acid (Mg. %), Av.		
	Buffy Coat	Whole Blood	Plasma
20 normal persons	15.2	0.73	0.69
200 surgical patients	14.5	0.48	0.36

> Levels in the anterior rectus fascia below 1.5 mg. per cent indicate significant deficiency and are usually correlated with plasma levels of less than 0.2 mg. per cent. Plasma levels above 0.2 mg. per cent in such surgical patients usually indicates adequate tissue saturation. Only when the buffy coat ascorbic acid concentration falls to very low levels is there danger of wound disruption, and examples of this difficulty

are extremely rare. From the experimental evidence available at present, it would appear that the low plasma ascorbic acid level in patients just subject to a stressful procedure like major surgery is due to redistribution of ascorbic acid within the body rather than to an actual deficiency of the vitamin. A similar phenomenon occurs in iron and vitamin B-complex metabolism.

COMPLICATIONS OF ROUTINE LAPAROTOMIES

To the Editor:—*How frequently is spontaneous pneumothorax unexpectedly encountered during routine laparotomies (e. g., appendectomy)? How frequently does this condition complicate therapeutic pneumoperitoneum? How frequently does it complicate therapeutic or spontaneous pneumothorax?*

Joseph W. Kimbrough, M.D.,
Albuquerque, N. Mex.

Answer.—None of several general surgeons who have large surgical practices can remember encountering pneumothorax as a complication of routine laparotomies unless there has been some surgical injury to the diaphragm. If such a complication should occur, it may be due to the rupture of a small bleb on the lung rather than to any air from the peritoneal cavity entering the pleural cavity. In a long experience with artificial pneumothorax and pneumoperitoneum, this consultant can recall only one case in which there was diaphragmatic hernia. It is not felt that diaphragmatic hernia can in any way be related to artificial pneumothorax or pneumoperitoneum. If a diaphragmatic hernia with a peritoneal sac is already present, one would expect air from a pneumoperitoneum to enter this sac, and, if a traumatic diaphragmatic hernia were present without a sac, one would expect the air from the peritoneal cavity to enter the pleural cavity. In one instance the pneumoperitoneum was done as a therapeutic procedure in an attempt to locate the diaphragm. When the x-ray was taken with the patient in the upright position, there was no air in the abdomen but there was a well-defined pneumothorax. At operation, a large rent in the diaphragm was found which made a direct connection between the peritoneal and pleural cavities.

UNUSUAL MEDICAL QUESTIONS

The Questions and Answers Department of The Journal *receives many letters describing unusual cases. Some of these are too detailed to be printed in the regular Questions and Answers section. From time to time those that represent apparently new or different clinical syndromes or other interesting medical data will be presented in this section of* The Journal.—Ed.

BRONCHOSCOPY AND BRONCHOGRAPHY

To the Editor:—*Please discuss the indications for and safety of bronchoscopy and bronchography. What determinations, such as that for vital capacity, should be done first to see if and how much the patient can tolerate these procedures—especially the aged? What is the accepted treatment for bronchiectasis? Is repeated bronchoscopy each time a patient has an upper respiratory infection good treatment? Is aerosol penicillin used for chronic lung infection? M.D., Iowa.*

Answer.—The ability of a patient to tolerate bronchoscopy is based on an evaluation of the respiratory reserve. It is contraindicated if the information to be gained is minimal in the light of the potential dangers of the procedure, such as in true bronchiolitis in an infant; acute generalized pneumonitis where the presence of a foreign body has already been ruled out by the history and findings; the presence of a severely narrowed laryngeal or tracheal airway, except when the bronchoscope is passed through the larynx to establish a comfortable airway while the tracheotomy is being performed; and an obviously inoperable carcinoma of the lung in which x-ray therapy also is contraindicated because of the patient's poor health (this state of affairs is exceedingly rare). Bronchoscopy is also contraindicated in patients with uncontrollable coughing, if the dyspnea is severe when the patient is at rest and lying down, when dyspnea is initiated from the effort of sitting up, and when the patient is able to speak only a few syllables with each breath. It is risky if the severe dyspnea is associated with cor pulmonale and with hemoconcentration. The procedure is dangerous if severe dyspnea is associated with cardiac decompensation or coronary insufficiency. The bronchoscopist must be particularly adept, working without trauma but with agility; he must be willing to stop before completion of examination in certain instances, such as dyspnea with pulmonary emphysema, where the back-pressure of breathing against the larynx is necessary for adequate filling of the alveoli with air, a need for the employment of a mechanical aeration-assist, as in bulbar poliomyelitis, and the presence of wheezing or other evidence of bronchospasm during procedure. He must also be willing to stop during or after previous procedures (bronchodilators may be used as necessary). Bronchoscopy is hazardous if the vital capacity is less than half of normal or if the maximum breathing capacity is less than twice the tidal air on quiet breathing. As a matter of fact, tracheotomy often is safer when the patient is "loaded" with secretions, but one should be prepared for mechanical respiratory assistance during and after the procedure if the patient needs carbon dioxide stimulation to breathe, i. e., if increased oxygenation causes irregular breathing, apnea, or other changes. The ability of the patient to tolerate bronchography is based on an evaluation of all factors mentioned under bronchoscopy, plus contraindications set by sensitivity to materials to be used for the bronchogram, such as iodine or iodide sensitivity discovered by the history and by testing and local reaction or burning when a small amount is introduced into the conjunctival sac or when a small amount is held in the mouth and by sulfonamide sensitivity on the basis of the history, when sulfonamide-iodized oil combinations are to be employed. Under such circumstances it is well to use another agent. Even more so than in bronchoscopy, bronchography is contraindicated if the potential dangers equal or exceed the probable benefits of this solely diagnostic procedure. The procedure should not be carried out if the pulmonary secretions are too abundant to allow adequate anesthesia and control of cough by anesthesia when the patient is unable to withhold coughing or to permit adequate filling of the tracheobronchial tree by the bronchographic agent or adequate filling without producing dyspnea. It is contraindicated if suppuration is bilateral and not amenable to surgery. Medical management of a marked suppurative bronchitis is essentially the same as for bronchiectasis. Therefore, the risk of bronchography is not entirely justified. Concerning special tests, the clinical evaluation of the patient is superior to any tests when the potential dangers of these procedures are considered. These include the evaluation of vital capacity, maximum breathing capacity, and other functions as previously mentioned.

Present therapy for bronchiectasis includes surgical as well as medical modalities. Surgical removal of the affected part of the lung is indicated where the disease involves something less than one-half of the 19 bronchopulmonary segments and particularly in the younger age group (under 35 or 40 years), since the life expectancy would be increased by segmental removal in two or three separate operations if the disease is extensive. This is especially so in saccular rather than in cylindrical bronchiectasis. Medical management needs to provide effective drainage of secretions by means of humidification of respiratory passages, postural drainage, a correctly used cough machine or intermittent positive-pressure breathing machines, expectorants, and mechanical aspiration, when necessary. Evaluation and treatment of allergic states is a factor in many patients who are resistant to other therapy (approximately 10% are in this group). Employment of bronchodilators is in order when wheezing or other evidence of bronchospasm is observed. Parenterally, epinephrine, aminophylline, and the like may be given, as well as aerosols, including levarterenol, amphetamine, or epinephrine. These are listed in the order of increasing side-effects on the cardiovascular system. In the category of relatively specific therapy, antibiotics administered by the parenteral route are more effective than those given by aerosol. Tetracyclines, alternating with the combination of oleandomycin and penicillin, seem particularly effective. Other antibiotics are administered on the basis of apparent improvement of the patient. It is frequently helpful to change the antibiotic after two weeks. Employment of autogenous vaccines helps only some patients. These seem most helpful in cases of staphylococcic infections. Repeated bronchoscopic aspiration in patients with chronic suppurative lung disease at the time of upper respiratory infection requires comment. The procedure is contraindicated in the acute phase, because it may result in a more severe infection or may bring about respiratory embarrassment due to edema. It is, however, frequently helpful in the subacute stages of the infection. Aerosol penicillin in chronic lung infection is still considered to be of some value, but less effectively so than the parenteral administration of antibiotics. Penicillin should be rotated with other antibiotics, e. g., every two weeks, in order to avoid the creation of resistant infections. Some clinical investigators claim this method to be relatively valueless, based in statistical consideration of large groups of patients with bronchiectasis.

ICY COLD NOSE

To the Editor:—*A 43-year-old woman, healthy in all respects, is going through the menopause normally but gets apparently intractable headaches. These are generalized and, sometimes, behind the eyes. With these headaches, which are quite frequent, her nose always gets cold as ice, which, of course, has to do with the sympathetic nerves. Her IQ is excellent, and she is mentally stable. Can "smog" or dust cause these headaches? What is suggested in the way of further investigation? Milton I. Steckler, M.D., Los Angeles.*

Answer.—There seems to be no evidence whatsoever of any allergic foundation for the patient's headaches or for the fact that her nose gets "cold as ice." A complete blood cell count should be done, with reference to eosinophilia, and, also, a nasal smear should be obtained if the nose is at all moist. If she has any nasal allergy, it should show itself on examination. In such cases, the nasal mucosa is usually pale and boggy. Polyps may or may not be present along with this. If a nasal smear showed 4% or more eosinophils, then the patient should be given complete skin tests and the condition evaluated from the allergic point of view. From the history given, it appears that these headaches are of the tension type and related to the menopause.

Answer.—A specific syndrome consisting of intractable, generalized headaches associated with an icy cold nose has not been reported in the literature. It might be postulated that since the cold nose is a vasomotor phenomenon the accompanying headaches are probably vascular in origin. Allergy to house dust may produce at least two types of headache. One is the nondescript, generalized headache which may correspond, in part, with the description in the question. This type of headache is believed to be due either to change in caliber of cerebral vessels or to actual edema of the brain. Many allergists believe that these occur most commonly in patients with food allergy, but they have also been reported as the result of allergy to inhalants. Smog, particularly in a patient with sensitive nasal mucosa, may act as a nonspecific irritant and produce a pseudosinus type of headache, usually associated with nasal stuffiness and watering of the eyes. This type of headache may also be produced by allergy to house dust. Assuming that the more conventional and more obvious causes of headache have been ruled out, further investigation to establish the cause of the headaches described should include allergy investigation. Simple allergy skin tests will quickly exclude the possibility of house dust as a cause. Whether further allergy investigation is necessary depends on the results of the screening tests and the history, particularly that of associated manifestations of allergy. Response to therapy and deliberate provocation of the headaches are often helpful as aids to diagnosis. Thus, the effects of vasoconstrictors and antihistamines on the symptoms should be investigated. Also, an attempt to reproduce the syndrome by vasodilators and suspected contacts may be indicated. It is patently impossible in this response to discuss in detail the difficult, and often controversial, differential diagnosis of headaches in connection with the syndrome described. For good reviews, the questioner is referred to Ogden (*Ann. Allergy* 14:384, 1956) and Graham (*DM*, p. 1, Jan., 1957).

HYPOFIBRINOGENEMIA

To the Editor:—*A 28-year-old woman delivered her fifth child in December, 1957. Prior to this pregnancy she had some menstrual irregularity with occasional intermenstrual bleeding. On April 16, 1958, she was admitted to the hospital with a complaint of leukorrhea, and a dilatation and curettage, cervical biopsy, and cauterization of the cervix were done. The tissue specimen showed chronic cervicitis, with erosion and proliferative endometrium, with mild congestion and edema. After these procedures were performed, bleeding occurred, and on May 7, 1958, she was readmitted for control of heavy bleeding. She was given transfusion, dilatation and curettage and cervical biopsy were done, and the cervix was cauterized. The tissue specimens showed acutely and chronically inflamed endometrium in the secretory phase and chronic cervicitis and endocervicitis. Cauterization was done several times as an office procedure in an attempt to stop the bleeding. Bleeding and clotting times were checked and found to be normal. In the operating room she was found to have active oozing from an area of cervicitis. This area was excised and closed with sutures. Dilatation and curettage were done, and an old laceration of the cervix was repaired. The tissue specimen showed glandular hyperplasia of the endometrium, with foci of acute inflammation, and chronic endocervicitis with erosion. At the end of this procedure there was no bleeding, but several hours later she began bleeding and now it became heavy, with large clots. Platelet count and prothrombin activity were normal. Her blood formed what appeared to be a good clot. She was given transfusion, phytonadione was administered intravenously, and the bleeding almost completely stopped. When she began bleeding heavily again, the fibrinogen level was checked and found to be 40 mg.%. She was given a fresh transfusion and two units of fibrinogen. The bleeding stopped, and, at the time of writing, the cervix appears to be healing well and she has had no bleeding for more than 10 days. After receiving the second unit of fibrinogen, the level was 350 mg.%. Total protein level was 7.8 Gm.%, albumin level 4.5 Gm.%, globulin level 3.3 Gm.%, and findings on cephalin-cholesterol flocculation test negative. Her thymol turbidity was 2.3 units. What is the probable cause of the low fibrinogen level? Is it related to abnormality of the uterus? What can be expected in the future and in the event of future pregnancy?* *M.D., New York.*

Answer.—The occurrence of hypofibrinogenemia in this patient is most unusual. This syndrome is generally associated with premature separation of the placenta, criminal abortion, a dead fetus, and, occasionally, severe toxemia of pregnancy. The fibrinogen level of 40 mg.% is in the range where clotting and prothrombin times should have demonstrated some abnormality. It is possible that there is a retained placenta which is elaborating either thromboplastic or fibrinolytic substances. However, in any event, this patient's condition should be evaluated from the standpoint of either a fibrinolytic disturbance or a circulating anticoagulant. It might be expected that this disturbance will return if the primary mechanism is either uterine or ovarian pathology. In this event, surgery may be necessary. Prior to any surgical procedure, adequate investigation for a coagulation disturbance of the type described above should be performed (see Stefanini and Dameshek, Hemorrhagic Diseases, New York, Grune & Stratton, Inc., 1955; Biggs and MacFarlane, Human Blood Coagulation, Springfield, Ill., Charles C Thomas, Publisher, 1957).

EMOTIONAL PROBLEMS FOLLOWING ORGANIC BRAIN DISEASE

To the Editor:—*The answer to the question on emotional problems following organic brain disease, in* The Journal, *Sept. 6, 1958, page 136, might lead the reader to draw some erroneous conclusions both about the nature of psychotherapy in general and about the particular problem in question. Thus, it is stated, "A person . . . can be helped by psychotherapy insofar as he is a reasonable individual." While it is true that the psychotherapist allies himself with the rational portion of the personality, the process of therapy is basically much less one of reasoning with the patient than of resolving, as much as possible, emotional conflicts that stand in the way of his using his reason. To dismiss a cerebral hemorrhage simply as a "lobotomy" ignores the interplay between the specific psychological structure (personality) which the patient brought to his illness and the psychological impact on this particular person of the catastrophe that has befallen him.*

Certainly, the psychotherapy of persons with organic brain damage has not been much explored, but some work has been done and published, for example, "Psychotherapy in the Treatment of Organic Brain Disorder Following Cerebral Vascular Accident," by Wesselius (Bull. Menninger Clin. 18:97, *1954). Though "any standard textbook on psychotherapy" might give the essential techniques, as suggested by the consultant, one would have to individualize the approach according to the patient's past history and present reactions to his illness.*

Aaron Paley, M.D.
1725 High St.
Denver 18.

The above comment was referred to the consultant who answered the original question, and his reply follows.—Ed.

To the Editor:—*The correspondent states that "the reader might draw some erroneous conclusions both about the nature of psychotherapy in general and about the particular problem in question." There are many schools of psychotherapeutic thought, but it is an accepted truism that the patient subject to psychotherapy must have an adequate amount of reasoning power. One does not carry out an extended course of constructive psychotherapy with a feeble-minded individual. As was previously stated, the individual must know his limitations and live within those limitations. Otherwise, he will create a great deal of emotional conflict because of his frustration. It is the battle to avoid frustration and guilt that causes emotional conflict.*

It is, of course, true that the personality resulting after a cerebral hemorrhage is dependent on the "psychological structure" which the patient had before his illness. No doubt such a cerebral hemorrhage would increase the patient's sense of frustration. If he were mature, with a well-integrated personality before the catastrophe, then he would be more apt to have an adequately integrated personality after the accident. Again, it has been observed that anything that removes the higher centers of the brain may remove emotional control and, perhaps, remove the sense of guilt. It is emphasized that the therapist must have an understanding of fundamental psychotherapeutic principles if he is to handle any emotional problem toward helping the patient adjust to a handicap.

POSTVACCINAL POLYNEURITIS

To the Editor:—*In the Aug. 30, 1958, issue of* The Journal, *page 2258, a question was asked concerning acute infectious polyneuritis after intradermal injection of Asian influenza vaccine. The reply indicated that, to the knowledge of the consultant, this had never occurred. A 26-year-old woman received 0.5 ml. of monovalent Asian influenza vaccine which was followed by mild local reaction for two days; one week later this was repeated and was followed, in addition to the local reaction, by a moderately severe myeloradiculitis, commencing 12 hours after the injection and gradually subsiding over the course of the next two weeks. The details of this were briefly mentioned in the C. D. C. Influenza Surveillance Report no. 20, Oct. 8, 1957. It is probable that the true incidence of mild neurological reactions to formalinized viral vaccines is unknown.*

Alex J. Steigman, M.D.
University of Louisville
Louisville 2, Ky.

The above comment was referred to the consultant who answered the original question, and his reply follows.—Ed.

To the Editor:—*Actually, this consultant rather hoped that the answer would bring forth such information, since it was stated that "a polyneuritis could possibly follow vaccination for Asian influenza." However, it should be pointed out that, in the case reported in the comment, the myeloradiculitis followed not a single injection but two injections given one week apart, indicating a sensitivity process. This type of reaction would be much more likely to occur after two injections.*

WASHINGTON NEWS

FROM THE WASHINGTON OFFICE OF THE AMERICAN MEDICAL ASSOCIATION

Medicare Contracts to Be Renegotiated by Mail . .

Democratic Party Advisors Back Hospitalization Under OASI . .

10 Diseases Show Decline in 1957 . .

MEDICARE WILL RENEGOTIATE CONTRACTS BY CORRESPONDENCE

The Office for Dependents' Medical Care (Medicare) has decided to renegotiate state contracts with physicians' representatives by mail next year instead of through conferences. Contracts will be for one year, as in the past.

Announcing the new procedure, Brig. Gen. Floyd L. Wergeland, in charge of Medicare for the services, sent the following letter to all contractors:

"The negotiation and renewal of all Medicare contracts for the calendar year 1958 has been completed. As you are aware, these negotiations involved 'a comprehensive examination and analysis of the maximum fees to be paid physicians participating in Medicare. The matter of administrative costs was not an issue during these negotiations as the adjustment of these costs for the initial contract period was made to the mutual satisfaction of the government and the contractor in every instance.

"In view of this background, we propose the extension of our present Medicare contracts for a period of 12 months, beyond their expiration dates in 1959. This is to be accomplished through the medium of correspondence. We will send Medicare contractors a proposed modification 45 to 60 days before the expiration of each of the respective contracts. Upon receipt of these proposed contract modifications, if acceptable to the contractors, it is requested that they be duly executed and returned to this office for execution by the contracting officer, after which copies will be returned to the contractors. However, if you do not agree with the proposed contract modification, please notify the contracting officer at once in order that any differences may be resolved."

DEMOCRATIC ADVISORY COUNCIL SUPPORTS FORAND LEGISLATION

The Democratic Advisory Council, which gives formal and informal advice to the party's Congressional leaders, favors enactment of a hospitalization program under social security (the Forand Bill), which was opposed by the American Medical Association at the last session of Congress.

The council included this recommendation among many others in a lengthy statement of comments and proposals drawn up at a meeting in Washington. The session was called to evaluate voter trends in the recent election and recommend a course for the predominantly Democratic 86th Congress that convenes Jan. 7.

However, there is no assurance that the party's leaders in Congress will accept all recommendations. When the council was formed two years ago, appointments were offered to 10 members of Congress, including House Speaker Rayburn and Senate Leader Johnson. Senator Johnson and Representative Rayburn declined to serve, as did all but two of the others.

On the Forand hospitalization proposal, the council declared:

"The following increased benefits and hospital care program should be adopted as the next several steps in insuring a secure life for our people:

"Increase social security tax payments by one-half of one per cent, split 50-50 by employers and employees, to finance hospital and nursing insurance for aged persons and other social security beneficiaries, including:

"1. Hospital care for 50 to 60 days per year.

"2. A limited amount of nursing service."

The council also proposed that the age limit of 50 years for disability payments under social security be eliminated, as "a disabled person is disabled whether he is 25, 40, or 50 years old." Other social security proposals would increase benefits 10% immediately and another 10% in the next three or four years, improve widow's benefits, increase the earnings ceiling on which OASI taxes are applied from the present $4,800 to $6,000 in the next two years and to $7,200 by 1962 or 1963.

An enlarged program of hospital construction (the Hill-Burton program) was proposed as well as loans to local comprehensive health insurance cooperatives. On the latter point the report comments: "This will provide the basis for the development and enactment of a comprehensive and integrated program for the insurance, protection, and improvement of the health of all of our people."

A "steady effort" to increase funds for medical research was recommended.

In a general statement, the council declared: "Thus, we are called upon not only to keep up with the many demands of growth and change, but also to overcome the backlog of unmet needs that the Republican administration has allowed to pile up. Our list of what is needed must perforce be an extensive one.

"Under our Constitution, we will have a Republican administration for two more years. The Congress must of necessity cooperate with this administration. The effort must be to lead the administration into doing the best of which it is capable.

"While we may expect the administration to continue to try to block some needed measures, the increased Democratic majorities in both Houses of Congress provide better means to overcome such opposition. While it will undoubtedly be impossible for the Congress to overcome administration objection to do all that should be done, it should now be possible to enact desirable legislation that the administration has previously defeated and to put through a larger portion of a clear and comprehensive Democratic program."

TEN DISEASES DOWN IN INCIDENCE FOR 1957

Final figures on the incidence of notifiable diseases in the U. S. for 1957, compiled by the National Office of Vital Statistics, show a substantial reduction compared with 1956 in 10 diseases. They are brucellosis, diphtheria, encephalitis, hepatitis, malaria, poliomyelitis, psittacosis, trichinosis, tuberculosis, and typhoid fever.

Substantial increases were reported for amebiasis, other types of meningitis, and streptococcic infections. Diseases which showed little change in reported incidence were dysentery, rheumatic fever, meningococcic infections, and venereal diseases.

Cases of poliomyelitis totaled 5,485, which was lower than the number reported for any year since 1942, when the total was 4,167. The agency said the highest proportion of paralytic cases (79%) in any age group was in the one-year group.

MEDICAL SCHOOL CONSULTANTS HOLD FIRST MEETING

The surgeon general's consultant group on medical education held its first meeting early in December and assigned several staff studies looking to an eventual answer to the basic question of how many doctors are needed in the next decade. The group holds its second meeting in February. It set up a steering committee to work with the staff between regular meetings.

On the committee are Frank Bane, chairman of the 21-man consultant group; Dr. Edward L. Turner, American Medical Association; Dr. Ward Darley, Association of American Medical Colleges; Emory W. Morris, DDS, president of the W. K. Kellogg Foundation, and the Very Rev. Robert J. Slavin, president of Providence (R. I.) College.

Staff studies under way are construction costs of recently established medical schools and the financing of medical school operations.

MISCELLANY

For the first time since World War II the estimated number of veterans is showing a consistent downward trend, according to VA. On Sept. 30, there were about 22,723,000 veterans in civil life, the sixth straight month the veteran population has shown a decrease. Barring another war, the decline will continue unless there is an unforseen increase in the discharge rate of Korean war veterans, VA notes.

Veterans Administration and American Cancer Society are sponsoring a program for testing a method of mass screening of population groups for incipient lung cancer. About 8,500 residents of six VA domiciliary homes will be screened twice a year by use of the sputum cell analysis method, plus chest x-ray films. The VA said it will enable doctors to determine the extent of correlation between history of smoking, symptoms of bronchial and lung irritations and infections, and development of lung cancer in residents of the homes.

Social Security Administration is trying to reach about 400,000 persons who may be eligible for payments under the 1958 amendments to the social security law. An intensive effort is being made by the Bureau of Old Age and Survivors Insurance and its 584 district offices to reach newly eligible persons and inform them that claims must be filed before benefits can start. SSA said in many cases it cannot identify or locate the eligibles.

Brig. Gen. Harold H. Twitchell is the new president of the Association of Military Surgeons. He is command surgeon of the U. S. Air Forces in Europe, located at Wiesbaden, Germany.

Three hundred representatives of colleges and universities in the central Atlantic area and Puerto Rico and the Virgin Islands attended a Washington, D. C., conference on the new national defense education act. Discussions dealt largely with loans to students, graduate fellowships, counseling and guidance institutes, and foreign language development. The law provides U. S. aid to educational institutions in all these areas.

Food and Drug Administration reports the seizure of 14 drugs and medical devices in October, 11 for alleged false and misleading claims. Three were vibrator devices offered as weight reducers. Shipments of a brand of cigarettes advertised as an aid in weight-reducing also were seized at Cleveland, Kansas City, Mo., Glendale, Calif., and Trenton, N. J.

Activities of the Army Medical Service reserve program were discussed at a two-day meeting of an advisory committee to the Army surgeon general. One of the reports was from retired Major Gen. Earle Standlee, staff director of the American Medical Association's Commission on National Emergency Medical Care.

A kit of guidance materials from the President's Committee on Scientists and Engineers will be sent to every junior college and similar institutions. The kit was given final approval by a special conference called to review its contents. The objective is to interest students at the precollege level in careers in science and engineering.

College and university enrollment for the current fiscal year has set another all-time record—3,258,556. The U. S. Office of Education says this is 6.2% more than last school year and the seventh consecutive year in which a new record has been set.

National Science Foundation announces a new program of summer fellowships to give secondary school teachers an opportunity for further graduate study and research in the sciences. About 750 fellowships will be offered. Information is available at the Teacher Program, American Association for the Advancement of Science, 1515 Massachusetts Ave., N. W., Washington 5, D. C. Completed applications must be turned in by Jan. 19. The foundation will pay tuition, travel, and dependency allowances and $75 per week.

NEUROSURGICAL CARE OF THE SEVERELY INJURED PATIENT

Guy L. Odom, M.D., Durham, N. C.

The frequency and gravity of injuries to the brain and spinal cord are such that they must be considered in the neurosurgical treatment of every seriously injured patient. It is necessary to recognize shock when it exists, for it must receive priority over everything else except when there is evidence of extradural hematoma. Shock is rarely caused by head injuries alone; its existence should immediately direct the examiner's attention to other parts of the body. The blood pressure, pulse rate, respiration rate, and temperature should be recorded every 15 minutes at first; at the same time the pupils should be observed as to size and reaction to light, and the state of consciousness must be determined. Extradural hematoma, if it occurs, requires immediate surgical intervention; if it is neglected, the results are either death or irremediable deficits. The immediate recognition of a spinal injury is of extreme importance in order to prevent further damage to the spinal cord. It is especially liable to be overlooked in the unconscious patient, and the transportation of such patients requires the greatest care. Surgery of compound depressed skull fractures can be delayed until the patient's vital signs are stable; and immediate laminectomy for spinal cord injuries is seldom required.

IT HAS BEEN estimated that injuries to the head occur in 72% of persons involved in automobile accidents and that 1 out of every 10 such injuries is dangerous or fatal.[1] These appalling figures indicate that the general practitioner and general surgeon must have adequate knowledge of handling the severely injured patient from a neurosurgical standpoint if the morbidity and mortality are to be reduced. The steady increase in the accident rate, despite the publicity of safety methods advocated by Shelden [2] and various organizations, indicates that the medical profession must continue to carry this gruesome burden.

It is impossible to adequately review all the problems encountered from a neurosurgical standpoint, and, therefore, I will confine my remarks to the decisions that must be made shortly after the patient is first seen and to treatment of acute emergencies.

Craniocerebral Injuries

It is frequently difficult to make a definite diagnosis or to completely evaluate a patient from a neurological standpoint immediately after an injury. In this complex situation one must, however, determine whether the patient is in shock, whether multiple injuries have occurred, whether there is evidence of increasing intracranial pressure, and whether there is evidence of spinal cord involvement.

The problems of shock and multiple injuries can be discussed together, because a severe head injury alone is seldom responsible for a state of shock.

From the Neurosurgical Division, Duke University Hospital and School of Medicine.

Read in the Panel Discussion on Management of the Severely Injured Patient before the General Scientific Meetings at the 107th Annual Meeting of the American Medical Association, San Francisco, June 23, 1958.

This should immediately direct the examiner's attention to the other organs of the body. Braunstein[1] reports that 44% of the patients with head injuries also have injuries to other parts of the body. The rupture of an abdominal organ or intrathoracic bleeding should always be considered in every patient with head injury who is in shock. The examination should also include a careful check of the extremities for long bone fractures to avoid fat emboli during movement. Multiple injuries of this type may be overlooked by the inexperienced examiner due to the fact that he becomes more concerned with the impairment in the patient's state of consciousness. The treatment of shock demands priority over everything else, unless it is obvious that the patient has an extradural hematoma. While the usual methods are being carried out to combat shock, the patient should not be moved for x-rays and scalp lacerations should not be sutured. The wound should be covered with sterile dressings and a tight elastic bandage applied. Most scalp bleeding can be controlled in this manner. In large arterial bleeders, the vessels may have to be clamped or ligated. If a fracture of an extremity is encountered, a temporary splint is applied.

Only after the patient's condition has stabilized can the necessary surgical procedures be carried out or the patient transported to another center.

The maintenance of an adequate airway is as essential as treating shock. The air passages may become obstructed by blood, mucus, and vomitus. This can be avoided by positioning the patient on his side with the head slightly lowered in order that dependent drainage may occur. At times suction is necessary, and, in patients with extensive faciomaxillary injuries, tracheotomy may be a lifesaving procedure. One should never hesitate to perform a tracheotomy in the unconscious patient who is having difficulty with respiration and is requiring frequent suction. Patients should not be transported unless someone is in constant attendance to prevent the aspiration of vomitus.

Observation and Treatment

After the first-aid procedures discussed above, if a closed head injury is present it may be necessary to observe the patient to determine whether the problem will be surgical or nonsurgical. The decision depends on whether the patient develops signs of increasing intracranial pressure.

The blood pressure, pulse rate, respiration rate, and temperature should be recorded every 15 minutes for one to two hours, then every 30 minutes, and finally every hour depending on the individual case. Elevation of the blood pressure, slowing of the pulse rate, rising temperature, and irregular respirations are indications of acute increased intracranial pressure.

Each time that the vital signs are recorded, the nurse should check the patient's state of consciousness. In the comatose patient, painful stimulation to the extremities should be used to determine whether there is less motor response on one side than the other.

The pupils are observed as to size and reaction to light each time the patient is checked. Unilateral dilation of the pupil followed by fixation is indicative of third nerve compression from herniation of the medial aspect of the temporal lobe over the edge of the tentorium. Bilateral constricted and fixed pupils and extensor rigidity of the extremities immediately after injury suggest mid-brain involvement and extremely poor prognosis.

If the patient is comatose, his position should be changed every two hours, an indwelling catheter should be used to avoid distention of the bladder and soiling the bed clothes, and he should be given fluids intravenously, 3,000 cc. daily (1,000 cc. of 5% glucose in saline solution and 2,000 cc. of 5% glucose in water), first for several days and then nasal feedings (electrolytes should be checked every two to three days). If the temperature becomes elevated, bed sheets and pajamas should be removed and an electric fan directed on the patient. Aspirin may be given by rectum, and, if necessary, cracked ice may be placed on a sheet over the patient. If patient is restless, 20-30 cc. of paraldehyde is given by rectum. Morphine should be avoided in all head injuries. Sodium phenobarbital, 60 mg. (1 grain), given intramuscularly every four to six hours is used to control convulsive seizures.

Extradural Hematoma

An extradural hematoma is one craniocerebral condition which requires immediate surgical intervention as soon as suspected if the patient's life is to be saved or marked residual neurological deficits prevented. Everyone who has had a transient episode of loss of consciousness should be observed for the first 12-24 hours with this possible diagnosis in mind. This is especially true if the accident occurs at night or if there has been an intake of alcohol. If the patient refuses hospitalization, a responsible relative or friend should be carefully instructed as to the situation and advised to rouse him every 30 minutes during the remainder of the night.

Extradural hemorrhages are caused by a linear fracture in the temporal region tearing the middle meningeal artery. The blow may have produced a short period of unconsciousness, but this is not so in every case. The hematoma with brain compression develops rather rapidly due to the arterial bleeder and sets up a chain of events which have already been discussed from the standpoint of increased intracranial pressure. The patient who has been clear mentally after an initial period of unconsciousness will become confused or semistuporous, his voluntary movements will become less pronounced on one side of the body, and his blood pressure will become elevated, with slowing of the pulse rate. It is at this stage that the diagnosis should be made and exploratory trephination performed. If the hematoma is not evacuated within a short period of time, coma will develop and the pupil on the involved side will become dilated and fixed to light from compression of the third nerve by a hippocampal herniation. If the patient has been permitted to reach this stage, immediate operation should be performed. There should be no delay for x-rays or even waiting for the patient's condition to stabilize if he is being treated for shock. The procedure is carried out with use of local anesthesia, and the usual methods can be continued to combat shock in the operating room. If a neurosurgeon is not available, the operation should be performed by a general surgeon. Valuable time will be lost in transporting the patient to another hospital, where he may be dead on arrival or irreversible damage to the brain stem may already have occurred. The later changes are due to the fact that the hippocampal herniation not only compresses the third nerve but also obstructs the spinal fluid pathway, which further increases the intracranial pressure. The herniation then enlarges with compression of the posterior cerebral artery, an infarction of the occipital lobe. Herniation of the opposite hippocampal gyrus will occur and both pupils become dilated and fixed to light. At this stage, brain stem involvement occurs with bilateral extensor rigidity of the extremities. The terminal phase of this sequence of events is hemorrhage into the brain stem. If a patient has developed bilateral dilated and fixed pupils, his prognosis is hopeless. The chances of survival even if the hematoma is evacuated and the herniation removed or tentorium split are nil.

It is always wiser to carry out exploratory trephination in the temporal region as soon as one suspects the possibility of an extradural hematoma by change in state of consciousness rather than to wait for evidence of a hippocampal herniation. Both temporal regions should be explored if the procedure is performed before localizing signs occur. If there are focal signs and a hematoma is not encountered on the suspected side, trephination should always be done on the opposite side. X-rays may be extremely helpful, if they have been obtained, by revealing a linear fracture crossing the middle meningeal groove or a shift of the pineal gland.

After evacuation of an extradural hematoma in the patient with third nerve palsy, the medial aspect of the base of the temporal lobe should be explored for a hippocampal herniation. If it has been present for a short period of time, it may be forced upward by injecting Ringer's solution into the spinal canal. If this fails, the herniation should be removed by suction or the medial edge of the tentorium should be split for a distance of 1.5 cm.

An acute subdural hematoma or extensive contusion and edema of the temporal lobe will produce a clinical picture which may be difficult to differentiate from that of an extradural hematoma. In the former, however, there is usually a history of a more severe injury and patient's state of consciousness is impaired from the time of the accident. Because of these possibilities, if an extradural hematoma is not encountered at the time of the exploratory trephination, the opening should be enlarged so that the subdural space and temporal lobe may be explored. At times, it is necessary to remove a portion of the contused temporal lobe because the softened edematous lobe may have herniated over the edge of the tentorium.

Compound linear and compound depressed fractures and penetrating wounds seldom require immediate surgical intervention, and operation can be delayed until the patient's vital signs are well stabilized and injuries to other parts of the body have been treated. Space does not permit a detailed description of the surgical procedures, but the following points must be stressed. The entire scalp should be clipped and shaved widely about the involved area; thorough cleansing and débridement of the scalp edges should be done; exposed linear fractures should be thoroughly inspected for hair and foreign material caught between edges of bone; and if foreign material is present the bone along both edges of the fracture line should be removed. In cases of compound depressed fractures, the bone fragments should be removed and cranioplasty performed at a later date. Depressed fractures over the large venous sinuses should not be elevated unless an exposure of the sinus on both sides of the fracture has been carried out in order that the bleeding from the sinus can be controlled if it has been torn. If the dura and cortex have been lacerated, a tight closure of the dura should always be obtained. In penetrating wounds, lumbar drainage of spinal fluid to decrease intracranial pressure is helpful in exploration of the missile tract.

Spinal Injuries

The immediate recognition of a spinal injury is of extreme importance in order to prevent further damage to the spinal cord. This is seldom a problem in the conscious patient, but it must be remembered that the unconscious patient may also have sustained an injury to the spine and spinal cord. In the comatose patient, the absence of deep reflexes in the lower extremities, diaphragmatic respirations, and the failure to obtain any reflex movement to painful stimulation in the lower portion of the body and to do so over the arms or shoulders indicates involvement of the spinal cord.

In all suspected spinal injuries, proper transportation is essential. This also applies to conscious, nonparalyzed patients who may complain of neck or back pain or numbness or pain in an extremity or extremities. More damage may be done to the cord by jackknifing the back or flexing the neck during transportation by an enthusiastic sympathizer than at the time of the original injury. The patient should not be lifted unless sufficient assistance is available to prevent flexion of the spine, and he should be placed on a firm, flat stretcher. Patients with injuries to the cervical spine do better on the back with sandbags or some other object along the side of the head and neck because of the diaphragmatic respirations. Those with lumbar or thoracic fractures may be placed on the abdomen.

As in head injuries, treatment of shock and maintenance of adequate airway assume prime importance. Intranasally administered oxygen should be used in all patients with cervical cord injuries, and, at times, immediate tracheotomy should be done if the injury is at the mid-cervical level. If the vital signs are stable, adequate x-rays should be obtained as soon as possible. In patients in whom cervical injury is suspected, the shoulders must be pulled down to obtain adequate exposure of the seventh cervical vertebra and views should also be taken of the odontoid process. The patient remains on the x-ray table while the films are being developed, and at this time he may be rolled on his side and a manometric examination carried out to determine whether there is a block in the subarachnoid space. As soon as the films are developed, a decision can be made as to the next step of relieving cord compression and reducing a fracture dislocation.

Cervical fracture dislocations can be reduced in a matter of hours by means of Crutchfield tongs with 20 to 40 lb. of traction. One should begin with 20 lb. and obtain periodic portable films to follow the reduction. The weights are gradually increased, depending on the case. After reduction, the patient is left in traction but the weights reduced to 10 to 15 lb.

In patients with cervical injuries who require immediate surgery of some other part of the body, tongs and traction should be applied before proceeding with the operation.

An indwelling catheter should be inserted shortly after admission and, if abdominal distention occurs, Miller-Abbott and rectal tubes should be used.

Laminectomy is seldom performed as an emergency procedure in closed injuries to the spinal cord and, in fact, may be an added unnecessary risk, especially in patients with injuries to the cervical cord. If a complete reduction cannot be accomplished by traction, an open reduction can be done a week or so later.

Fractures of the lumbar spine with involvement of the cauda equina present a different problem than fracture dislocations in the cervical and thoracic regions. If there are not other serious injuries, surgical decompression of the roots of the cauda equina will give a better prognosis.

In penetrating and gunshot wounds, operation is performed as soon as the patient's general condition will permit. The depressed bone fragments and foreign material are removed and the lacerated dura closed.

Summary

In care of the severely injured patient from a neurosurgical standpoint, one must determine first whether the patient is in shock, second, whether there are multiple injuries, third, whether there are signs of increasing intracranial pressure, and, fourth, whether there is evidence of spinal cord involvement. Shock must receive priority in treatment, except when there is evidence of an extradural hematoma. Maintenance of an adequate airway is important. Surgery of compound depressed fracture can be delayed until patient's vital signs are stable.

Attention must be paid to signs of spinal cord involvement in the unconscious patient. Further, the patient must be protected from additional cord damage during transportation. Spinal cord injuries seldom require immediate laminectomy.

CARE OF THE PATIENT WITH MULTIPLE INJURIES

Otto E. Aufranc, M.D., Boston

There can be no rigid rules for the management of all extensively injured patients. The early recognition and management of important unsuspected lesions, however, will help to prevent additional superimposed trauma which, in itself, may make the difference between life and death or between mere survival and independence. The most important immediate problems consist of recognizing or establishing an adequate airway, preventing further hemorrhage, replacing blood, and avoiding damage by injudicious movement of the patient or his injuries.

Immediate Measures

We all know that the movement of the patient from the site of injury can itself be the actual cause of death. Transportation should be undertaken by trained persons, and those who do not know what to do should not do anything except try to get additional help. Transportation with the simplest type of side-splinting is probably the best. The control of hemorrhage by direct pressure compression bandages as opposed to a tourniquet is probably also best. Movement of the patient from the site of injury to the hospital should not be done with great speed but with great care and gentleness. Sudden starts and stops, bouncing over rough roads, and swerving around corners cannot do the injured patient any good.

Establishment of Extent of Injury.—The physician who first examines the patient should do a complete, rapid physical examination by a system, being sure in his own mind what he should look for. As with any physical examination, looking for the normal immediately reveals the abnormal. We should use all the senses we have been taught to use. We should look, we should feel, we should smell (alcohol, vomitus, feces, and urine acetone), we should listen, but, most of all, we should think.

A simple recording of the clinical findings is essential, since the clinical course of the patient and progressive changes of signs and symptoms are often the actual key to correct diagnosis. Recording of important negative findings which later change to positive makes a different prognosis. This is particularly true of intra-abdominal, head, and chest injuries.

Evidences of certain traumas are obvious to anyone. However, a more serious injury may be undetectable at the initial examination. Visceral injuries of this nature frequently manifest themselves hours after the initial trauma. They must be specifically suspected and specifically looked for in order for the physician to be ahead of their devastating possibilities if they are found out too late.

In dealing with an extensively injured patient, the most immediate problems consist of preventing asphyxia, stopping hemorrhage, replacing blood, and avoiding damage during transportation. The physician who first examines the patient must be systematic, and after the immediately evident problems have been dealt with the less obvious injuries must be considered. Fractures of extremities are overlooked in some cases; in others they hinder the physical examination and may divert the examiner's attention from serious spinal, intra-abdominal, or intrathoracic injuries. Sucking wounds of the chest, severe uncontrolled hemorrhage, and penetrating wounds of the abdomen require emergency operation. When combined abdominal and thoracic injuries are encountered, the thoracic portion is undertaken first. In many situations prompt action is more important than specialized knowledge, and such measures as clearing the airways by aspiration or tracheotomy, closure of open chest wounds, transfusion, splinting, or amputation may be lifesaving.

The orthopedist is taught to suspect a combination of injuries in certain types of trauma. For example, fractured patella and dislocation of the hip are often combined. The os calcis fracture is also often associated with a central dislocation of the hip or a fracture of the spine or of the base of the skull or both. A crushed pelvis is frequently combined with a rupture of the posterior urethra. Chest injuries are often associated with a ruptured spleen or a diaphragmatic hernia, and penetrating chest wounds may and often do involve abdominal viscera. These combinations must be thought of in order not to be overlooked.

Asphyxia, severe hemorrhage, and shock are common features in multiple injury cases, and immediate recognition and treatment are necessary. First, an open airway is essential to life and must be provided for at once. Simple manipulation of the tongue, mandible, or both or the change of position of the head and neck may be all that is necessary in the semiconscious or unconscious patient. Suction applied to or wiping out the upper airways

---

From the Department of Orthopedic Surgery, Harvard Medical School.
Read before the General Scientific Meeting at the 107th Annual Meeting of the American Medical Association, San Francisco, June 23, 1958.

may be sufficient to remove blood or mucus to establish a normal rate of respiratory exchange. At times, however, a tracheotomy must be resorted to as a lifesaving measure. It should be resorted to more frequently than the "wait and see" method when the patient seems to be in extreme condition. In those patients who do not have a cough reflex for clearing the upper passage, suction and administration of oxygen through a tracheotomy tube can be maintained with ease and infinitely more efficiently than by any other method.

Control of Hemorrhage.—Gross hemorrhage is the most common and often the simplest of all the conditions to alleviate. The application of local pressure, the use of the hemostat, and ties on grossly bleeding, pulsating vessels will control bleeding. However, pressure dressings carefully packed by the experienced surgeon are probably as efficient as any method of controlling hemorrhage. Such things as previously applied tourniquets and dressings should be removed so that the hemorrhage may be estimated and one can be more definitely sure that further loss of blood may not be a part of the maintenance of a shocked state. Concealed hemorrhage in the thorax, abdomen, or retroperitoneal space may cause death. In the severely injured patient, blood replacement therapy should be initiated at once and, while replacement of blood is being brought about, a more careful evaluation of the patient is easier and more surely apt to save his life—continued massive hemorrhage is not compatible with life for even a short duration of time.

The arrest of hemorrhage in the extremities probably deserves a specific note. Simple adequate elevation of the arm or leg often stops hemorrhage. In most cases arrest of hemorrhage might be better brought about by the use of a hemostat. However, the blind application of the hemostat to bleeding vessels is to be condemned, as the clamping in a sea of blood may well destroy arterial tissue that might not otherwise be destroyed and may preclude an otherwise reparable suture of a major vessel. Major nerve trunks usually accompany major arteries, and a previously damaged nerve may be permanently injured by blind clamping.

The use of a tourniquet when applied by an expert, of course, is invaluable. It requires precise application to arrest all arterial flow. Often tourniquets only obstruct the venous return and thus increase the bleeding. If the tourniquet has been applied and is adequate, it should be left in place until someone can adequately inspect the wound and determine the cause of the hemorrhage. At such a time when blood replacement is possible, several hours can elapse, if the extremity is kept cool, without really damaging the limb.

The amount of blood lost by a patient with a fractured thigh, for instance, may be excessive even though that might be the only injury. The blood loss may be excessive in relation to the loss from circulation. An increase in thigh measurement of 2 in. or more usually means that perhaps as much as 1,500 to 2,000 cc. of blood has been lost in that thigh. With musculoskeletal injuries o both legs and arms, for instance, as much as 3,000 to 4,000 cc. of blood might be lost to the circulation by the swelling and the hemorrhage around the fracture sites themselves.

As soon as an adequate airway has been established, hemorrhage arrested, and blood replacement started, the obvious fractures should b splinted to prevent further trauma and shock. Majo fractures, strangely enough, are commonly overlooked. Minor fractures and, frequently, dislocations of the major joints may go undetected. Fractures must be reduced and splinted not only to insure union and function but, mainly, to combat shock.

Shock.—Shock of some degree is associated with all multiple injuries. The main cause of shock is often loss of circulating blood volume. Replacement therapy, to be effective, must be prompt. It is best done by the use of whole blood, which increases circulating fluid volume, as well as the number of erythrocytes, to handle oxygen and carbon dioxide requirements in the tissues. Saline solution is invaluable as a temporary agent for raising the blood pressure only while awaiting plasma or whole blood. It should be only used in emergencies, because it leaves the circulation rapidly and takes plasma protein with it. Dextrose in water, as well as saline solution, is essential in treatment of shock.

Since it is important to allow prompt treatment of wounds which have caused the shock, it is essential to replace the missing blood before undertaking the management of the injury. This can usually be undertaken soon after the rise of blood pressure to over 80 mm. Hg with a fall of pulse rate and return of color and warmth to the skin. Blood replacement must be continued throughout the early surgical treatment as necessary. Trendelenburg position of the patient, elevation of the extremities, and the administration of oxygen are all useful adjuncts to the treatment.

Physical Examination.—Some of the diagnostic problems clarify themselves through the usual methods we have been taught, such as taking a good history and doing a careful physical examination. The knowledge of the mechanism of injury may give a real clue to concealed pathological changes. The obvious injuries must not divert the concentration of the careful examiner and thus allow him to overlook other things, such as serious spinal, intra-abdominal, or intrathoracic injuries. The fracture of an extremity and its obvious deformity often detracts from a careful physical examination. For instance, fractures of the extremity or bleeding from head lacerations often attracts attention to such a degree that frequently these are investigated too thoroughly by x-ray and other studies while the obvious but infinitely more important areas and serious internal injuries may go undetected. One must always guard against too many x-ray examinations when the general physical examination would have done just as well, if not better.

The physical examination must be quick, gentle, and without undue exposure. X-rays should be taken only when necessary and with minimum movement of the patient. It is possible that movement from a stretcher or table to an x-ray table will produce a profound circulatory collapse. It is much better to treat the patient as he is without x-rays rather than be forced to delay urgent therapy because of more shock induced by the performance of an x-ray examination. Roentgenograms for essential diagnosis and correct management can be more safely taken in the emergency room without moving the patient.

Initial Management of Specific Types of Injury

Immediate first-aid measures include control of asphyxia and hemorrhage, management of shock, and temporary splinting of fractures. The surgeon must then focus his attention on specific injuries and treat them with priority in regard to immediate and ultimate management. A decision must be made as to what operative procedure should be undertaken and when. Obviously, sucking wounds of the chest, severe uncontrolled hemorrhage, and penetrating wounds of the abdomen require emergency operation. It is essential to remember that an appreciable number of patients will require formal surgical measures as an integral part of their resuscitation.

Chest injuries require priority in treatment of any serious disturbance of the cardiovascular physiology. Potential bronchial secretions, sucking wounds, pneumothorax, massive bleeding into the pleura, and cardiac tamponade all may lead to profound cardiorespiratory changes requiring immediate treatment. Thoracic injuries should be treated before other operative procedures are undertaken, and when combined abdominal-thoracic injuries are encountered, the thoracic portion is undertaken first.

Crushing injuries of the chest associated with multiple rib fractures and paradox movement of the portion of the thoracic cage present a particularly difficult problem because of the serious derangement of cardiorespiratory physiology. Tracheotomy is particularly valuable in such patients. Paravertebral block and local infiltration to control pain are effective in the maintenance of an adequate oxygen exchange.

Abdominal Injuries.—Blunt and penetrating types of trauma produce many lesions in the abdomen. A careful local examination of the abdomen must be undertaken, particularly in an unconscious patient. All penetrating wounds of the abdomen should be explored as soon as the general condition permits. Watchful waiting is dangerous. Blunt injuries are a little more difficult but are, nevertheless, serious. Ruptured spleen, bladder, lacerations of the liver and intestine, mesenteric hemorrhage, and other injuries to the pancreas all present diagnostic difficulties as a result of blows in the lower part of the chest or the abdominal wall. Lacerations of the kidneys and serious retroperitoneal hemorrhage may be associated with injuries to the spine.

Urologic Wounds.—Urine specimens must be obtained promptly in all seriously injured patients. The presence of blood indicates some injury; however, the degree of hematuria is not necessarily indicative of the degree of damage. Most urinary injuries can be treated conservatively, but rupture of the ureter, bladder, and urethra require early initial repair to prevent urine extravasation.

Neurological Damage.—Peripheral nerve function should be determined in the examination of any wound of the extremities. Simple tests for detection of nerve injuries in both the upper and lower extremities are well known, and detection is relatively easy. The discovery of a peripheral nerve lesion after manipulation is disturbing and requires immediate reinvestigation.

The state of consciousness frequently alters the extent and interpretation of the complete examination. It masks symptoms of serious injury and causes delay in the management of injuries otherwise easy to care for.

Orthopedic Problems.—Most traumatic lesions alone do not present a serious therapeutic problem, but, when encountered in combination with other things, they create a major surgical problem. An open reduction may be advisable when it is the only injury, but in multiple injuries it may be contraindicated. Débridement of open wounds, reduction and immobilization of fractures, early amputation of all devitalized parts, and other procedures all play a major part in the rehabilitation of the extensively injured patient. Early grafting or suturing of major blood vessels by those specialized in the field may be much more important as the immediate operation than fixing the fracture properly.

The prevention of infection should not be left out of an orthopedic surgeon's thoughts in managing his injured patient. The use of a broad-spectrum antibiotic and whole blood, débridement of devitalized tissue, and the use of prophylactic antitetanic serum and toxoid therapy are all essential.

Summary

In management of a patient with multiple injuries, efforts should be directed first toward relieving the causes of asphyxia and then to treatment of sucking chest wounds, maintenance of a free airway, arrest of hemorrhage and replacement of blood, splinting of fracture, and, finally, débridement of the contaminated wounds. During the time a patient is unconscious on a stretcher, no harm can come from carefully and simply splinting all extremities. Every physician who treats severely injured patients must be prepared to institute emergency lifesaving measures in any part of the body. He may not do as well as the specialist, but he can often do a tracheotomy and aspirate mucus and blood from the nose and throat, stop sucking chest wounds, give intravenous fluids and blood, and adequately splint badly mangled extremities.

The judicious performance of amputation of a badly mangled extremity can also make the difference between returning a patient soon after injury to an active useful life and condemning him to prolonged invalidism.

MANAGEMENT OF THE SEVERELY INJURED PATIENT—GENITOURINARY ASPECTS

John W. Schulte, M.D., San Francisco

A carefully considered, systematic, orderly approach is essential when one is dealing with possible injury to the genitourinary tract. Three fundamental steps are involved: history of injury, physical findings, and laboratory studies.

History of injury, physical findings, and laboratory studies are the three fundamental steps in the diagnosis of any urologic injury. To limit one's field of vision to just the possibility of a ruptured bladder would be shortsighted when the patient's immediate problem is anoxia and paradoxial breathing due to a crushed chest. The prognosis of anterior and posterior urethral trauma must be a guarded one. Dense strictures may result from these injuries, requiring periodic urethral dilatation for months or years. Immediate surgical treatment is indicated in rupture of the bladder after the patient has been suitably prepared. Shock must be treated first by whatever method is most appropriate. The common cause of ruptured kidney is a direct blow to the loin over the region of the 11th and 12th ribs. Follow-up observations should be made on patients who have sustained a ruptured kidney. A kidney may be injured sufficiently to cause its ultimate death, yet not sufficiently to warrant immediate operation. Such damage may be found only by repeat studies several months later.

Fundamental Steps in Diagnosis

History.—A careful history is all important. If the patient is unconscious, or unable to give an accurate account of his injury, a witness to the accident should be questioned.

Different varieties of trauma can be expected to cause specific lesions in the genitourinary tract. For example, a person working on a roof who falls astride a scaffold is most likely to rupture the bulb of the urethra. Someone who suffers a severe blow directly over a distended bladder is likely to suffer an intraperitoneal rupture of the bladder; a person who sustains a compression fracture of the pelvis is apt to have an extraperitoneal rupture. A blow over the angles of the 11th and 12th ribs is more likely to cause a ruptured kidney than ruptured urethra.

Physical Findings.—A thorough physical examination is mandatory and should include a rectal examination. To limit one's field of vision to just the possibility of a ruptured bladder would be shortsighted when the patient's immediate problem is anoxia and paradoxial breathing due to a crushed chest.

Rectal examination may demonstrate that the prostate gland lies in the middle of the pelvis rather than its normal position, which suggests complete rupture of the prostatomembranous urethra.

Laboratory Studies.—Laboratory studies are dictated by the patient's needs and should include blood cell count and hematocrit value determination, urinary studies with microscopic examination of the urinary sediment, and roentgenograms for skeletal and soft tissue injuries. Special roentgeno-

Read in the Panel Discussion on Management of the Severely Injured Patient before the General Scientific Meeting at the 107th Annual Meeting of the American Medical Association, San Francisco, June 23, 1958.

graphic examinations, such as the excretory urogram, retrograde cystogram, and urethrogram, are indispensable aids to diagnosis.

This discussion will be limited to diagnosis and treatment of the common types of genitourinary injuries—ruptures of the urethra, bladder, and kidney.

Ruptured Urethra

Ruptures of the urethra may be divided into two groups: (1) those occurring distal to the triangular ligament and (2) those proximal to it. The latter are further subdivided for purposes of treatment into complete and incomplete ruptures.

Anterior Urethral Injuries.—Ruptures distal to the triangular ligament are caused by direct, external trauma and usually occur at or near the bulb of urethra. A common type is the so-called straddle injury.

A blow to the perineum followed by bleeding from the urethral meatus, initial hematuria, or inability to void is the common history. If the rupture has been complete and the patient attempts to urinate, he may complain of pain and sudden increased swelling of the perineum and scrotum. These symptoms indicate urinary extravasation.

The most important positive physical finding associated with rupture of the anterior urethra is blood at the urethral meatus. Further examination reveals ecchymosis and edema of the scrotum and perineum. If urinary extravasation has occurred, the tissues are tense and distended from the urogenital perineum forward and edema may extend upward into the subcutaneous tissues of the anterior abdominal wall. Rectal examination demonstrates the prostate to be in normal position. If the patient has urinary extravasation, he may be acutely ill; rapid pulse and hypotension may be noted. In the absence of urinary extravasation, the patient, while complaining of pain, does not appear particularly ill.

A roentgenogram of the pelvis should be obtained to determine skeletal injury. This accomplished, the patient remains on the x-ray table and urologic studies are done. An urethrogram is obtained first. My practice is to mix K-Y lubricating jelly (containing boric acid, glycerol, chondrus, and tragacanth) with an equal part of a 25% methiodal (Skiodan) sodium solution for contrast medium; the mixture is gently instilled into the urethra with a bulb syringe, and anteroposterior and oblique roentgenograms are made. From these studies the site and degree of injury can be determined.

If the roentgenographic studies demonstrate an incomplete rupture, an attempt is made to pass an urethral catheter into the bladder. If this is successful, the catheter is left indwelling for three to five weeks.

If the films show a complete urethral rupture, or if a catheter cannot be inserted past the area of incomplete tear, immediate surgical treatment is indicated. The type of operation undertaken depends on the skill and training of the surgeon.

If there is any question in the surgeon's mind concerning his ability to deal with such a problem directly, the simplest and most expedient operation to perform is a suprapubic cystostomy. This procedure diverts the urine and obviates the possibility of urinary extravasation. Secondary repair of the urethral injury can be done later. If the surgeon feels capable of attempting primary repair, he should proceed at once.

If subcutaneous urinary extravasation has occurred at the time of or subsequent to the injury, adequate drainage of perineum and scrotum should be established. The urethra is a contaminated field, and organisms washed into the surrounding tissues by urine grow luxuriantly; a rapidly progressing phlegmonous type of infection may ensue which may soon be fatal.

Posterior Urethral Injuries.—Rupture of the prostatomembranous urethra results from a shearing type of force and is most often associated with severe trauma to the bony pelvis.

The history is usually of a direct blow to the pelvis, such as may occur in heavy industry or an automobile-pedestrian accident.

Positive urologic history consists of the patient being unable to void or having voided a small amount of grossly bloody urine. Abdominal pain is not specific because of the usually associated pelvic, skeletal injury.

In regard to physical findings, the presence of purplish discoloration above the symphysis pubis, with associated lower abdominal tenderness and spasm, suggests possible rupture of the posterior urethra. The most important physical finding is obtained from rectal examination. If there is complete division of the prostatomembranous urethra, the prostate will be felt to be high in the pelvis rather than in its normal position. Because of extravasation of blood and urine in incomplete rupture, the boundaries of the prostate may be indefinite.

Since such patients usually have multiple injuries and may be critically ill, they should be disturbed as little as possible; all ancillary diagnostic studies should be made at one time as soon as the patient's condition permits.

When the history and physical findings suggest rupture of the posterior urethra, an urethrogram made as previously described will demonstrate the site and extent of injury. An incomplete rupture will allow some of the contrast medium to enter the bladder and some to be extravasated. A complete rupture allows most of the contrast medium to extravasate around the bladder and prostate; the latter is seen to be elevated in the pelvis.

An alternative procedure is to pass an urethral catheter and perform retrograde cystography, with use of a 25% solution of methiodal. This is the usual method, since it may be difficult to determine by history and physical findings alone whether the bladder or posterior urethra is ruptured. When retrograde cystography is used, the catheter may be seen to lie outside the bladder in complete rupture of the urethra with perivesical extravasation of contrast medium. In incomplete rupture, the bladder may be seen to be elongated and compressed by perivesical collection of blood and urine with a leak at the site of injury.

In treatment, urethral continuity is reestablished and the pelvic retroperitoneum is drained. The technique used depends on the surgeon's judgment.

Prognosis.—The prognosis of anterior and posterior urethral trauma must be a guarded one. Dense strictures may result from these injuries, requiring periodic urethral dilatation for months or years. Loss of sexual potency, particularly with posterior urethral injuries, is common and may be permanent.

Ruptured Bladder

Rupture of the bladder is either intraperitoneal or extraperitoneal. The history of injury gives an important clue as to which form of rupture may be present.

Intraperitoneal Rupture.—A direct blow over the suprapubic area is most likely to cause an intraperitoneal rupture of the bladder. This is particularly true if the patient has a full bladder at the time of injury. Trauma is followed by severe suprapubic and lower abdominal pain and passage of bloody or smoky urine.

These patients may be in shock. The abdomen is tense, particularly in the lower quadrants, and board-like rigidity may be noted immediately after injury. Peristalsis is absent or hypoactive. Rectal examination may define a fluctuant area in the region of the cul-de-sac.

Laboratory findings reveal the urine to be usually grossly bloody or smoky. It occasionally may appear relatively clear, but microscopic hematuria is always present.

Retrograde cystography is diagnostic. Three films are made: a preliminary roentgenogram, a film with the bladder distended with a 25% solution of methiodal, and one after the bladder has been evacuated. It is important that the bladder be filled to capacity; a small tear may be sealed immediately by omentum and so not be visible otherwise on the roentgenogram.

The postevacuation roentgenogram is particularly important, because it shows contrast medium extravasated into the peritoneal cavity or pooled in the cul-de-sac.

Extraperitoneal Rupture.—The extraperitoneal rupture is most often associated with fractures of the pelvis and results from indirect trauma to the bladder.

The history is almost identical to that obtained in the intraperitoneal rupture, except for the type of trauma. A crushing type of pelvic injury is the usual story.

Physical findings are usually similar to those seen in patients with intraperitoneal rupture, with few exceptions. Among these are more localization of pain and spasm to the lower quadrants, a bluish discoloration of the suprapubic skin, and normal rectal findings.

Urinary studies also will give results similar to those found in patients with intraperitoneal rupture. Plain roentgenograms usually show deformities of the pelvic skeleton, varying from multiple fractures to separation of the symphysis pubis or sacroiliac joints.

Retrograde cystography done in the same manner as in intraperitoneal rupture shows perivesical extravasation of radiopaque fluid in the evacuation roentgenogram.

Treatment.—Immediate surgical treatment is indicated in both types of rupture of the bladder after the patient has been suitably prepared. Shock must be treated first by whatever method is most appropriate. Other injuries, if more pressing, are treated before urologic surgical repair is undertaken.

In both intraperitoneal and extraperitoneal ruptures of the bladder, abdominal exploration is mandatory. It is imperative that the peritoneal cavity be opened and the pelvic viscera, including small intestine and rectum, be examined; a force strong enough to cause rupture of the urinary bladder may also cause severe injury to adjacent organs. Injuries to other organs are treated first.

Treatment of intraperitoneal rupture of the bladder consists of mobilization of the rent in the peritoneum from the surface of the bladder, closure of the bladder mucosa and muscle, and reapproximation of the peritoneum. After this, urinary drainage is established suprapubically by means of cystostomy. Dependence on an indwelling urethral catheter alone is not recommended, since the lumen may become occluded, the bladder may become distended, and a leak may occur at the site of repair.

Treatment of extraperitoneal rupture of the bladder again consists first in exploration of the peritoneal cavity. If no associated lesions are present, the peritoneum is closed and the bladder is exposed extraperitoneally, the prevesical space being widely opened on either side. This permits drainage of the extravasated urine and blood. The bladder is then entered suprapubically, and a cystostomy drain is inserted. No attempt is made to identify the site of rupture unless it easily comes to view. Experience has shown that lacerations of the bladder will heal without suture if the bladder is put at rest by cystostomy drainage.

The prevesical space is drained for 10 days, at which time cystotomy tube and drains may be removed and the cystotomy allowed to close spontaneously or encouraged by means of urethral catheter drainage.

Ruptured Kidney

Because of its anatomic position and coverings, the kidney is not prone to injury. There are, however, predisposing causes for rupture of the kidney, the most common of which is hydronephrosis. The common cause of ruptured kidney is a direct blow to the loin over the region of the 11th and 12th ribs.

History and Findings.—The pertinent history is of a direct blow to the loin followed by pain in the affected side and the passage of grossly bloody urine, sometimes with blood clots. The pain is severe and may radiate anteriorly into the abdomen or groin.

The patient may appear acutely ill, pale, and perspiring and have rapid pulse and hypotension. Local physical findings demonstrate spasm of the flank musculature on the injured side with reflex guarding and spasm on the abdominal muscles. An area of ecchymosis may be noted over the loin.

On careful examination a mass in the flank may be felt. If a mass is found, its margins should be marked with ink on the patient's skin for future reference. If the urinary collecting system has been damaged, cutaneous edema may be seen over the area of the lumbar triangle from extravasation of urine.

The urinary specimen is almost always grossly bloody, and red blood cells are always seen microscopically.

A roentgenogram of the abdomen may show injury to the skeleton, including fractures of the ribs or transverse processes. Of diagnostic value is the absence of a psoas shadow on the affected side and the absence or haziness of renal outline.

The most useful diagnostic study used in proving ruptured kidney is the excretory urogram. Contrary to the beliefs of some, excellent studies of the upper and midurinary tracts may be obtained without the usual preliminaries of dehydration and catharsis.

Excretory urograms in the case of a presumably ruptured kidney should be done to obtain the following information: 1. The size, structure, and function of the unaffected kidney. A congenital, solitary kidney is not an uncommon anomaly, and congenital hypoplasia is not rare. It is obvious that a contemplated nephrectomy in the case of renal rupture must be predicated on the presence of a life-sustaining remaining kidney. 2. The degree of injury to the kidney itself. If there has been complete transection of the renal pedicle, contrast medium will not concentrate in the kidney. If the renal substance has been lacerated, intrarenal extravasation will be seen. 3. Injury to the collecting system. If the pelvis or ureter has been torn, extrarenal extravasation will be apparent.

Treatment.—Treatment is initially directed for the patient as a whole. He must be relieved of pain and given such supportive therapy as is necessary to overcome shock if present. Ninety per cent of patients with ruptured kidney require supportive therapy only. The type of operation in the remaining 10% depends on the type and severity of the injury. Surgical intervention should not be considered as long as the patient's general condition improves with supportive treatment. Ominous signs include continued shock in spite of supportive measures or increasing size of a mass in the flank, as demonstrated by repeated physical examination. Either indicates continuing hemorrhage.

If the patient continues to be in shock in spite of transfusion and ancillary treatment, immediate operation is indicated as a lifesaving measure. In my experience with such patients, either the kidney is completely shattered or its vascular pedicle is completely transected. Under these circumstances nephrectomy is usually the operation of choice, depending, of course, on the presence of a second, life-sustaining kidney.

Urinary extravasation demonstrated by excretory urography demands surgical drainage, but this is not urgent and can be done when the patient has recovered from the initial effects of injury. Drainage can easily be established by introducing a Penrose drain through Petit's triangle deep to Gerota's capsule.

Follow-up observations should be made on patients who have sustained a ruptured kidney. A kidney may be injured sufficiently to cause its ultimate death yet not sufficiently to warrant immediate operation. Such damage may be found only by repeat studies several months later.

ANILERIDINE HYDROCHLORIDE—ITS CLINICAL USE AS AN ANALGESIC AND SEDATIVE

PRELIMINARY REPORT

Robert C. Therien, M.D., Leroy W. Lee, M.D., Edward M. Malashock, M.D.
and
Neal B. Davis, M.D., Omaha

The clinical effects of anileridine hydrochloride have been observed after more than 2,500 administrations to more than 600 patients. It was used both as premedication for general anesthesia in surgery (in doses averaging 50 mg. orally or subcutaneously) and as a postoperative sedative and analgesic (in doses ranging from 25 to 75 mg.). Its effects resemble those of morphine and meperidine, but euphoria was uncommon, and no evidence of addiction was seen even in a patient who received 552 doses during the course of metastatic carcinoma of the colon. In patients who received the drug daily for various periods of time, there was no evidence of withdrawal symptoms when a series of administrations was interrupted. Nausea occurred in eight and emesis in six instances. Respiratory depression caused by excessive doses in a few patients was easily counteracted by levallorphan in doses of 1 mg. for every 25 mg. of anileridine hydrochloride. It was effective in the very old as well as the very young and showed promise of usefulness in a wide diversity of medical and surgical situations.

Anileridine hydrochloride is a substituted meperidine which is chemically known as ethyl-1-(4-aminophenethyl)-4-phenylisonipecotate dihydrochloride. The structure is shown in the figure. Experimental observations in animals and man have proved it to be a potent analgesic agent with high activity and relatively mild side-effects when given orally. In animals, the compound approaches the analgesic potency of morphine and is more potent than meperidine. It has a prompt onset of action (15 to 30 minutes) and a long duration of analgesia (five to six hours). The side-reactions, such as general depression, depression of respiration, and lowering of blood pressure, are considerably milder than those produced by morphine and somewhat milder than those of meperidine.

Synthesis of the compound was accomplished in 1956 by Weijlard and co-workers.[1] Pharmacological characteristics of anileridine were studied by Orahovats and associates,[2] who found aside from the characteristics already enumerated that the compound had an antitussive effect, an anticholinergic effect, and an antihistaminic effect. It did not produce constipation, as was seen with morphine. It was well tolerated by mice, rats, cats, and dogs in single and repeated administrations. Tolerance to the analgesic effect developed slower for anileridine than for either morphine or meperidine. Local tissue injection with 50 mg. of anileridine produced considerably less reaction than similar solutions of meperidine. The effects of anileridine were reversed by nalorphine (Nalline) hydrochloride.

Porter[3] described the absorption and metabolism of anileridine and suggested analytical methods for identifying anileridine in the tissues and body fluids. He stated that the metabolism and excretion of anileridine are similar to those of meperidine. The highest concentrations of anileridine were found in the lungs, kidneys, and brain. Major excretion was by way of the kidneys.

Observations on the effects of anileridine in man have been reported by Keats and co-workers,[4] Dripps and co-workers,[5] Wallenstein and Houde,[6] and Stage.[7]

Observations on Drug Usage and Effect

Our observations were begun shortly after the compound was synthesized in 1956 and proved to be suitable for administration to animals and man, and they have continued to this time. During this time we have given anileridine to over 600 patients. We have used various preparations of the drug and various methods of administration. These preparations have included tablet and elixir for oral administration, as well as solution for intramuscular, subcutaneous, and intravenous use. The drug was used for preoperative analgesia and sedation, as well as for postoperative analgesia. Observations for preoperative sedation were made personally by us. The postoperative analgesic effectiveness and durations were observed by special and regular duty nurses. These in turn were reported to the house staff physicians for evaluation. Patients with ad-

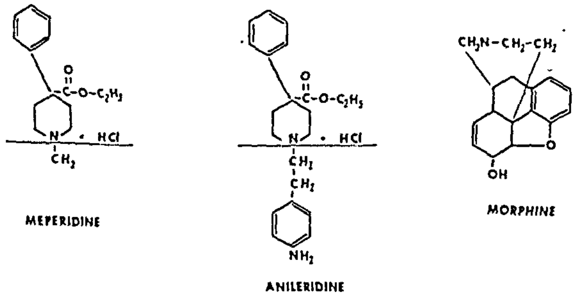
Read before the Section on Anesthesiology at the 107th Annual Meeting of the American Medical Association, San Francisco, June 25, 1958.

vanced painful carcinoma, as well as those with other painful clinical conditions, were observed for its analgesic effect.

In the entire study, anileridine was administered over 1,900 times. For preoperative medication it was given alone in 260 instances, with orally given vinbarbital (Delvinal) sodium, 100 mg., 302 times, and with atropine or scopolamine hydrobromide 70 times—making a total of 632 preoperative administrations. Doses varied from 25 to 100 mg., but the average subcutaneous and oral dose was 50 mg. For postoperative sedation and analgesia, anileridine was given 1,320 times. The dose ranged from 25 to 100 mg. The average doses were 50 to 75 mg.

In this series of 632 patients coming to surgery and receiving anileridine preoperatively, regional anesthetics were used in 562 and general anesthetics in 70 instances. The types of surgical procedures were as follows: cystoscopy (71), cystoscopy, ureteral catheterization, or manipulation (321), renal operations (24), ureteral operations (23), perineal prostatectomy (38), transurethral prostatectomy (61), suprapubic prostatectomy (4), suprapubic vesical operation (11), transurethral resection of bladder tumor (22), scrotal operation (70), bilateral adrenalectomy, retroperitoneal tumor (3), urethral or penile operation (23), presacral oxygen study (4), breast biopsy (2), and gynecologic surgery (59).

Inasmuch as several of these patients had two separate surgical procedures performed during the same hospitalization, it offered a novel way to observe the comparative effect of meperidine and anileridine preoperatively in the same patient. A group of 50 patients were given anileridine subcutaneously with orally given vinbarbital sodium on one occasion, and an equal dose of meperidine was substituted for anileridine on another. All medication in this series was given one hour preoperatively. Since the operative procedure in these patients was done with use of regional anesthesia, it was possible to observe them very accurately in the operating room and recovery room for a minimum of two hours. It was found that, in this series, 50 mg. of anileridine was as effective as 75 mg. of meperidine for comparable signs of analgesia and sedation.



Structural formulas for meperidine, anileridine, and morphine.

In patients receiving anileridine, the onset of analgesia appeared in 15 to 30 minutes and was profound at 60 minutes. The analgesic effect of anileridine appeared to last for one to seven hours, with an average of three to four hours. These observations were made with average dosages of 50 to 75 mg. No deaths or severe toxic reactions were seen incident to administration of anileridine. Overdoses in a very few patients were manifested by respiratory depression. The respiratory depression was easily counteracted by administration of levallorphan in a ratio of 25:1 for the unanesthetized patient. When intravenously given barbiturates were used with a general anesthetic, the antagonist dose was doubled, i. e., 12.5 mg. of anileridine was counteracted by 1.0 mg. of levallorphan.

Table 1.—*Case and Dosage Data in Patients Receiving Anileridine*

			Dosage Data		
Case, No.	Sex	Age, Yr.	No.	Size, Mg.	Interval, Days
1	F	74	66	50	20
2	F	21	35	50	9
3	M	70	31	25	21
4	F	22	28	50	8
5	M	74	23	50	15
6	M	59	27	75	30
7	M	33	47		8, 9*

* Patient received 23 doses in eight-day period and, on second admission two months later, 24 doses in nine-day period for second operative procedure.

Untoward effects observed were as follows: nausea (eight), emesis (six), vertigo (two), headache (two), sensation of choking (one), itching (one), and deep sedation (three). The latter effect occurred in patients receiving 75 mg., 100 mg., and 100 mg. respectively. No evidence of abdominal cramps or constipation was seen. Neither evidence of toxic psychotic effects nor severe circulatory depression was seen. Euphoria was uncommon.

Special Uses and Addiction

Special Uses.—Observations on special uses of anileridine were made as follows. In children, anileridine used both preoperatively and postoperatively appeared to be effective and well tolerated. The dosage given was one-half the standard accepted meperidine dosage for age and weight. The pain of ureteral colic, urinary and gallbladder spasm, and coronary thrombosis, peripheral vascular pain, and pain of metastatic carcinoma was relieved. In the geriatric age group, anileridine was effective preoperatively and postoperatively, as well as in other painful conditions. There were 170 patients over 80 years of age in this group. It did not produce the psychic disorientation so often seen with morphine when used in aged persons. The large percentage of geriatric-patient surgical procedures done is shown in the previous section. In the series were 12 severe diabetic patients and 5 with severe asthma. In both groups, the severe disease was not aggravated and the drug appeared to be well tolerated. Dripps and associates[5] have demonstrated the antihistaminic effect of anileridine in man. The severe tremor of Parkinsonism was noted to disappear in two patients after administration of anileridine.

Addiction.—We have found anileridine to produce no evidence of addiction. Our series includes several patients who received a considerable number of repeated doses with subsequent easy withdrawal of the drug. Table 1 shows dosage regimen of our patients receiving the drug hypodermically in multiple doses.

Orally, for metastatic disease, four patients received repeated doses as shown in table 2. In the patient in case 2 (table 2), medication was withheld 10 days during the middle of the series without evidence of withdrawal symptoms. A total of 105 patients received oral medication with anileridine. In all, this medication was well tolerated.

TABLE 2.—*Case and Dosage Data in Patients Receiving Anileridine for Metastatic Disease*

		Dosage Data		
Case, No.	Carcinoma of	No.	Size, Mg.	Interval, Days
1	Kidney	66	25-50	20
2	Bladder	100	25-50	30
3	Bladder	232	25-50	120
4	Colon	552	25-50	128

The oral route of medication for drugs is considered much less likely to cause addiction. The hypodermic route, for psychological reasons, is considered more likely to cause addiction in the person requiring continual narcotic medication. According to some psychiatrists,[8] the hypodermic route provides a symbolic-accentuation of the importance of the medicine. For this reason, anileridine with its high oral effectiveness can be considered a very useful addition to the group of orally effective drugs used for the relief of pain.

Summary

The clinical use of anileridine as a preoperative and postoperative analgesic and sedative was observed in a study of over 600 patients. This study showed anileridine to be a valuable addition to the present group of analgesic-sedative agents. It is effective given orally and parenterally, with a minimal amount of undesirable side-effects. Anileridine was found to be effective and well tolerated by children, as well as by patients of advanced age.

Further observations should be continued of the effects of anileridine in the management of patients with severely painful clinical conditions, such as ureteral colic, biliary colic, embolism, and coronary thrombosis. Its effects on patients with diabetes, asthma, and Parkinsonism should also be observed further.

Addendum

Since the completion of this study series, an additional 653 doses of anileridine have been administered, without any remarkable change from our previous study's statistics.

800 Doctor's Bldg. (Dr. Therien).

The anileridine used in this study was supplied as Leritine by Merck Sharp & Dohme Division of Merck & Co., Inc., Philadelphia.

ROENTGENOLOGIC EVIDENCE OF FETAL DEATH.—At roentgen examination of relatively mature fetuses before delivery, a zone of reduced density is usually discovered around the head of the fetus, produced by the subcutaneous layer of fat. If the fetus is dead, this transparent zone in certain cases is separated from the cranium by a layer of the same density as the other soft tissues of the fetus. This finding was described for the first time by Deuel in 1947 as a sign of intrauterine fetal death. Intrauterine fetal death can be determined in the majority of cases (more than 75 per cent) by means of a roentgenologic examination. Free gas is the most common and the most important sign of fetal death. In cases where the death of the fetus occurs when the fetus is almost at term, free gas and Deuel's halo sign are frequently noted, whereas when the fetus dies in an early stage of development, the most common roentgenologic sign of death is the maceration of the trunk. —O. F. Holm, Deuel's Halo Sign, *The American Journal of Roentgenology,* October, 1958.

THE PROBLEM OF CARDIAC ARREST

Kenneth C. McCarthy, M.D., Toledo, Ohio

Cardiac arrest is best defined as sudden cessation of cardiac function from the effects of anesthesia or surgical manipulation. The incidence of cardiac arrest has been recorded as anywhere from 1 per 696 to 1 per 24,000 operations. The natural tendency to evade responsibility by reporting deaths due to anesthesia as due to cardiac arrest must not be overlooked. The patient should be protected against noxious reflexes by proper and adequate premedication. Hypoventilation with its vicious offspring, hypoxia and hypercapnia, must be avoided. All exponents of the art of anesthesiology must be diligent and conscientious in preventing this tragedy.

The Chairman of the Section on Anesthesiology traditionally reviews the growth of the specialty from the date of Adam's historic thoracoplasty. Recent advances in research and technique may be viewed proudly, and certain innovations may be regarded as radical and therefore dangerous practices. However, a new day is certainly dawning; we are on the threshold of a new and glorious era in anesthesiology.

I am also in the happy position of knowing that this paper will have an assured if not attentive audience. This is too good a chance to pass up, and it gives an opportunity to discuss a problem that is assuming increasing importance in anesthesia and surgery. This subject is cardiac arrest.

This topic is attracting more and more interest. A superficial review of the literature shows six times as many papers published in the last 5 years as in the previous 50. Most of these authors believe that the incidence is increasing, but no one agrees as to what this incidence actually is. Some typical figures are as follows: Natof and Sadove[1] record the incidence of cardiac arrest as 1 per 696 operations, Lahey and Ruzicka[2] as 1 per 1,000, Hingson and co-workers[3] as 1 per 1,078, Briggs and associates[4] as 1 per 1,400, Jacoby and associates[5] as 1 per 1,588, Bergner[6] as 1 per 2,000, Johnson and Kirby[7] as 1 per 3,600, Bonica[8] as 1 per 4,150, Merritt and Osterhagen[9] as 1 per 8,600, and Blades[10] as 1 per 24,000.

This great disparity in figures must indicate that everyone does not mean the same thing by cardiac arrest. One of the greatest difficulties is to know what we are talking about. To describe this entity, Natof and Sadove[1] list 12 separate and different definitions. Of these definitions, that of Blades[10] is simple and logical: "sudden cessation of cardiac function from the effects of anesthesia or surgical manipulation." If this definition were followed, many cases would be eliminated that are now called cardiac arrest and the subject could be viewed in its true perspective. Some surgeons apply the term to every patient who dies in the operating room and who is not completely exsanguinated. Obviously, every death from any cause could be called cardiac arrest, for that is the final episode in every fatality. Actually, a careful analysis of operating room deaths shows that roughly half are due to surgical accidents, shock, or primary disease and should not be termed as due to cardiac arrest.[11]

These reviews also throw doubt on the widely held theory that there is an alarming increase in the incidence of this condition. For example, at Flower Hospital, Toledo, Ohio, the operative mortality has shown a steady reduction from 1.9% in the 1930's to 1.6% in the 1950's in spite of an increase in major pulmonary and cardiovascular surgery. Certainly there has been no increase in cardiac arrest or even operating room deaths. The apparent increase must be due to a greater awareness of the problem, so that more cases are recognized and reported. We must not overlook the natural tendency to evade responsibility by saying that a death due to anesthesia is due to cardiac arrest. The latter, for which no cause is known, is obviously an act of God for which human error cannot be held accountable.

Cardiac arrest has been defined as total circulatory failure for which no cause is apparent.[4] However, in every case there is a causative factor, and the reason that it is not apparent must be because we did not look for it or ignored it if present.

Causes

Hypoxia.—Oxygen lack has a twofold effect on the heart. Central nervous system depression causes respiratory and vasomotor failure with resulting cardiac hypoxia. There is also a direct effect on the myocardium, which, unlike skeletal muscle, cannot rest to restore oxygen debt. Even short periods of suboxygenation may produce cardiac standstill. Lactic acid, the normal product of muscular activity, increases with hypoxia. With a concentration of only 0.07% it will produce cardiac

Chairman's address, read before the Section on Anesthesiology at the 107th Annual Meeting of the American Medical Association, San Francisco, June 26, 1958.

arrest, whereas skeletal muscle will function even though the concentration is threefold. Cardiac hypoxia is produced by any factor that interferes with coronary circulation, as well as a frank low oxygen intake. This cardiac ischemia establishes a trigger zone that acts as a focus for ventricular fibrillation. Types of hypoxia and their causes include (1) anoxic, due to respiratory obstruction, low inspiratory oxygen level, or hypoventilation; (2) anemic, due to hemorrhage or anemia; (3) stagnant, due to shock, cardiac inefficiency, hypotensive drugs, or spinal anesthesia; (4) histotoxic, due to overdosage of anesthetics; and (5) metabolic, due to high oxygen demand. Hypoxia is frequently associated with, and made more dangerous by, hypercapnia.

Parasympathetic Stimulation.—Though formerly there has been skepticism regarding the vagus reflex, some reports seem to establish beyond reasonable doubt that tracheal, laryngeal, hilar, ocular, and mesenteric stimulation can produce cardiac inhibition by initiating vagus reflexes. A number of factors and agents potentiate this action. Hypoxia, hypercapnia, barbiturates, and cyclopropane are common causes.

Neostigmine is used freely as an antagonist to tubocurarine and other relaxants with similar action. It is important to remember that, unless the vagus is adequately depressed by atropine, this drug produces powerful stimulation which can (and has) initiated cardiac arrest.

Sympathetic Stimulation.—Guedel postulated that ventricular fibrillation could be produced by epinephrine released by emotional trauma incident to the induction of anesthesia.[12] The high incidence of cardiac arrest during induction lends support to this theory. Of course the danger of administering epinephrine or posterior pituitary injection (Pituitrin) in conjunction with cyclopropane anesthesia is well known. Ventricular fibrillation is to be anticipated. The preoperative preparation of the patient with adequate sedation is still vital. A recent tendency to belittle the euphoric effects of morphine is ill founded.[13] Several million narcotic addicts testify that morphine produces psychic effects that cannot be obtained with other sedative drugs.

Overdosage.—An overdose of practically any anesthetic agent will produce cardiac irregularities, vasomotor depression, and asystole. Doubtless some of this effect is hypoxic in nature, but many agents have a direct effect on the heart muscle or its conduction mechanism. The role of chloroform and ethyl chloride is well recognized. The other recently popular halogen anesthetics, trichloroethylene (Trilene) and halothane (Fluothane), seem to have similar properties, and great caution must be observed when using these drugs, for reports of cardiac arrest after their use are becoming common.[14] It is easy to give an overdose of any agent to a patient when, as is common, assisted or controlled respiration is being used.

Under normal circumstances overdose produces respiratory depression which by reducing ventilation tends to limit the amount of gas inhaled. However, when hyperventilation is artificially induced, an excess can be pumped into the circulation without the ordinary signs of deep anesthesia being present. The result is hypoxia from vasomotor depression and asystole from direct myocardial paralysis.

Trauma.—The heart may be directly embarrassed during intrathoracic surgery. This is undoubtedly a cause of the high incidence of cardiac arrest during these operations. There may be pressure on the auricles or great vessels preventing adequate filling. Wiggers describes also the onset of ventricular fibrillation by direct injury to the heart. This may be produced by external trauma as well as by direct interference with cardiac action.

Other Causes.—Less common causes of cardiac arrest to be mentioned in passing are artificially induced hypothermia and potassium or procaine intoxication. References to these are also appearing with increasing frequency.

The presence of preexisting cardiac disease, of course, makes the heart more susceptible to arrest from any of these causes. Furthermore, a damaged heart is much more difficult to restart or, restarted, to be maintained permanently with a regular efficient beat.

Diagnosis and Treatment

Diagnosis.—The diagnosis cannot be made without close observation of the patient. No anesthesia can be conducted "in absentia." A careful, conscientious, and competent individual must be in attendance constantly. Every breath must be noted, the pulse should be palpated constantly, and the blood pressure should be checked from minute to minute. An experienced anesthesiologist can often suspect cardiac distress by simple observation of the patient. Irregularities, bradycardia, or sudden hypotension are warning signs. The diagnosis is established not by electrocardiogram, or even auscultation, but by the absence of a palpable pulse in a major vessel. Treatment must be instituted without a moment's delay.

It is hoped that this presentation, by stressing that errors in technique or judgment are responsible for most cardiac arrests, might make discussion of treatment superfluous. One ounce of prevention is still worth many pounds of cure, for even under the best circumstances the results of treatment are unsatisfactory. The mortality, as quoted by various authors, is as follows: Bergner,[6] 35%; Ruth and coworkers,[15] 40%; Blades,[10] 50%; Lahey and Ruzicka,[2] 62%; Briggs and associates,[4] 63%; Freeman and coworkers,[16] 65%; and Barber and Madden,[17] 66% (average, 54.4%).

These statistics unfortunately do not give any information on one of the most distressing aspects of this subject. Many patients, listed as having recovered from cardiac arrest, undoubtedly are doomed to a hopeless vegetative existence due to cortical damage from cerebral anoxia.

Treatment.—The treatment of cardiac arrest has become well standardized and need not be discussed in detail. Artificial respiration with an adequate airway must be instituted as soon as the diagnosis is even suspected. No time should be wasted in intubation at this time. In many cases of simple hypoxia, reoxygenation will reestablish the heartbeat, but this must not be relied on. The chest must be opened immediately and alternate manual compression and decompression of the heart—not "massage"—instituted. The rate should be as rapid as diastolic filling permits, though most operators become fatigued rapidly if rates above 100 per minute are attempted. One should pause occasionally to see if spontaneous beating is resumed. Blood volume must be rapidly restored by intravenously given fluids and/or blood.

The tone of a flaccid heart may be restored by 1:1,000 epinephrine solution (5 cc.) directly injected. Its tendency to produce ventricular fibrillation must be recognized. Should this occur, electroshock with domestic current or a special defibrillator may stop the irregular contractions and allow massage to restore regular rhythm. Procaine by direct injection, topical application, or intravenous injection is recommended in an effort to overcome fibrillation by decreasing cardiac irritability.

It is difficult to predict a successful result. Patients who are moribund or have preexisting cardiac pathology will respond poorly, if at all. Each case must be individually evaluated before treatment is abandoned. Hosler[18] reported complete recovery after eight hours of continuous cardiac massage.

Successful resuscitation depends on (1) the immediate reestablishment of cardiac and cerebral oxygenation and (2) a more deliberate restoration of the spontaneous heartbeat.

Conclusions

I would make a plea to all exponent's of the art of anesthesiology that they be diligent and conscientious in preventing the tragedy of cardiac arrest. The reputation of this profession and the lives of the patients are at stake. Avoid hypoventilation with its vicious offspring, hypoxia and hypercapnia. Protect the patient against noxious reflexes by proper and adequate premedication. Mistrust the halogens. One agent well understood and administered still is more valuable than a polypharmaceutical barrage, of which the evaluation is difficult. Keep it simple, be watchful, be careful, be safe.

ARTERIOGRAPHIC STUDIES OF THE CORONARY ARTERIES IN ISCHEMIC HEART DISEASE

Alan P. Thal, M.D., L. Stephen Richards, M.D., Richard Greenspan, M.D.
and
M. John Murray, M.D., Minneapolis

The coronary arteries have been visualized in unanesthetized patients by injecting a radiopaque medium through a catheter into the ascending aorta. After premedication with meperidine and atropine, the catheter is introduced by way of the brachial artery and inserted until its tip lies about 2.5 cm. above the aortic valve. Special techniques have been developed in order to predetermine the phase and duration of the injection, since 40 to 55 cc. of the radiopaque medium must be injected within 0.8 to 0.6 seconds and the subsequent film exposures must be properly timed. The most convincing sign of coronary artery disease is the roentgenographic finding of occlusion of a major vessel. Of the four illustrative case histories here given, two concern patients who had been considered for cardiac surgery because of signs and symptoms of angina pectoris; the arteriographic demonstration of normal coronary systems in both cases was decisive in planning subsequent treatment. Recently injections have been made during the first half of the cardiac cycle starting at systole. This has reduced the volume of contrast material needed by half without affecting the clarity of the arteriogram. In over fifty studies there have been no complications.

Recently developed techniques[1] permit the regular visualization of the blood supply of the heart in the unanesthetized patient. The fine detail of the studies now obtainable affords not only the means of precise localization of the occluding lesions of the major coronary vessels but also a detailed picture of the collateral vascular development. Apart from its investigative use, coronary arteriography is of value in elucidating difficult clinical problems and also in providing objective evidence of coronary disease prior to myocardial revascularization. The present paper serves to outline techniques recently developed in this institution. Representative cases will be illustrated.

Materials and Methods

Injection Apparatus.—In essence, the injection apparatus consists of a compressed nitrogen-driven syringe fired by a solenoid valve. The radiopaque medium in the syringe, being highly viscous, is warmed by a heat reflector. This injector is capable of delivering 65 cc. of a 90% solution of diatrizoate (Hypaque) sodium through a size 330 polyethylene catheter in one second. The detailed construction of the injector and delay circuit have been described in another paper.[1a]

Delay Circuit.—Our experimental and clinical studies have regularly shown that the best delineation of the coronary vessels is obtained by a rapid injection of concentrated dye timed to start at the beginning of systole and continue for one cardiac cycle. At heart rates from 60 to 80 beats per minute, the injection is carried out over a period of 0.8 to 0.6 seconds. To obtain precisely timed injections, a variable delay circuit has been utilized. The circuit is triggered by the R wave of the electrocardiogram and the duration of injection is varied according to the heart rate.

Catheterization of the Ascending Aorta.—While it is possible to gain access to the ascending aorta in various ways, it has seemed safest to us to adopt the route of the brachial artery. The artery is carefully exposed in the upper part of the arm, and a transverse arteriotomy is made. With use of a flexible catheter guide, the catheter is directed into the ascending aorta and positioned under the fluoroscope to lie about 1 in. above the aortic cusps. The guide is then withdrawn. After considerable trial, we have found a lateral-opening, closed-tip, size 330 polyethylene catheter to be most suitable for these studies. At the conclusion of the procedure, the catheter is withdrawn and a meticulous repair of the artery performed.

Preparation of the Patient.—Sedation is accomplished with meperidine (Demerol) hydrochloride, given intramuscularly prior to catheterization, and 0.6 mg. of atropine, given intravenously 10 minutes before the dye injection. The carotid arteries are manually compressed low in the neck during the injection to reduce the cerebral circulation of the opaque medium.

Radiopaque Mediums.—For detailed studies of the coronary circulation, it is necessary to use the newer concentrated mediums. Diatrizoate, in a 90% solution, has given satisfactory results in our hands. The viscous mediums require warming to body

perature prior to injection. The volume of ma-
ial used has varied from 30 cc. to 50 cc., depend-
on the size of the patient and the heart rate.

alibration.—With use of a two-channel record-
unit, a simultaneous electrocardiographic and
tic pressure curve tracing is made. The delay be-
en the peak of the R wave and the peak of systole is measured and the delay circuit calibrated accordingly. A trial run is then made with the injector excluded from the circuit. The precise phase and duration of injection is then recorded.

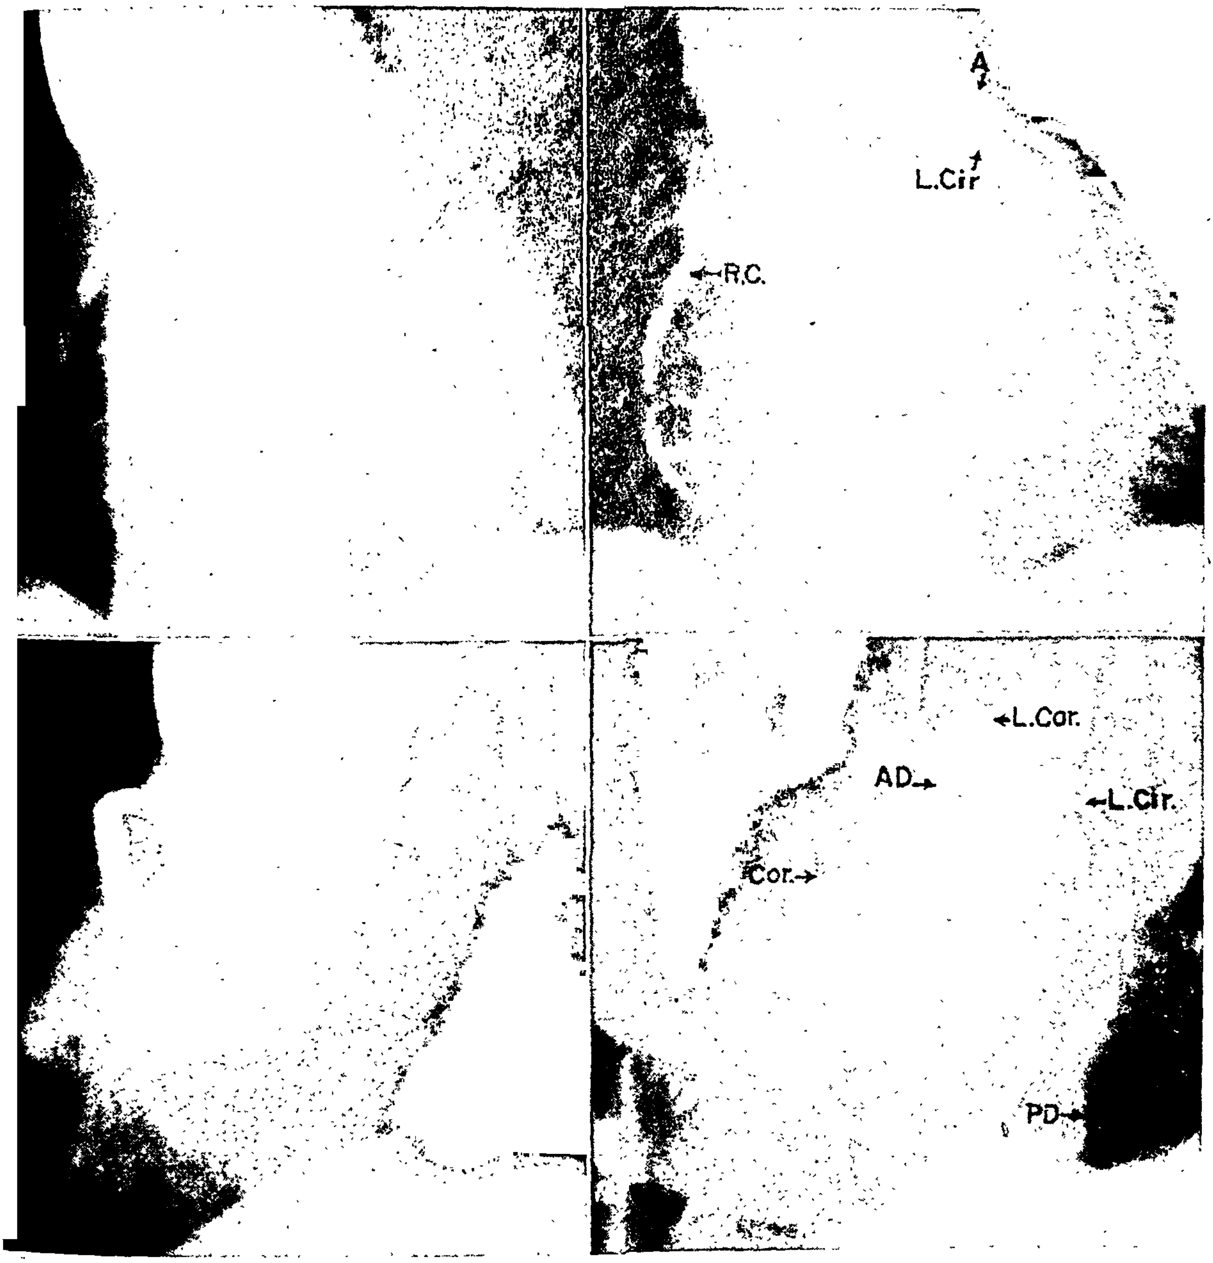

Fig. 1 (case 1).—Anteroposterior and lateral views of coronary arteriogram in patient with angina-like symptoms. Arteriogram shows entirely normal pattern. *L. Cor.* indicates left coronary artery; *R. Cor.*, right coronary; *L. Cir.*, left circumflex branch; *AD*, anterior descending branch; and *PD*, posterior descending coronary artery.

In general, at a pulse rate of 70 to 80 per minute, the actual injection can be made over 0.8-0.6 seconds. This allows for the injection of 40 to 55 cc. of radiopaque material.

Rapid Film Changer.—The Schonander biplane unit, which allows six films per second in two planes, has proved satisfactory for detailed studies of the coronary circulation. As has been shown in peripheral arteriography, films taken in one plane may give an erroneous idea of vessel caliber. The anterior descending branch of the left coronary artery is best seen in the posteroanterior view, while the right coronary and left circumflex branch are best studied in lateral view.

The following cases were selected to demonstrate the value of coronary arteriography both in the resolution of difficult clinical problems and in the investigation of the pathological anatomy in severe coronary sclerosis.

Report of Cases

Case 1.—A 55-year-old woman was first seen on March 18, 1958, with a three-year history of chest pain on exertion. The pain was described as being retrosternal with radiation down the left arm to the wrist. It would occur initially only on moderately severe exertion and, at that time, was promptly relieved by cessation of activity. The severity and frequency of the pain increased, requiring nitroglycerin for relief. When first seen, pain would occur spontaneously at rest and she had been taking meperidine, promazine (Sparine) hydrochloride, and occasional injections of morphine sulfate for relief. She was described as being extremely dependent on her doctors. She was apparently subject to moderately severe depression. This patient was referred to the Univer Hospitals for surgical revascularization of the heart. T physical examination revealed a mild degree of rheumat arthritis involving the proximal interphalangeal joints of hands only, a blood pressure of 120/90 mm. Hg, a pulse r of 84 per minute, which was regular, no evidence of placement of the apex beat, no abnormal heart sounds murmurs, and no evidence of congestive heart failure. electrocardiogram taken when she was at rest revealed abnormalities. In view of the patient's personality prob and her knowledge of the symptoms of coronary ar disease, it was felt that there was considerable doubt ab the diagnosis of angina pectoris. Accordingly, a coro arteriogram was performed. This is illustrated in figure 1 *is interpreted as showing a normal coronary system.* W the patient was confronted with this evidence, the chest pain disappeared. However, within a few days she developed pain in her legs, of similar character.

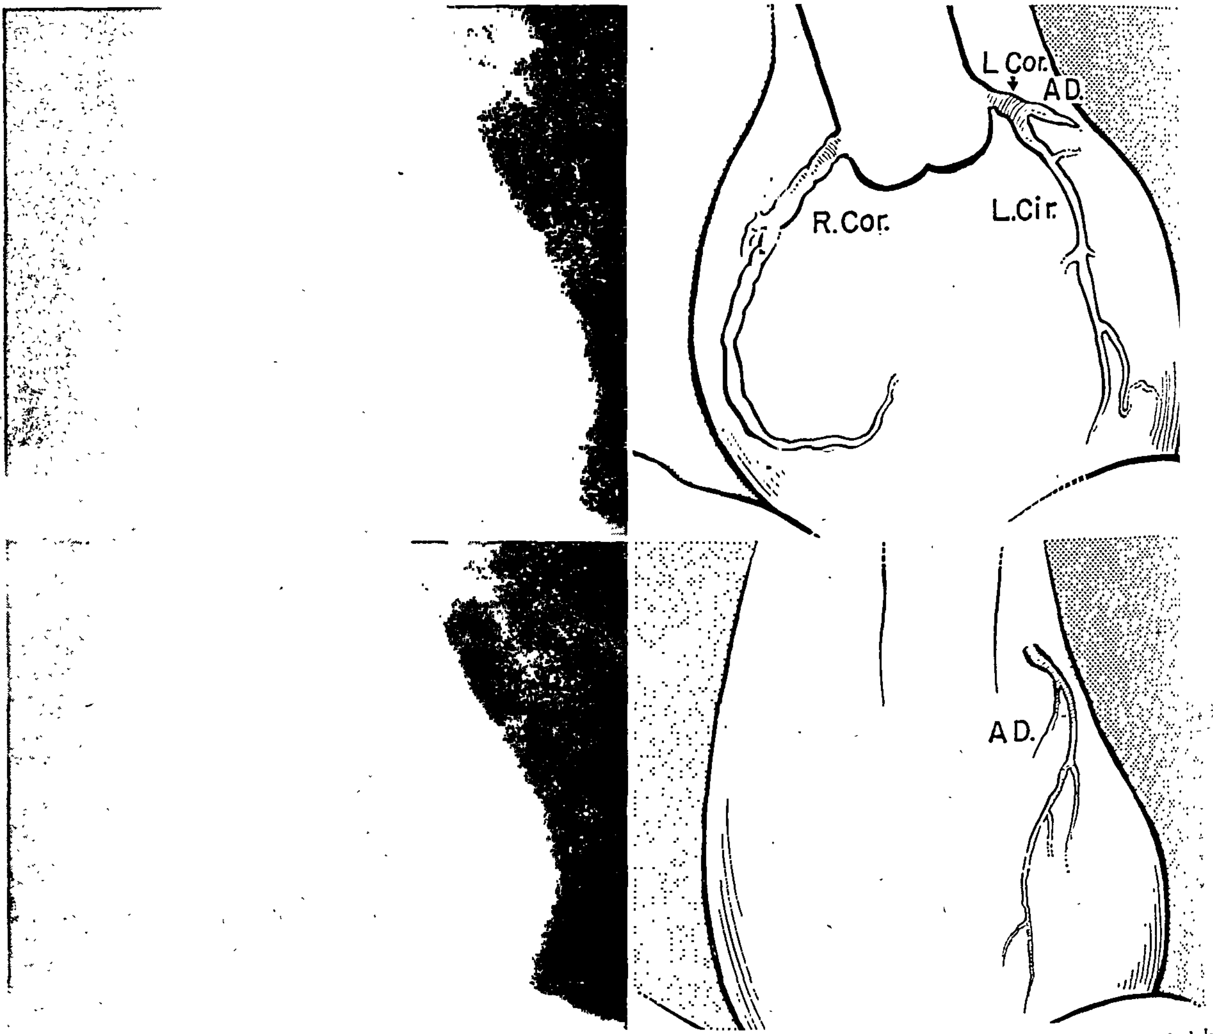

Fig. 2 (case 2).—Arteriograms with corresponding drawings (*top*), showing generalized narrowing and irregularity of whole coronary system with complete occlusion of anterior descending coronary artery near its origin and (*bottom*), taken several seconds later, demonstrating reflux filling of anterior descending coronary artery from collaterals over apex of heart.

Case 2.—A 53-year-old man was first seen on March 11, 1958, complaining of chest pain on exertion, which had been present for 18 months but had become worse since July, 1957. He first noticed the onset of retrosternal squeezing pain with radiation to both arms while working or walking. Initially, the pain was relieved promptly by ceasactivity or by taking nitroglycerin. The condition pro- sed so that at the time of admission even the mildest tion precipitated pain lasting up to 10 or more minutes. physical examination was entirely unrevealing, the d pressure being recorded at 140/85 mm. Hg, with no lence of cardiac enlargement, abnormal heart sounds, or murs. There was no enlargement of the heart on x-ray, the electrocardiogram showed inversion of T waves in ls 1, aVL, V_3, V_4, and V_5 consistent with myocardial iemia. *Coronary arteriograms* (fig. 2) *demonstrated com- e occlusion of the anterior descending branch of the* coronary artery, with diffuse atherosclerosis of the whole onary system. It is of interest that intercoronary collateral v was well established and there was retrograde filling the occluded anterior descending artery. This patient ob- ed *some immediate subjective improvement after peri-* dial poudrage.

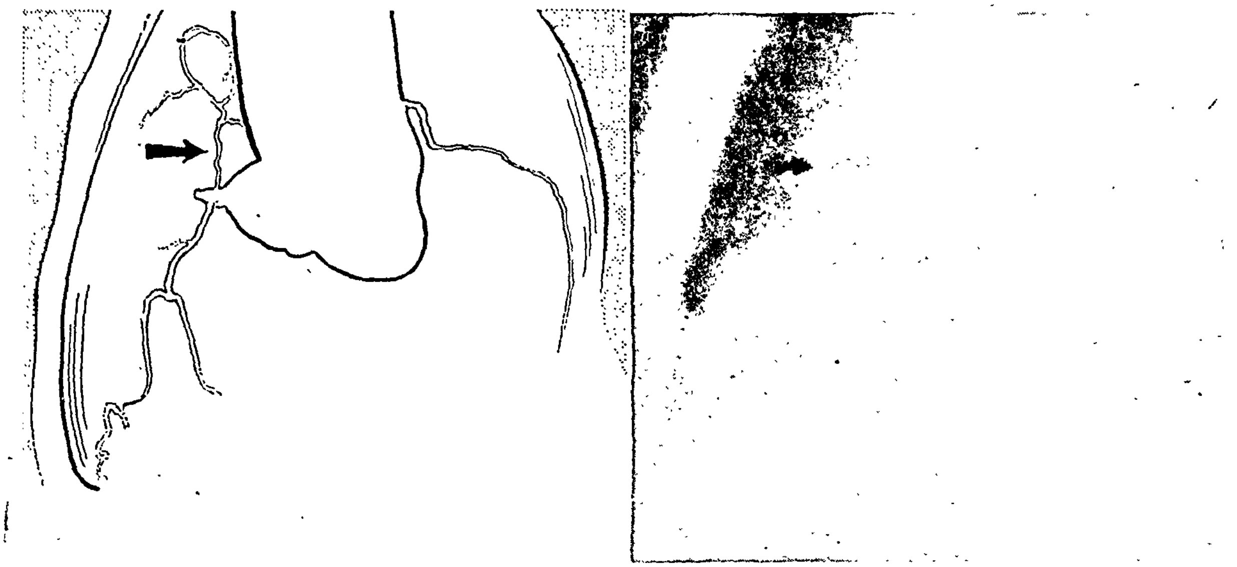

Fig. 3 (case 3).—Extreme coronary sclerosis with occlusion and recanalization of left main coronary. Lateral view shows extensive collateral vessels anterior to aorta. This trunk represents ramus ostii cavae superioris, which takes origin from right coronary artery.

Case 3.—A 52-year-old man was first seen on Dec. 20, 57, complaining of chest pain on exertion since 1955. tially, the pain occurred on exertion or in the early hours the morning, when it awakened him from sleep. It was rosternal, with radiation into the left arm to the finger- s. Initially, it was relieved by nitroglycerin, the efficacy of which became less as time went on. On May 27, 1957, he had an attack of severe chest pain at which time a diagnosis of myocardial infarction was made. After this he continued to have attacks of pain at rest and on mild exertion, as well as during the night. Physical examination revealed a blood pressure of 150/90 mm. Hg, no cardiac enlargement, and no congestive heart failure, but the presence of an atrial gallop in the apical region was noted. The electrocardiogram taken at rest was reported within normal limits, and the chest x-ray confirmed the absence of cardiac enlargement. The serum cholesterol level was recorded as 272 mg.%. Coronary *arteriograms revealed generalized narrowing of the whole coronary system with multiple and extensive occlusions of the anterior descending branch of the left coronary artery.* There was prominent filling of small extracardiac vessels at the base of the heart in the anterior mediastinum. These presumably represented expansion of the vessels over the pulmonary conus. Subsequently, the internal mammary artery was implanted into the myocardium. The patient tolerated this well. However, about two hours after operation he died suddenly in ventricular fibrillation. The extreme degree of atherosclerosis is illustrated in figures 3 and 4. The possibility exists that disruption of anterior mediastinal collateral vessels during mobilization of the internal mammary artery further diminished an already marginal blood flow to the heart.

Case 4.—A 24-year-old woman was first seen on Jan. 13, 1958. Heart trouble was apparently initially suspected at the age of 9 years, when a cardiac murmur was first noted and attributed to rheumatic fever. She remained reasonably well, however, apart from easy fatigability on strenuous exertion, until 1955, at which time she noticed shortness of breath spontaneously and on exertion. For one year she had noticed fleeting stabbing pains located in the center of the anterior part of the chest; this seemed to be worse after exertion. Two weeks before admission she had noticed a severe generalized crushing pain in the anterior part of the chest, lasting two minutes and associated with shortness of breath and sweating but apparently unrelated to exertion. Examination revealed no cardiac enlargement, a blood pressure of 100/70 mm. Hg, and a pulse rate which was regular at 68 per minute. There was no evidence of congestive heart failure, but there was a loud third heart sound audible both at the apex and along the left sternal border, while at the pulmonic area there was a moderately loud systolic murmur of the ejection type.

The pulmonary second sound was not accentuated and was normally split. The electrocardiogram revealed inversion of T waves in leads 2, 3, aVF, V_2, V_3, V_4, V_5, and V_6, as well as depression of the ST segments in leads 2, 3, aVF, and V_6. This electrocardiogram showed no change over one taken four years previously. Cardiac fluoroscopy revealed a heart well within the normal limits of size and configuration, although there was a question of right ventricular enlargement. Right heart catheterization was performed, and the findings were entirely within normal limits. It was felt that possibly this woman had an anomalous origin of one coronary artery to account for what resembled either ischemic heart disease or a myocardiopathy of unknown origin. A coronary arteriogram was taken. As shown in figure 5, this showed a completely normal coronary system.

Arteriographic Signs of Coronary Artery Disease

The most definitive sign of coronary arteriosclerosis seen on angiography is a complete or partial occlusion of a major vessel. This is most commonly seen in the proximal reaches of the anterior descending branch of the left coronary artery and may be manifested by a gradual tapering of the vessel lumen, by a complete and abrupt obstruction to the column of dye, or by an atheromatous encroachment on the lumen. Frequently, small tortuous vessels can be seen bypassing such an occlusion or feeding its distal portion by collateral from an adjacent artery. While these occlusions may form the most striking feature of a coronary arteriogram, diffuse disease of the whole system is shown by gross irregularity of the intimal surface and rigidity of the vessel during systole and diastole. In aged patients without evidence of myocardial ischemia, extreme tortuosity and microaneurysm formation is common. A complete and dynamic impression of the coronary topography in disease can only be secured by viewing multiple films taken in two planes. In this way, retrograde filling of an obstructed coronary artery may be seen in late films.

Another sign which is encountered only in patients with extremely advanced disease is stasis of radiopaque material in peripheral areas of the coronary circulation, where proximal obstructio has brought about considerable slowing of th blood flow. In two patients with intractable angin pectoris at rest, we have demonstrated extensiv atrial and anterior mediastinal collateral vessel These vessels appear to be expansions of the no mal small vessels at the base of the heart emanatin from both right and left coronary arteries and normally ramifying over the atria, the pulmonary conus, and the superior vena cava. It is quite possible that they represent an expanding collateral circulation which develops as a result of extreme ischemia. The branching vessels seen anterior to the aorta in figure 3 represent the ramus ostii cavae superioris [2] which supplies the sinoatrial node and forms collaterals around the atria, with the pericardiophrenic artery, and other extracardiac vessels.

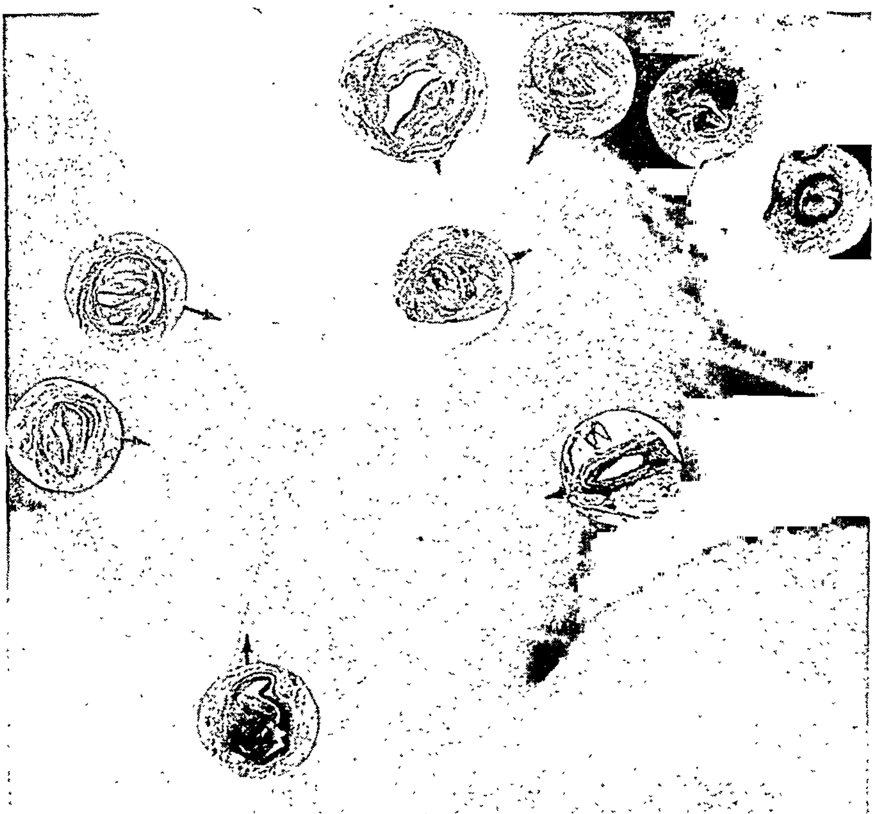

Fig. 4 (case 3).—Sections of coronary arteries shown superimposed on arteriogram of patient with severe angina at rest. Extreme degree of narrowing extending far out into periphery is shown.

Comment

In 1955 we developed techniques for direct anastomoti bypass of experimental coronar occlusion.[3] This work was base on the premise that the coronar arterial disease was often localized to the first portions of th main coronary arteries. Our subsequent arteriographic studie suggest that this concept is erroneous. The patient with angin on effort appears to have diffus disease of the whole coronar arterial system, while in the patients we have studied with angina at rest there appears to b an additional impairment of th collateral circulation. In the 5 patients we have now studie there have been two instances o segmental arterial block. Both o these patients are asymptomati This situation is quite analogou to that seen in the experimenta animal, which survives a punctate occlusion in the presence o an otherwise normal coronary vasculature. Thes findings then make it appear unlikely that direc coronary artery surgery will be effective in th treatment of ischemic heart disease.

While the diagnosis of myocardial ischemia ca frequently be made with great accuracy on th basis of the history and electrocardiographic findings, yet there remains a small but definite group o patients in whom the diagnosis remains in doubt i spite of careful clinical study. These problem case may readily be resolved by coronary arteriograph which, in our experience, may now be done wit small risk and little discomfort to the patient.

It is now apparent from the results of various types of surgical procedures for myocardial revascularization that there is a strong functional element in many patients with angina pectoris. The extent of this functional overlay can be judged from the occasional patient with established angina pectoris who obtains complete relief of his symptoms after nothing more than a skin incision. Within the last eight months, among the patients referred to this hospital for myocardial revascularization operations, four were found to have entirely normal coronary arteriograms and in each instance the chest pain was greatly ameliorated or disappeared after the patient was informed that the coronary system was normal. The percentage of such patients included among the successful results of myocardial revascularization is unknown, but it is apparent that coronary arteriography would be of value in eliminating this type of patient as a surgical candidate.

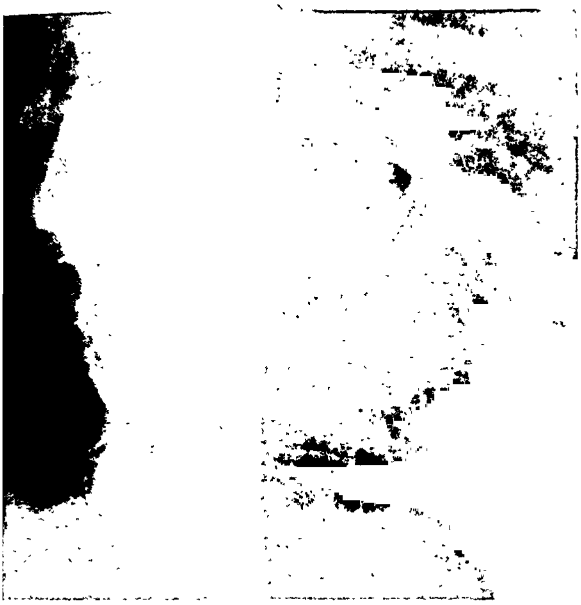

Fig. 5 (case 4).—Coronary arteriogram, showing entirely ıormal pattern. Large, smooth-walled vessels may be conrasted with extreme narrowing seen in figure 3.

Quite apart from the diagnostic value of these studies, it may be possible with increased experience to formulate a more accurate prognosis in coronary sclerosis based on such factors as the extent of the disease and the collateral response. Last, but perhaps most important, the method offers a basic research technique for evaluation of the early vascular reactions to ischemic myocardial insult.

Summary

Recently developed techniques for coronary arteriography have made possible a quality of arteriogram which allows critical study of the coronary arterial system in patients with severe coronary sclerosis. In four representative cases, two patients originally referred for surgical treatment were shown to have normal coronary vessels. The most definitive roentgenologic sign of coronary artery disease is complete or partial occlusion of a major vessel.

This study was supported by grants from the U. S. Public Health Service and the Minnesota Division, American Heart Association.

The diatrizoate sodium used in this study was supplied as Hypaque-M, 90%, by Winthrop Laboratories, New York.

PROGNOSIS OF MYOCARDIAL INFARCTION.—As emphasized in the 1941 and 1956 reports, the most important clue favoring longevity and a return to a normal program of life [in 200 patients with coronary thrombosis and myocardial infarction] was found to be the degree of completeness of recovery after the first month of convalescence from the acute attack. Of the 24 cases who showed neither myocardial nor coronary insufficiency, 18 (75%) survived five years, while the average survival of these 24 cases was 12 years. Among those who, free of complications, completely recovered from their attack, the eventual cause of death was most commonly coronary, either recurrent thrombosis or sudden death, with or without evident angina pectoris. . . . Not infrequently during the 1920's the treatment and cooperation of patients . . . were inadequate. . . . Our attitude concerning the prognosis of coronary thrombosis with myocardial infarction will undoubtedly be much more optimistic in the future than it has been in the past because of the recognition of mild cases, the better treatment and program after recovery, and the more satisfactory understanding and cooperation of the patient.—P. D. White, M.D., E. F. Bland, M.D., and S. A. SOME NEW CONCEPTS OF CORONARY HEART DISEASE

RESULTS AFTER SURGICAL OPERATION

Claude S. Beck, M.D., David S. Leighninger, M.D., Bernard L. Brofman, M.D.
and
Jess F. Bond, M.D., Cleveland

In disease of the coronary arteries the myocardium is handicapped and endangered by ischemia; correction of this condition is the aim of the operation described here. With the patient under general anesthesia, the pericardium is opened. The parietal pericardium is abraded. A constricting ligature is usually placed about the coronary sinus, and before the end of the operation it is tightened to narrow the sinus to a diameter of 3 mm. Powdered asbestos is lightly sprinkled over the surface of the heart. The parietal pericardium is not closed, but the pericardial fat is sutured over the exposed surface of the heart. The mortality rate from this operation was found to depend entirely on how high a percentage of patients with advanced coronary disease were included in the series. In 110 patients with initially poor prognosis approaching the terminal stage, the hospital mortality was 11%; among the remaining 234 patients, the hospital mortality was 3%. Subjective benefits from the operation included relief from pain and reduced intake of medicaments. Objective evidence of benefit included return to gainful occupation, rise in skin temperature of extremities, disappearance of arrhythmias, and increased force of heartbeat as recorded by ballistocardiogram. The lasting effects of the operation contrasted strongly with the temporary effects of medication.

Direct operative procedures carried out on the heart and on the coronary blood vessels of dogs have yielded some new and different points of view concerning coronary heart disease.[1] Reference is made to it as a background for this report, which concerns the operation on humans.

Effective Treatment

The starting point for effective treatment of coronary heart disease concerns blood supply to ischemic muscle. Any medicament or any surgical operation that increases the amount of blood in ischemic muscle (distal to stenosis or occlusion in an artery) is obviously beneficial. This statement may be considered as an axiom or as a self-evident truth concerning treatment of this disease. Addition to this amount of blood is beneficial; reduction has the opposite effect.

Total Coronary Artery Inflow.—The myocardium requires a certain amount of blood to sustain the heart beat. The total capillary flow for the human is about 250 cc. per minute and for the dog about 100 cc.[2] The normal coronary arteries are capable of carrying much larger quantities than these amounts, and, therefore, the arteries can be narrowed severely before inflow becomes inadequate. Inadequate inflow is one of the factors that kills, and it occurs with or without infarct in the muscle.

Several surgical operations have been devised to increase total inflow. In general, the statement can be made that the heart resists the entrance of outside blood. It is not impossible to add blood to the heart because specimens exist which demonstrate blood vessels between grafts placed on the heart and the heart itself, and these are large enough to carry blood, but they cannot be produced with any degree of regularity. Perhaps better grafting methods can be developed in the future. Another approach to augment inflow consisted of putting arterial blood into the coronary sinus and diverting it in a retrograde direction through the capillary bed. This works satisfactorily for about six weeks, and then intimal thickening in the veins begins to block off inflow. However, the heart is protected by another mechanism (to be discussed later) after retrograde flow no longer occurs. Another possibility for the addition of blood concerns surgical procedures on the diseased arteries themselves.

Restoration of Lumina of Coronary Arteries: To clean out the debris from these arteries (endarterectomy) and to reestablish their lumina is an attractive idea because, being an extirpation procedure, it is readily understood. The question is: "Can it be done successfully in arteries of such small size and also when the disease is usually widespread and rarely localized to one short segment of artery?" Experience with this procedure is being

Read before the Section on Surgery, General and Abdominal, at the 107th Annual Meeting of the American Medical Association, San Francisco, June 26, 1958.

obtained, and this should give an answer to this query. Our experiences on the dead heart indicated that endarterectomy will probably not be successful. The disease usually extends into secondary arterial branches, and manipulation of a stenosed artery may produce occlusion of the artery.

Distribution of Blood in Coronary System: The heart enjoys an even distribution of the blood that gets through the diseased arteries. In many patients with the disease there is enough blood getting into the heart to provide adequate function, but its distribution is at fault. It is an uneven or checkerboard distribution, and this produces pain and self-electrocution of the heart. Indeed, this is the most common cause of death. It occurs when the patient is on the golf course, while he is shoveling snow, watching athletic contests, in the office, at work, and so on and often in hearts that anatomically are too good to die. It is a physiological type of death, and the coroner or pathologist is often hard pressed to explain it. There may be no infarct and no occlusion, only narrowing of an artery. In the experimental laboratory and by successive operations all coronary arteries in the dog were occluded except for a 1-mm. lumen in the circumflex artery, and these dogs were active and in good health.[3] The factor that made these occlusions possible was the presence of a good set of intercoronary vessels that were produced by surgical operation before the arteries were occluded, so that a red blood cell, once it got past the stenosis in the circumflex artery, could go anywhere within the substance of the heart where it was needed most. Enough blood to support the heart beat can go through an opening of 1 mm. in diameter. In the human enough blood to support the heart beat can go through a stenosis of 1.5 mm. in diameter. A good set of intercoronaries is necessary to prevent fibrillating currents as stenosis and occlusion progress to the terminal stage of inflow reduction.

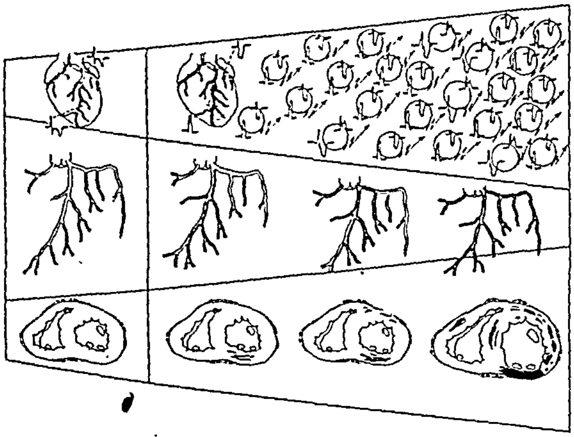

Fig. 1.—Death factors in coronary heart disease. *Top*, uneven distribution of blood producing oxygen differentials and electric condition that can destroy heart beat. *Center*, reduction of inflow; not enough blood to support heart beat. *Bottom*, muscle destruction; not enough muscle to maintain adequate circulation; death results from myocardial failure.

Muscle Failure.—Another way by which the disease kills is by destruction of muscle. One artery after another becomes occluded; one segment of muscle after another becomes scarified; there is not enough muscle to produce effective blood pressure; the patient dies in failure. The heart escaped fibrillation while these occlusions occurred. The electric alterations produced by occlusion were never strong enough to kill, and, indeed, the total inflow might be adequate to support the heart beat. This has been referred to as muscle death. The three death factors in the disease are shown in figure 1.

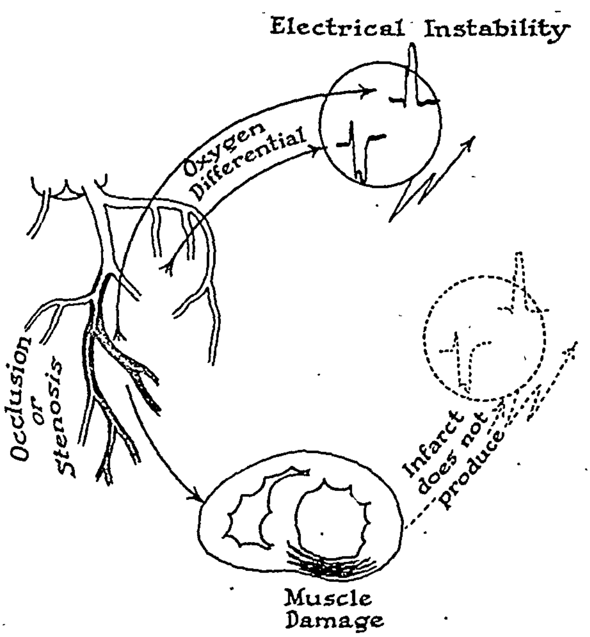

Fig. 2.—Two sequelae which may occur after stenosis or occlusion of artery. One is unstable electric condition due to oxygen differentials in muscle and other is infarct.

Two sequelae of occlusion are shown in figure 2. Occlusion produces an oxygen-differential in contiguous areas of muscle which in turn produces anginal pain and an electric condition that can fibrillate the heart. Also, occlusion may produce death of muscle. These two sequelae are not related. The heart can electrocute itself in the absence of an infarct. Likewise an infarct can develop without electrocuting currents. It is well to bear these facts in mind because the diagnosis of a mild occlusion is often made and the patient dies. A human can have a small infarct but not a mild occlusion. A mechanism that has the potential of death should scarcely be referred to as "mild."

Value of Operation.—There are certain things that surgical operation can do and there are certain things that it cannot do. Let us consider the three death factors of the disease. For oxygen differentials, anginal pain, and electric instability surgical operation is beneficial, and it is beneficial because it produces intercoronary vessels. For inflow reduction which is approaching the terminal stage surgical operation is probably not effective; perhaps more effective methods can be developed. For muscle damage operation is not effective; muscle cannot be restored. Self-electrocution is always a threat in the presence of coronary artery disease. Intercoronaries are always a protection against this factor, and they protect until inflow reduction becomes terminal.

Blood Supply into Ischemic Muscle, as Influenced by Glyceryl Trinitrate and by Operation.— A large number of backflow determinations have been made in our research laboratory, and a considerable experience with this method of study has been acquired. These measurements are important because they are a measure of the amount of blood that is in a segment of ischemic muscle. This method measures the axiom of treatment. These measurements are done by ligating the circumflex artery at its origin and then cutting the artery distal to the ligature. A cannula with two connections is inserted into the cut artery so that backflow from the artery can be collected and measured and also for perfusion of the artery between determinations by a connection with the carotid artery. Measurements of backflow are made for 30 seconds; then the artery is perfused from the carotid in order to preserve the heart beat.

The effect of glyceryl trinitrate was measured by 43 determinations on 21 normal dogs. This drug increased backflow an average of 0.88 cc. or 10 drops per minute. The range was from 0.0 to 4.0 cc. Statistically these figures are highly significant. The drug-effect lasts for about five minutes. The statement can be made that this drug adds blood to ischemic muscle from adjacent muscle with a good blood supply. This addition of blood reduces the differences in oxygen content in muscle and helps to bring about a more even distribution. This in turn reduces pain and, no doubt, protects the heart. The drug-action is temporary. This drug does not produce intercoronary vessels. The Beck operation adds 4.7 cc. or 47 drops per minute to the quantity already there, and it is a permanent addition. Patients having used this drug while on a medical regimen and then later having gone through surgical operation are in a position to evaluate and compare both forms of treatment. The clinical benefit obtained by these patients from this drug and from surgical operation gives new significance to 10 drops and 47 drops, respectively, per minute to ischemic muscle as produced by these two forms of therapy.

Preoperative Considerations

The ideal patient for operation is one who has anginal pain and an adequate total arterial inflow. The patient with adequate inflow needs a more even distribution and operation accomplishes this. It need scarcely be stated that anatomic disease in muscle and/or arteries cannot be eradicated by surgical operation. A patient with severe muscle destruction and failure is not acceptable for operation nor is the patient with terminal disease in the arteries. Inflow reduction approaching the terminal stage may occur in hearts that do not have a gross infarct. These hearts are irritable at operation, and they are susceptible to fibrillation. This condition cannot always be recognized before operation.

The studies carried out before operation are not more extensive than necessary. They consist of fluoroscopic and x-ray examination of chest, electrocardiogram with or without exercise, the ordinary laboratory tests, and special studies only when indicated. Diagnosis is often based on a good history. If there is any doubt concerning diagnosis, operation is delayed or not done. Operation is delayed if there is any recent activity in the disease. It is not done within six months after an infarct. A serious program against obesity is carried out before operation. Almost all of our patients stop smoking and do not take it up later. The mental attitude of the new patient is helped by talking to patients who have been operated on. The patients operated on are very willing to do this. The patient is told that if his blood pressure falls while he is under anesthesia, operation will not be done. This reduces the disappointment if it is not done. He is told to expect incisional pain and that pills for anginal pain will be at his bedside. He is told that when he awakens in the recovery room he will have a tube in his nose for oxygen, that a tube will be in his chest for drainage, and that a needle will be in a vein for administration of fluid.

Instruction concerning physical therapy is given. This consists of several exercises. The patient is taught postural drainage lying on the right side at a 45-degree angle for 15 minutes. After postural drainage the patient coughs for about five minutes while an attendant splints the lower part of the chest with a towel drawn taut around him. He is taught diaphragmatic and abdominal breathing. These muscles are used while the chest is in an expanded position. Arm and shoulder exercises are done. The range of motion is determined before operation, and this amount of motion is obtained after operation. Postural drainage, coughing, diaphragmatic breathing, and arm-shoulder exercises are taught before operation and are resumed the day after operation and done three times daily for one week. They reduce pulmonary complications and prevent the development of a frozen shoulder. They also reduce the reaction of being an invalid after operation, and the patients do not object to them after they once get started.

Technique of Operation

The patient is given a general anesthetic. An intratracheal tube and a mechanical respirator are used. The patient is connected to a cardioscope. Relaxing drugs and light anesthesia are used. The patient is turned on his right side. If the arterial pressure should fall below 90 mm. Hg and if it does not recover within 30 minutes without the use of pressor drugs, use of the anesthetic is discontinued and operation is not done. A fall in pressure indicates severe inflow reduction. The incision is placed between the fifth and sixth costal cartilages and ribs and is about 20 cm. in length. The latissimus dorsi muscle is elevated, and the intercostal muscles are undercut (fig. 3). A self-retaining retractor is placed, and the ribs are spread apart about 10 cm. (fig. 4).

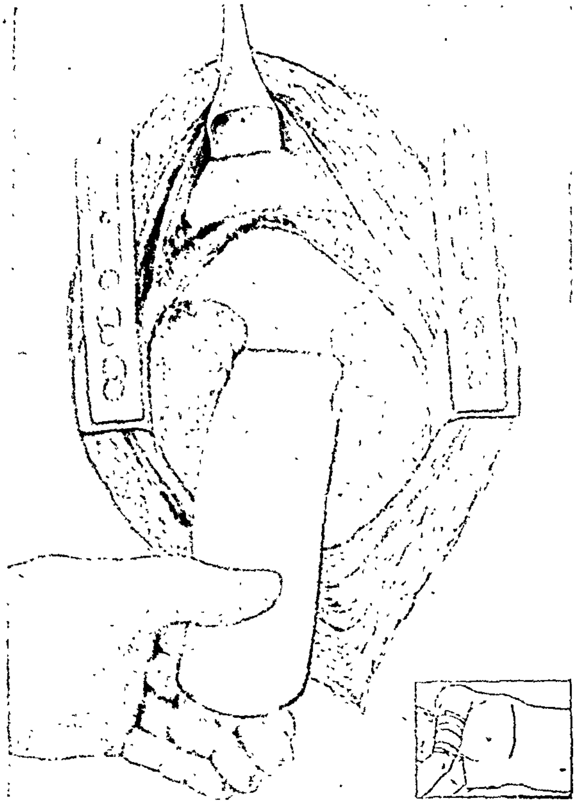

Fig. 3.—Latissimus dorsi muscle is elevated. Intercostal muscles are cut between fifth and sixth ribs for length of about 25 cm. Inset shows position of patient on operating table and location of skin incision.

The blood supply to the fat on the pericardium is preserved as much as possible. The pericardium is opened from apex to base, and traction sutures are placed in the pericardium (fig. 5). The heart is examined and data are obtained as follows: the size of the heart—normal or enlarged; character of beat—uniform, a roll (indicating a scar), or reduced or absent pulsation in any area; a bulge or aneurysm; irritability to touching; soft, thickened, or calcified common left artery as indicated by light palpation with a finger; streaking, beading, or reduced pulsation in descending artery and its branches and the branches from the circumflex artery; and infarct on the surface. The heart is tipped up for examination of the posterior surface (fig. 6). Occasionally this cannot be done because of irritability.

If the common left artery is soft one can conclude that inflow is satisfactory, that distribution is the problem, and that a favorable result can be expected. If the anatomic disease is not severe, a good prognosis can be given; if it is severe, it is classified as salvage and a guarded prognosis is given. The lining of the parietal pericardium is abraded; care is taken not to stretch or contuse the left phrenic nerve. The heart is gently rotated to expose the coronary sinus. A needle carrying a piece of silk is passed around the sinus about 2 cm. from the point where it empties into the right auricle. Usually the middle cardiac vein empties into the sinus beyond this constricting ligature. If the heart is enlarged so that exposure of the sinus is difficult or if the heart is irritable or if the sinus is covered with fat and cannot be located, this part of the operation is omitted.

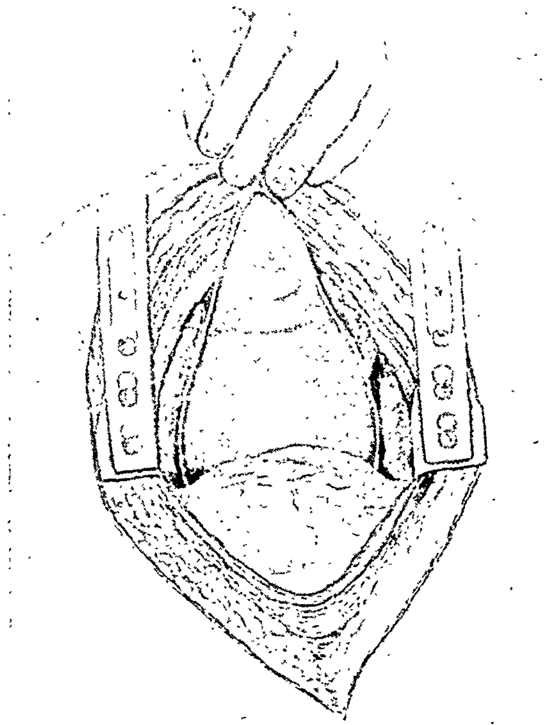

Fig. 4.—Special retractor on lung. Left phrenic nerve and fat on outside of pericardium are shown.

The next step consists of gentle abrasion of epicardium between branches of the arteries and making a light application of 5% aqueous solution of trichloroacetic acid freshly prepared to the surface of the heart between the secondary branches of the major coronary arteries. If the heart is irritable, abrasion is omitted. The next step consists in narrowing the coronary sinus to a diameter of 3 mm. This is done by tying a knot in the silk already placed over a probe of this size and then removing the probe. A light sprinkling of powdered asbestos is placed on the surface of the heart. The parietal pericardium is not sutured, but the fat is sutured so as to cover the anterior aspect as much as possible as a graft. This complete procedure is carried out when the heart is stable and tolerates manipulation. If the heart is irritable, the operation is limited to application of trichloroacetic acid and powdered asbestos. A tube with an underwater seal or suction is placed low in the midaxillary line for 48 hours. The intercostal nerves on the left are injected with tetracaine (Pontocaine) hydrochloride before closure is done. Oxygen is given through an intranasal tube for several hours.

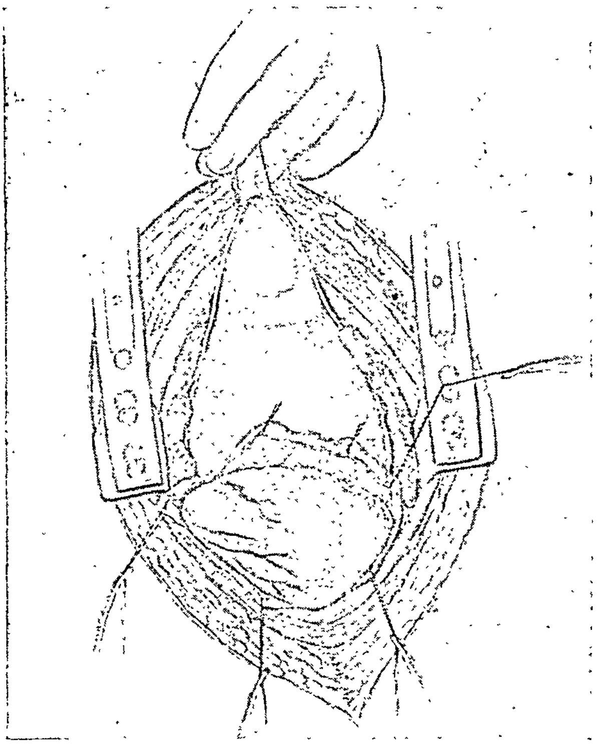

Fig. 5.—Pericardium opened medial to phrenic nerve; traction sutures in pericardium; heart exposed. Branches of descending and circumflex arteries are seen. Infarct is in left ventricle. Branches from descending ramus showed reduced pulsation.

It is possible to do the operation with a low mortality. We did 100 consecutive operations with zero mortality. If patients with severe inflow disease are selected, then there will be some mortality. Such patients would have a limited expectancy without operation. When operating on hearts that are very irritable, the extent of the procedure is reduced. Some of these hearts can scarcely be touched at operation. In such cases the application of trichloroacetic acid and asbestos powder constitute the operation.

Use of Drugs.—All patients are digitalized before operation. The drugs used preoperatively are morphine, pentobarbital sodium, and atropine. In the operating room the patient is given glyceryl trinitrate if he has anginal pain and promethazine (Phenergan) hydrochloride, 0.0373 to 0.050 Gm., is given intravenously if the patient is apprehensive. The patient is well ventilated with oxygen. Thiopental (Pentothal) sodium and succinylcholine chloride are given intravenously. An intratracheal tube is inserted. Respiration is usually assisted because of apnea and on resumption of spontaneous respiration *d*-tubocurarine chloride is given and respiration is taken over by the Rand-Wolfe respirator. The use of a mechanical respirator is recommended. Anesthesia is maintained with nitrous oxide and a small amount of ether. Tubocurarine is given as necessary to control the motion of the diaphragm. Plane 1 anesthesia is used throughout the operation, and analgesia is used for closure. The patient is awake when the intratracheal tube is removed.

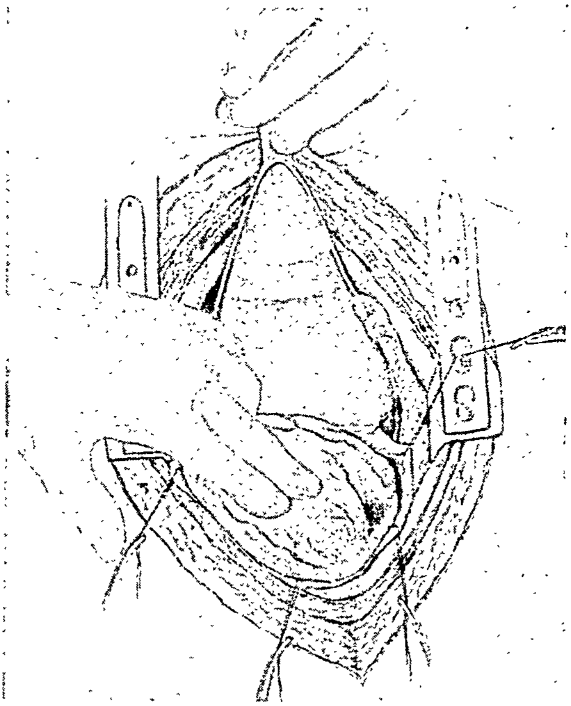

Fig. 6.—Apex elevated showing posterior aspect of heart.

If the pressure falls or if the heart rate is rapid or irregular, use of anesthetic is discontinued, and the lungs are well ventilated for several minutes. Mephentermine (Wyamine) in a dosage of 15 mg. is given intravenously for its pressor effect. Procainamide (Pronestyl) hydrochloride, in dosage of 50 to 100 mg., is given intravenously to reduce the irritability of the heart. A slow heart rate is preferable to a rapid rate, and atropine should be used only with caution. If the rate is 120 per minute or more, lanatoside C (Cedilanid), in a dosage of 0.2 to 0.4 mg., is given intravenously. It takes effect in about 20 minutes; often the rate falls abruptly to 80 per minute. During this waiting period the lungs are well ventilated. Quinidine sulfate, dosage 0.4 Gm. intravenously, is rarely used for frequent extrasystoles. The most effective way to take care of these is to reduce manipulation of the heart or to give it complete periods of rest or not to handle it at all.

Postoperative Care

The patient is conscious when the dressing is applied to the wound and when the intratracheal tube is removed. The patient is placed in semi-Fowler's position, given oxygen nasally, and kept in the recovery room for about five hours. Glucose solution is given intravenously, but the needle is removed after several hours. After return to his room, the patient sits up and dangles his legs or sits in a bedside chair. Sedation is kept to a minimum. Coughing and arm movements are encouraged. On the next day the patient stands on his feet for about 30 minutes, three times. The physiotherapist takes over for exercises the first day after operation and continues for one week. On the second day the tube is removed from the chest. Use of antibiotics and digitoxin is discontinued after one week. One, sometimes two, x-rays of the chest are taken after operation. Discharge from the hospital occurs on the 10th to the 14th day after operation.

The complications are few. In one patient the heart began to fibrillate and stopped beating four hours after operation. This occurred in the recovery room, which is near the operating room. One of us (C. S. B.) was operating on another patient when it occurred. He immediately left the operation, opened the chest while the patient was in the recovery room, pumped the heart for 35 minutes, and shocked the heart out of fibrillation; the patient is alive with no mental deficit and little or no anginal pain two years later. In several other patients fibrillation occurred, but the heart beat could not be restored. In these we tried unsuccessfully to clean out a coronary artery. Other complications were an embolus to an arm, and this embolus was successfully removed; mesenteric thrombosis occurred, and the artery was cleaned out, but it clotted again and the patient died. Complications have been few.

Early Observations After Operation.—The sedative effects of the surgical procedure are passed off by the second or third day. At this time when the patient is asked how he feels, he usually states that his chest hurts and points to the incision. When asked how his heart feels he usually states "It feels alright; I have not noticed that I have a heart; it feels free and looser; it isn't tight." How about pain? "I have not had any of the old heart pain; my arm feels better, and I feel warmer." This type of early report occurs in the majority of patients. Before discharge from the hospital the patient is allowed to try himself out on two or three flights of stairs. To the patient and to us doing this work, the reaction of the patient to exercise is most gratifying.

On discharge from the hospital the patient is told not to expect too much because his disease has not been cured, that after increased physical exertion he may have some pain, that he should not hesitate to take a glyceryl trinitrate pill for it, and that his improvement will continue over a period of several months.

Mortality.—Mortality depends to some extent on the type of patient selected for operation. If operation were applied only to patients in the terminal stages of this disease the mortality would be prohibitive. On the other hand, if it were applied only to patients with slight disease, the mortality would be zero or almost zero. Our policy is not to aim at zero mortality, because in achieving such a record patients who need help and who could be rehabilitated to a work-status would be denied operation. One-third of our patients have advanced disease as determined by examination of arteries and muscle at the time of operation. These patients are classified as salvage.

From Jan. 1, 1954, to Feb. 14, 1958, the Beck operation was done on 347 patients. These were consecutive operations done at University Hospitals and at Mount Sinai Hospital, Cleveland. During the period of hospitalization the total mortality was 21, or 6%. The total mortality after discharge from the hospital during a period of somewhat more than four years was 32, or 9.2%. Within this series were 100 consecutive operations with zero operative mortality, and in the subsequent series of 100 cases there were four patients who died, making the mortality 2% in 200 consecutive cases.

In the 110 salvage cases the hospital mortality was 11%, and the subsequent mortality was 15% for a total of 26%. In the 234 nonsalvage cases the hospital mortality was 3%, and the subsequent mortality during the four-year period was 7% for a total of 10%. There were three patients not classified. In the nonsalvage cases, the risk of operation is small and the life span appears to be excellent. In patients with coronary heart disease this record emphasizes the desirability of early operation. The death factor in the early stages of the disease is electric imbalance, and operation is especially designed for this factor.

Clinical Results

Relief of Pain.—Relief of pain is experienced within a few days after operation. Even at operation the heart is less irritable toward the end of the procedure than when it was first touched. A scratch on the skin to mark the incision becomes a band of red within a few moments. Similar changes are, no doubt, possible in the heart, and the heart is extremely responsive to any changes in blood supply.

A survey of clinical results was completed recently. In this series of 347 patients, 295 patients are now living. Each of these was contacted. Two hundred seventy-eight of these patients, 94%, received an excellent result (32%) or a good result (62%). The definition of an excellent result is applied to those who are completely or almost completely free of pain and have taken no medicaments since operation. The definition of a good result is applied to those patients who are improved after operation but who have an occasional pain and who take significantly less medicaments than before operation. The results in the 73 living patients classified as salvage are almost as good as those obtained in the other group. The percentage of excellent results, 22%, is less, but the percentage who received improvement was as high or even higher than in the other group. Because of this we believe the restrictions for acceptance of patients for operation should be as broad as possible, even though it involves increased mortality.

The patients herein analyzed have had the experiences of medical treatment first and surgical operation later. These patients, therefore, can compare the relative merits of medical and surgical therapy. The superiority of surgical versus medical treatment is in about the same proportion as measured in the laboratory or about five to one in favor of surgical operation. Furthermore, the surgical result is permanent while the drug-effect is transient. Many of the patients were disappointed with medical therapy and were critical of their professional care, in that operation had been delayed or that the patient had even been advised not to have the operation done. This reaction by the patients was intensified by the knowledge that medicaments fail to produce intercoronaries and that all they were receiving from the medication was transient relief of pain. To these patients this is not enough.

Increased Capacity for Work.—Almost all patients are able to go back to their previous jobs or are able to do some kind of gainful work. Some of the patients were completely incapacitated for work before operation, and others were not so incapacitated. With many a patient the anatomy in the heart is good and the anginal pain is comparable to an incapacitating toothache and the result of operation is comparable to that after extraction of the tooth. To be freed from incapaciting anginal pain is scarcely a figment of the patient's mind.

Cold Feet Before Operation; Warm Feet After Operation.—Many patients stated that their feet were warmer after operation. A study of foot temperatures was carried out.[4] Twenty-three patients were studied who had cold feet before operation. In 21 of these the temperatures after operation rose 4 to 5 C. The greatest rise was 10 C in one patient and 8 C in each of two others. If the temperatures were normal before operation, they remained normal after operation. What is the significance of warming of cold feet? First, this is an objective measurement which must be accepted as fact. Physiologically it means that the circulation to the feet is improved by operation on the heart; more blood has reached the feet. The mechanism is not known, but presumably it is by release of spasm.

Many patients state that the entire body is warmer. Some of the patients stated that their memory is improved and that they can comprehend conversation better. Releasing of cerebral spasm is not to be dismissed as an impossibility.

Absent Radial Pulse Before Operation and Return After Operation.—The radial pulse in the left arm disappeared when a patient had an occlusion of a coronary artery. Blood pressure could not be obtained in this arm, and the pulse was absent for one year when operation was done on the heart. Two days after operation it was noticed that the pulse was present and the blood pressure in the left arm was the same as in the right arm. The obvious explanation of this is that the disease produced arterial spasm of a large artery elsewhere in the body and that this spasm was released by operation on the heart. In terms of physiology it is significant, first, that this relationship existed and, second, that the surgical operation was effective in releasing it.

Irregularities of Heart Beat Before Operation; Disappearance After Operation.—In 20 patients operated on, chronic arrhythmia was the most prominent and important symptom before operation. These arrhythmias in most of these patients were distressing and alarming. In 17 patients the arrhythmias either completely disappeared or they diminished in frequency and severity after operation.[5] This is presented as objective evidence of benefit from operation.

Improvement in Ballistocardiogram After Operation.—Ballistocardiograms were done on 17 consecutive patients operated on. In 13 of these the record was abnormal; in 3 it was normal. Significant improvement in the record occurred after operation in 11 of the 13 patients who showed abnormal records before operation.[6] in two, the record did not change. The improvement in the ballistocardiogram indicates improved contractility of the myocardium. This study is presented as objective (not subjective) evidence of benefit from operation.

Summary and Conclusions

Blood supply to ischemic muscle is the primary consideration in the physiology and treatment of coronary heart disease. The relative effectiveness of glyceryl trinitrate and of surgical operation has been studied. The problem of treatment is selection of the most effective method for the three disease factors. These are electric imbalance, inflow reduction, and muscle destruction. The first of these yields to surgical treatment.

Results, including mortality, subjective improvement, and objective measurements, were studied in 347 consecutive patients. The fact that cold feet be'ore operation become warm after operation indicates improved circulation in far away parts of the body. The physiology involved here deserves more han passing consideration. This objectivity together with the clinical results (plus a firm foundation rom the laboratory) should help to prove that the peration is nothing less than an effective and beneficial procedure.

YOUR MALPRACTICE INSURANCE CONTRACT

Howard Hassard, LL.B., San Francisco

Professional liability insurance contracts are not all the same. Individual contracts must be studied for possible gaps in coverage. The limitations and exclusions they contain are not a criticism of the insurance industry, for they determine whether an insurance company can stay in business. The physician should understand the insuring clause, monetary limits, exclusions, practice limitations, territorial limitations, settlement restrictions, the cancellation clause, and the extent of his duty to cooperate with the insurer. The basic reason for the need of cooperation is that the insurance carrier assumes a substantial monetary risk and, in return for it, is entitled not only to a premium but also to full and honest assistance from the insured physician. The gravest error is to purchase on the basis of price alone. Physicians should examine their current professional liability policies with these facts in mind.

Professional liability insurance does not cover all possible risks that are inherent in the practice of medicine. Even with high limits of coverage, medical society endorsement, or the assistance of a skilled broker, there may still be gaps in your contract. Accordingly, you must be aware of the major points to check before you buy.

Examination of Insurance Contract

The Insurance Carrier.—Know the other party to the contract: the insurance carrier. Some companies have a well-deserved reputation for liberal handling and not resorting to loopholes; others are noted for strict interpretation and resort to the fine print.

Seek companies that are well established and that have adequate reserves and unassigned surplus. A company with inadequate reserves or surplus may be inclined to seek loopholes if it faces a heavy loss and leave you, the physician, to face the plaintiff's lawyer alone and unprotected.

The insurance company should be subject to the laws of the state where you practice and subject to insurance department rules and regulations. In the

---

Read in the Session on Medical Professional Liability before the Section on Miscellaneous Topics at the 107th Annual Meeting of the American Medical Association, San Francisco, June 24, 1958.

event of a suit over the policy provisions or activities of the company, the state insurance department can be of material assistance without cost to the insured.

It is essential in the field of malpractice liability, because of latent liabilities, that the company not only has financial stability but has been in business long enough so that it can be reasonably expected to continue in business in the foreseeable future.

Differentiation of Terms.—Know what your contract with the insurance company contains and does not contain. Know the differences between company, broker, and agent:

The Company: A company or insurance carrier is the entity, usually a corporation, which is financially obligated under the insurance contract to carry out the provisions of the policy and to assume the defense and expense of any claims brought against the assured under the policy.

The Broker: A broker is one who is licensed to transact the business of insurance and who represents the buyer. He may place his business with any company, and in so doing he remains the agent of the buyer. You may look only to your broker and no one else in the event he fails to remit your premium to the company, secures improper coverage, or carelessly handles your needs.

The Agent: An agent is one who is licensed by an insurance company to transact the business of insurance. He represents the company which licenses him, and he binds that company by agency. In this instance, responsibility is in both the agent and the insurance company. A person may be both a broker and an agent, but generally he is one or the other.

The Underwriter: Another term frequently used is "underwriter." Legally, this means an insurer or company, but some brokers adopt the term as part of a trade name. This practice is confusing, and one must be alert to the fact that underwriter may only signify a broker.

What Malpractice Policies Contain

You should know what is in your policy and how it works. Malpractice policies contain these subjects: (1) insuring clause, (2) monetary limits, (3) exclusions, (4) practice limitations, (5) territorial limitations, (6) settlement restrictions, (7) cancellation clause, and (8) provision for duty to cooperate with the insurer at all times.

The Insuring Clause.—The insuring clause in the contract defines types of claims covered. There is no uniformity in this field—unlike, for example, fire and life insurance. The usual insuring clause, which reads "injury arising out of malpractice, error, or mistake in rendering or failing to render professional services," should be carefully analyzed. It may not cover assault, battery, breach of implied contract, libel and slander, and agreements guaranteeing the result of treatment, to specify some of the nonerror types of claim. You should read your contract carefully, with these questions in mind:

First, does your policy contain a provision to defend all claims and suits, including malicious prosecution, counterclaims and cross-complaints (which arise when suing to collect fees), and suits based on failure to act (omission), i. e., services you "should have rendered"?

Second, do you have coverage for personal restraint? This means false imprisonment (for instance, a claim may arise when helping a family cope with an acute psychiatric emergency).

Third, do you have coverage for undue familiarity? Take precautions; take your nurse on calls, and never examine alone if you have reason for suspicion.

Fourth, does your policy include coverage for assault and battery? Four per cent of all suits against physicians are not based on alleged malpractice but are predicated on a claim of assault and battery. Generally, such suits claim the surgeon operated without proper consent or went beyond consent given.

Fifth, what about implied contracts? You may be sued for breach of contract if your patient interprets your prognosis as a guarantee he will get well. Say nothing that will be interpreted as a promise to cure. Suing for breach of contract has become popular of late among plaintiffs' lawyers. It gets around necessity for an expert witness, but, also, it gets around your insurance unless your policy expressly covers contract claims.

Sixth, does your policy cover you in case of charge of libel or slander? A patient may claim violation of your duty to remain silent. The California Medical Practice Act states that willful betrayal of a professional secret is ground for revocation of license; it can also be the basis for a slander suit. Say or write nothing that will violate the privilege.

Seventh, is premise liability coverage included? This is important if you are the owner or lessee of premises. Sometimes it is difficult to determine whether a suit is for alleged malpractice or for premise liability—as when a patient falls in a treatment room. Use the same company for malpractice and premise liability. Split liability can involve a conflict between carriers and shifting of responsibility, e. g., a patient under narcotics slips on tile in waiting room—which policy covers it?

Before leaving the subject of scope of coverage, I cannot resist recounting an unusual happening. A doctor, while performing an orthopedic procedure in a hospital, caused the instrument to slip, badly injuring his physician assistant. The question was what insurance would protect the doctor from a claim or suit by the assisting physician?

His malpractice insurance actually did not apply, because this accident was not covered under the insuring clause which only covered injuries to patients while rendering professional services. His comprehensive personal liability did not apply, as professional services or business activities were excluded. His premise liability policy did not apply, as it was unrelated to the insured premises (i. e., his office). The hospital insurance did not apply, for it did not involve defective equipment. The doctor was completely dependent on a superliberal interpretation of his malpractice contract to cover the claim.

Monetary Limits.—How much insurance coverage do you have? Are your total limits measured by occurrence of accident or aggregate?

Are legal expenses included? With today's verdicts, \$100,000-per-\$300,000 coverage does not go very far. In California there have been several jury verdicts over \$200,000 and at least one settlement before trial in excess of \$250,000.

Exclusions.—Read your policy to be on guard as to what is not covered. The exclusions are usually plainly and unequivocally stated.

Are other people in your office covered? These include nurses, assistants, employees, and substitutes or *locum tenens*. I know it is not nice to mention it, but if a physician employs a "ghost" surgeon he may be uninsured, because some policies require the specific consent of the patient to the operator as well as to the operation. Also, are your partners insured? Suppose you are individually insured, and your partner is being sued and he dies; you are responsible for his acts as partner. Are you covered? It is wise to have partners covered in the same company and as partners, as well as individually.

Some of the routine exclusions are as follows: First, intoxication and drugs, the exclusion for which usually reads, "shall not pay . . . in suits based on services rendered while under the influence of intoxicants or drugs."

If you leave a cocktail party to answer an emergency call, are you covered? If you took barbiturates at bedtime and answered an emergency call, are you covered?

If your contract excludes acts or omissions "while under the influence of drugs or alcohol," strictly speaking you are not covered for damages if an "under the influence" charge is made and can be proved. "Under the influence" or "drunk" are not well-defined phrases. Different courts define both terms in different ways. "Under the influence" is a relative term embracing various degrees of intoxication and mental obscuration. Here are a few sample definitions:

> This condition presents various degrees of intensity, ranging from a simple exhilaration to a state of utter unconsciousness and insensibility. (*Paris v. Robinson,* 140 S. W. 434)
>
> The condition of a man whose mind is affected by the immediate use of intoxicating drinks. . . . Under the influence of intoxicating liquor to such an extent as to have lost the normal control of one's body and mental faculties, and, commonly, to evince a disposition to violence, quarrelsomeness and bestiality. (*Zee v. Gary,* 189 So. 34)
>
> When one's brain is so far affected by potations of liquor that his intelligence, sense perception, judgment, continuity of thought, or of ideas, speech, and coordination of volition with muscular action are impaired or are not under normal control. (*Wilson v. Inter-Ocean Cas. Co.,* 188 S. E. 102)

Second, unlawful or criminal acts are invariably excluded. Is this limited to acts you know to be wrong? What about innocent acts, or what if you are forced to take unlawful action by an emergency or physical compulsion of another?

What is an unlawful act? Is it any infraction, no matter how minor, or must it be a felony or a serious misdemeanor? Is the word "unlawful" synonymous with "criminal"?

How directly must the unlawful act be connected? An illegal abortion is clearly not covered, but how about plastic surgery on a criminal? Or, what if you employ an unlicensed person in your office? In one California case, years ago, the insurer denied liability in a case against a partnership of radiologists because they had employed a well-trained radiologist from Canada who was not yet licensed in California. The insurer said employment of unlicensed physicians is unlawful, we exclude unlawful acts, good bye.

Is all coverage lost by violation of this condition? Under one form of contract the physician loses both his defense costs and indemnity in the event a suit against him falls within the "unlawful acts" exclusion. Under another form of contract the insurance company must still defend the physician, even though unlawful acts are charged or found, but the physician is obligated to pay any judgment rendered against him.

It is essential that each physician know the effect of each and all of the exclusion clauses in his malpractice contract.

Practice Limitations.—There are two types of practice limitation found in malpractice insurance contracts. One type is an outright exclusion of certain procedures, e. g., fluoroscopy and anesthesia, unless a special added premium is paid; the other type is a classification of practice for determining a basic premium rate, i. e., general practice versus surgery.

Frequently, the application for insurance that must be signed in order to obtain a contract contains representations by the physician as to the scope and type of his practice. These representations may or may not be "warranties." If the application form becomes a part of the contract or uses language to the effect that the insurer may rely on the representations as warranties, it is possible that a mistake or omission by the physician in filling out the application form can result in a denial of liability by the insurer, if a claim arises. It is essential, therefore, that each physician carefully read and accurately answer the application, particularly those questions relating to the scope and type of practice, as well as questions relating to prior claims or suits.

The usual practice limitations found are anesthesiology, therapeutic radiology, and fluoroscopy. The usual basic premium rate differentials are between 100% nonsurgery, some surgery, and exclusively a surgical practice.

As long as the word "surgery" is understood, classification for rating purposes by the physician is not difficult. However, surgery may be defined differently in different insurance contracts. One contract, for example, defines both major surgery and minor surgery. Another contract classifies everything that involves puncturing, penetrating, or severing tissue as surgery.

Incidentally, the contract that classifies major surgery and minor surgery for rate purposes distinguishes between major and minor by listing specific procedures under each category. The physician must carefully read the entire list in order to be certain that he properly classifies himself.

Territorial Limitations.—Many malpractice insurance contracts exclude coverage while the insured is outside the United States and its territories. Some policies include Canada, but no other foreign country. If you travel abroad be sure and check your malpractice contract in advance, because even emergency treatment rendered outside the United States could result in a lawsuit for which you would be uninsured.

Settlement Restrictions.—Most professional liability insurance contracts provide that the insurance company may not settle a claim or suit without the consent of the insured physician. This is a most important provision for the protection of the physician. Inasmuch as professional liability claims involve professional reputations as well as money, it is of paramount interest to the insured physician that he have control over the disposition of a claim made against him. Some professional liability contracts omit this provision and allow the insurance carrier to settle claims without the consent of the physician. A few contracts contain a built-in booby trap; it is this:

The contract contains the usual provision that settlement may not be made without the consent of the insured physician, but then a sentence follows providing that, if the physician refuses to approve a settlement offer and the case is then tried and lost, the insurance coverage is automatically limited to the amount of the settlement offer. In other words, a physician may refuse to settle, but if he does so he acts at his own risk and automatically reduces the amount of his coverage to the amount of the tendered settlement.

Cancellation Clauses.—Practically all professional liability insurance contracts permit either party to cancel at any time; usually 10 or 30 days' written notice of intent to cancel is required. A few group programs have protection against wholesale cancellation by agreement with the group carrier; however, this is the exception rather than the rule. Most physicians in the United States are currently insured for professional liability under contracts that can be canceled in not more than 30 days.

Duty to Cooperate with Insurer.—The typical professional liability policy contains the following clause: "The insured shall cooperate with the company, and, on the company's request, shall attend hearings and trials and shall assist in effecting settlements, securing and giving evidence, obtaining the attendance of witnesses, and in the conduct of suits. . . . The insured shall not voluntarily make any payment, assume any obligation, or incur any expense at his own cost, without the consent of the company previously given in writing."

Various contracts will use variations of the foregoing language, but all in effect require the insured physician to cooperate with the insurer in the defense of any claim or suit.

Cooperation includes prompt notice to the insurance carrier whenever an incident occurs that could give rise to a liability claim; cooperation requires that the insured physician not undertake to handle the matter himself; and cooperation requires that the physician not "build" a claim in conjunction with his patient for the purpose of securing compensation from the insurance carrier. Such activity can result in the insurance carrier denying liability because of the physician's breach of the cooperation clause.

The basic reason for the contract provisions requiring that the physician cooperate with and assist his insurer is that the insurance carrier assumes a substantial monetary risk, and in return for this risk it is entitled not only to a premium but also to full and honest help and assistance from the insured physician.

Another facet of the cooperation clause is the usual contract provision that the insured physician shall neither admit liability nor attempt to make a settlement on his own account. It is most important to remember that in all liability insurance contracts the insured has no right to give away the insurer's money.

Comment

Professional liability insurance contracts are not all the same. They differ in many respects and are almost as individualistic as women's hats. It is never safe to purchase professional liability coverage without reading and understanding the contract, on the assumption that it will protect you no matter what happens. In fact, even the broadest professional liability policy contains exclusions and limitations. Have your policy provisions interpreted by a person experienced in professional liability insurance who can relate the insurance clauses to the practice of medicine. Few people in the insurance business or in the legal profession have had sufficient experience in the medical malpractice field to properly apply policy terms to a medical practice.

For example, assault and battery is generally interpreted as a physical assault, whereas in malpractice it is, in addition, interpreted to include failure to obtain a proper consent to a treatment or operation or failure to inform a patient of any change in the original scope of the surgery to be performed.

The gravest error is to purchase on the basis of price alone. When a physician is threatened with a professional liability suit, he desperately needs the aid and assistance of expert claims adjusters and counsel—to say nothing of the need to protect his property. The penny-wise pound-foolish purchaser who bought the cheapest contract and did not read it may discover when his need arises that he is not covered; or he may find that he is covered but has a contract that permits the insurance carrier to compromise or settle without his consent or that he has a contract with a five-day cancellation clause which is immediately exercised.

The fact that professional liability insurance contracts contain exclusions and limitations is not a criticism of the insurance industry. An insurance company to stay in business must at least break even; no business can survive for long if it pays out more than it takes in. The insurance business is highly competitive; the purchasers of insurance pick and choose; and when the buyers want price economies the insurance carriers have no choice—to stay in business they must compete price-wise, and to compete price-wise they must limit their liability. No one can change this basic law of economics.

Conclusions

I hope that this paper may stimulate those physicians who hear or read it to examine their current professional liability policies, and to determine—through inquiry to their carriers if necessary—the acts or omissions for which they are covered or not covered, and the limitations and other provisions that may take away coverage if the physician's behavior is contrary to the contractual commitment. It is better to know in advance than to find out after it is too late.

111 Sutter St. (4).

EXPERT WITNESS AND ADVISORY PANELS

Joseph F. Sadusk Jr., M.D., Oakland, Calif.

The difficulty involved in obtaining expert medical testimony from physicians in personal injury cases is well known. It is due not to his unwillingness to cooperate with the law but rather to the fact that he is cast into an atmosphere foreign to his training and philosophy. The physician is trained as a scientist to present medical data and conclusions in a narrative and factual manner and to elaborate on the pros and cons of the medical problem. Due to the adversary system of trial in the United States, this is not generally possible. Under such a system, the physician replies to a series of questions which, when put by an experienced trial attorney, may modify, twist, and distort the true medical story.

A milestone was reached in 1952 when the justices of the Supreme Court of the County of New York encouraged the local bar associations and medical societies to embark on a system for impartial medical testimony in personal injury cases.[1] The success of this project led to a permanent continuation of the procedure, and similar or identical plans will doubtless appear in other parts of the United States.

Except for an initial pilot plan pioneered by the Los Angeles County medical and bar associations several years ago, there has been little or no at-

It is difficult to obtain expert medical testimony from physicians in personal injury cases. This is not due to unwillingness to cooperate with the law but rather to the fact that the physician is cast into an atmosphere foreign to his training and philosophy. A plan has been formulated to make available a panel of physicians for consultation with attorneys of the local or neighboring bar associations for presuit expert opinion and, where suit is instituted, for testimony as an expert witness. The education of physicians to serve on these professional liability medical panels is considered of paramount importance. This is accomplished through a thorough indoctrination by a joint committee of the local medical and bar associations, with or without the assistance of special statewide indoctrination committees where such assistance is considered desirable and necessary by the local working units. The success of these panels will depend on the professional qualifications and impartiality of the panel physicians and the willingness and readiness of attorneys to accept a neutral and unbiased opinion.

Member, Committee on Medicolegal Problems, American Medical Association.

Read in the Session on Medical Professional Liability before the Section on Miscellaneous Topics at the 107th Annual Meeting of the American Medical Association, San Francisco, June 24, 1958.

tempt to solve the problems of expert medical advice and testimony in the field of medical malpractice, a small but nevertheless important segment of personal injury litigation. Here the natural disinclination for the physician to testify is compounded by the fact that he must advise and testify against a colleague—a fellow physician—whom he may see week in and week out. Such reluctance is natural and understandable. The law and organized medicine have long been aware of this problem, but it remained for the California Medical Association and the State Bar of California to simultaneously agree to investigate and confer on the solution of the availability of impartial medical expert witnesses in alleged medical malpractice cases.

As a result of the 1955 meeting of the Conference of California State Bar Delegates, a committee was appointed to study the problem of obtaining evidence in malpractice cases. Meetings were held with representatives of the California Medical Association to explore the situation, after which the Board of Governors of the California State Bar and the Council of the California Medical Association appointed comparable committees to meet in joint session to formulate a plan which would make available to attorneys the services of qualified physicians to advise on a case of alleged malpractice and, if suit were instituted, to testify as an expert witness. In September, 1957, these committees recommended to their respective parent organizations the plan presented here.[2]

The Plan

The purpose of the plan is to form a panel of physicians available for consultation with attorneys of the local or neighboring bar associations for presuit expert opinion and, where suit is instituted, for testimony as an expert witness. Such a panel would be used only for cases of alleged medical malpractice.

Selection of panels would be on an appointment basis by the medical societies within each territorial district, with approval of the panel by the board of directors of the applicable local county bar association.

Disqualification of a panel member would occur if he is treating or has ever treated or consulted on the plaintiff patient or if there is a relationship, business or otherwise, between the panel member and the defendant physician.

The panels would include members from general practice, from the following basic specialty areas of medical malpractice, and from such additional areas of specialty practice as shall be determined within each district: (1) medicine, (2) surgery, (3) obstetrics and gynecology, (4) pediatrics, (5) pathology, and (6) radiology.

Administration of a panel would be by a designated officer of the local county bar association, with names on file.

A panel member would be called by the complainant's request in writing to a physician on a panel list as submitted by the local bar association. The physician then notifies his county medical society and the local bar association in writing of the requested consultation, giving name of attorney, complainant, and physician complained against.

Education of a panel would be accomplished by a series of lectures from a joint committee of local medical and bar association members or by special statewide indoctrination committees.

For the consultation and examination, review of records, preparation of report, and testimony, the physician receives the reasonable value of his time in accordance with the prevailing fees in his community.

No reference may be made in court to the panel or medical or bar associations' participation therein. Judges are requested to adopt a rule forbidding counsel (on each side) to mention the status of the witness in relation to the panel.

A panel physician who consults with or examines a complainant may not, without the consent of the complainant, be examined in a civil action as to any information acquired from the complainant which was necessary to enable the physician to prescribe or act for the complainant, except as provided below.

A complainant may secure additional examinations or consultations from the panel list, but only if the complainant agrees in writing, with the preceding panelist consulted, that the latter may be examined in any civil action based on the complaints involved.

A complainant may secure an examination or consultation with a second member of the over-all panel without being required to waive the confidential nature of the first examination or consultation, providing the initial panelist selected reports in writing to the administrative officer of the local county bar association that the complaint is not within his area of practice or that a second examination or consultation is necessary or advisable for the stated cause.

The "Ground Rules" of the Plan

This plan was approved by the governing bodies of the parent organizations in September, 1957. The committees then met again to outline and to recommend certain "ground rules" to the individual medical societies and county bar associations of California, at which level the plan was to be implemented. Further, it was made clear that these working units were free to modify the plan to meet local conditions and attitudes and, indeed, the local county and bar units were free to accept or reject the entire concept of such panels. These basic "ground rules" were as follows:

Panel members are to be appointed by the county society, not selected from volunteers. Only those panel appointees who have attended the indoctrination lectures are eligible to serve. Present members of public service or malpractice committees of county societies are not eligible for service on the panel. Panel appointments are for one year only; a new panel is appointed each year, but the same physicians are eligible year after year. Panel members, as such, are available to complainants against doctors of medicine only. In each county, the panel should be representative of the practice of medicine in that area as to specialties and general practitioners. The financial arrangements between the complainant's attorney and the panel member are to be by agreement between them, although a fee scale may be established by the county medical society if it so desires. Fees are to be paid in advance unless otherwise agreed between the panel member and the attorney.

Specific Instructions for the Physician

The education of physicians to serve on these professional liability medical panels was considered of paramount importance, to be accomplished through a thorough indoctrination by a joint committee of the local medical and bar associations, with or without the assistance of special statewide indoctrination committees where such assistance is considered desirable and necessary by the local working units. Specific instructions are to be sent to each physician panel member with his obligations clearly outlined along the following lines.

Notification of State and County Bar and Medical Associations.—The physician will be instructed to immediately notify the respective organizations by completion of a special form in quintuplicate, of which he will retain one copy and mail the remaining four copies to the California Medical Association. This organization will assume the responsibility for distribution of the copies to the county bar and medical associations and to the California State Bar. This notification is considered necessary to insure the adherence of attorneys to the rule of the formulated plan which provides for written waivers by the complainant or his attorney when securing additional medical opinions from the panel. In addition, these reports will insure that the panel member's rights will be protected by the bar and medical associations. Further, analyses will be made as the years go along to evaluate and to improve the program.

Instructions for Thorough Study of All Medical Factors.—The necessity for a thorough and impartial review of the case before the physician expresses an opinion is to be emphasized to the physician, wherein he is to examine the patient, and to review all available evidence including hospital records, x-rays, laboratory reports, and other medical records and data which can reasonably be obtained before rendering a report.

Report of Opinion and Testimony.—The physician will be required to submit his report to the plaintiff's attorney in writing covering history of the injury, the patient's account for treatment and its results, findings on examination of the injured part or parts and notation of abnormalities, indications if another field of medicine outside the physician's field is involved, the extent of injuries and conclusions as to degree of disability, and, finally, an opinion as to whether or not the defendant doctor deviated from the legal requirement of "standard and accepted medical practice." It will be the physician's duty to testify in court as to his opinion if the case goes to trial.

Objective and Impartial Attitude.—The physician will be advised to not become an advocate for either side but rather to evaluate the facts objectively and render an impartial opinion.

Promptness in Rendering Reports.—The physician will be impressed by the fact that undue delay in reporting to the plaintiff's attorney may prejudice the interests of either or both the complainant and the doctor complained against.

Disqualification of Panel Physician.—The panel physician is to be disqualified if (1) he has treated or is treating the complaining patient or has been consulted by representatives of the physician, (2) there are personal or other relations with the patient which might prejudice the physician's opinion, (3) there is a business or a personal relationship between the panel physician and the defendant physician which would make it impossible to render an impartial opinion, (4) the medical problem is not within the field of practice of the panel physician, and (5) the nature of the case or other commitments would make it impossible for the physician to devote the time necessary for a full study of the case.

Comment

It is to be emphasized that this plan for a professional liability medical panel has not yet reached the working stage. These panels are presently being set up throughout the major population areas of California where agreed to by both local county medical and bar associations. Modifications and changes will doubtless be required as time goes along with experience gained by attorneys and physicians in the use of the panel.

The success of these panels will depend on the professional qualifications and impartiality of the panel physicians and the willingness and readiness of attorneys to accept a neutral and unbiased opinion. That organized medicine and the law has reached such an agreement speaks for the willingness of both parties to serve the administration of justice.

459 30th St. (9).

CLINICAL NOTES

ASYSTOLE COMPLICATING ACUTE MYOCARDIAL INFARCTION

SURVIVAL WITH THE AID OF A CARDIAC PACEMAKER AND INTRAVENOUS ADMINISTRATION OF ISOPROTERENOL

Sylvan D. Solarz, M.D., David M. Berkson, M.D.
and
Alfred Pick, M.D., Chicago

Since the development by Zoll[1] of an external cardiac pacemaker capable of producing effective ventricular contractions by transthoracic electric stimulation many cases of asystole have been successfully treated with the aid of this device alone or in combination with intravenous administration of isoproterenol (Isuprel) hydrochloride.[2] The majority of the reported cases have been those of chronic atrioventricular block with Stokes-Adams disease. Recently we had opportunity to apply this regimen to a patient in whom an advanced second degree atrioventricular block with Stokes-Adams attacks developed acutely in the course of a myocardial infarct. (The term "advanced second degree atrioventricular block" is applied to cases in which several successively dropped beats initiate atrioventricular nodal escape and dissociation with or without ventricular captures.[3]) To our knowledge this is the first such case with survival treated in this manner. Continuous monitoring of the rapidly changing cardiac mechanism in conjunction with automatic release of the pacemaker when needed permitted prompt adjustments of the therapy according to instantaneous needs and an immediate evaluation of the effect each new procedure had on the cardiac rhythm. We used a unit consisting of an external cardiac pacemaker, a cardiac monitor with both visual and auditory signals of each ventricular beat, and a cardioscope with continuous display of an electrocardiographic tracing. After a predetermined asystolic period the pacemaker automatically goes into action, and an alarm is sounded. External electric impulses continue at a preselected rate and strength until the machine is turned off manually. This type of action serves to bring instant attention to the patient and to shorten the period of asystole.

Report of a Case

A 58-year-old female was admitted to Michael Reese Hospital on May 8, 1958, with the complaint of severe substernal pain. The patient had been under the care of one of us (S.D.S.) for five years because of coronary heart disease with anginal syndrome and congestive heart failure. She had been well maintained on therapy with digoxin (Lanoxin), chlorothiazide (Diuril), and glyceryl trinitrate. Previous electrocardiograms (fig. 1, *1953*) were relatively stable over the years and showed a first-degree atrioventricular and a right bundle-branch system block without evidence of myocardial infarction. The evening prior to admission the patient experienced substernal pain relieved by glyceryl trinitrate; however, later that night she was awakened from her sleep by severe chest pain requiring narcotics for relief.

On admission the pertinent physical findings were as follows: pulse 84 beats per minute and regular; blood pressure 140/70 mm. Hg bilaterally; thyroid gland slightly enlarged to palpation; the lungs clear; the heart size normal; the second aortic sound of normal intensity and louder than the second pulmonic sound; a grade 1 systolic murmur heard over the base of the heart; the liver not palpable and no signs of congestion.

Admission laboratory data included the following findings: hemoglobin level 13.4 Gm.; white blood cell count, 21,300 per cubic millimeter, with 85% polymorphonuclear cells, 11% lymphocytes, and 4% monocytes; sedimentation rate, 17 mm. per hour (Wintrobe); fasting blood sugar level, 168 mg.%; serum urea nitrogen level, 28 mg.%. The serum transaminase on May 8 was 24 units, and on May 9 it had risen to 73 units. The electrocardiogram (fig. 1, *5-8-58*) revealed, as previously, sinus rhythm with first-degree atrioventricular and right bundle-branch system block and, in addition, contour changes characteristic of acute posterior wall infarction. Initial therapy included bed rest, oxygen tent, anticoagulation with heparin and warfarin (Coumadin), and digoxin.

The patient did well for the first 24 hours. On May 9 an intermittent pulsus bigeminus was noted, and another electrocardiogram was taken. This showed sinus rhythm with incomplete atrioventricular dissociation due to a second-degree atrioventricular block with repetitive nodal escapes (fig. 2, 5-9) and further contour changes suggesting extension of the infarction to the lateral wall. The average ventricular rate was 60 per minute, and the blood pressure was unchanged. The patient remained in good clinical condition, and on the following day the heart rate was regular. On May 11 a pericardial friction rub was noted, and shortly thereafter the blood pressure fell precipitously, moist rales and hepatomegaly developed, and the clinical condition deteriorated rapidly. An intravenous-infusion of arterenol, 2 ampuls (16 mg.) in 1,000 cc. of 5% dextrose in water, was started immediately, and the patient received additional digitalis and a mercurial diuretic. The blood pressure promptly rose to satisfactory levels. An electrocardiogram (fig. 2,

---

From the Department of Medicine and the Cardiovascular Department of the Medical Research Institute, Michael Reese Hospital.

5-11) revealed irregularity and marked slowing of the ventricular rate to an average of 35 per minute due to a more advanced atrioventricular block with a complex mechanism[4] and signs of continued extension of the infarction. On May 12, because of a persistent slow ventricular rate, isoproterenol therapy, 10 mg. sublingually every four hours, was started. In spite of this there were several momentary lapses of consciousness, and the isoproterenol dosage was increased to 15 mg. On this medication the ventricular rate rose to 50 and became almost regular. An electrocardiogram (fig. 2, 5-12) showed sinus rhythm with a 2:1 atrioventricular block, alternating with periods of atrioventricular dissociation during which an accelerated ventricular pacemaker operated at about half the sinus rate. However, on the morning of May 13, an episode of ventricular asystole with convulsions and cyanosis occurred, and the patient appeared moribund. After vigorous pounding of the precordium the heart resumed beating. Isoproterenol, 0.2 mg., was given intramuscularly immediately, and the automatic external pacemaker was attached to the patient with the release time set at three seconds of asystole. The isoproterenol injection was repeated within the next hour but failed to prevent frequent periods of ventricular standstill. Each asystole brought the automatic pacemaker into action, with prompt restoration of spontaneous heart beats. A constant intravenous drip of isoproterenol was then begun, with 2 mg. per 500 cc. of 5% dextrose in water at an initial rate of 15-20 drops per minute corresponding to approximately 4 mcg. per minute.[2] After several periods of asystole leading to pacemaker discharge, it was found that 60 volts was adequate to produce ventricular contractions. Electrocardiograms between asystolic periods (fig. 3, *upper strip*) showed an irregular ventricular rate because of atrioventricular conduction ratios varying between 2:1 and 5:1, with ventricular escapes terminating those pauses which were not long enough to bring the external pacemaker into action. One of the longer ventricular pauses, with nine successively blocked P waves, leading to automatic discharge of the pacemaker and subsequent resumption of the original mechanism, is illustrated in the lower strip of figure 3.

From May 13 until the afternoon of May 15 the patient was kept on the regimen of treatment with intravenously given isoproterenol with the pacemaker constantly attached to the chest. During this period the predominant rhythm was a second-degree atrioventricular block with varying atrioventricular ratios. As the rate of the infusion was slowed, ventricular pauses became longer and caused discharge of the pacemaker. As the infusion rate was increased, shorter ventricular pauses were terminated by nodal or ventricular escapes, but in addition several brief paroxysms of auricular fibrillation and of ventricular tachycardia were observed on the cardioscope early on May 13 (fig. 2, *5-13*). Late that evening it was noted that the ventricular rate was slowing and numerous episodes of asystole occurred requiring pacemaker stimulation. It was necessary to increase the voltage and the number of successive shocks to overcome the periods of ventricular standstill. Increase in the rate of flow of isoproterenol failed to prevent ventricular pauses, but bizarre ventricular complexes of variable contour appeared, progressively increasing in frequency, and eventually a continuous ventricular tachycardia developed. After five minutes of this rhythm the patient appeared moribund. At this point it was decided to replace the isoproterenol infusion by procainamide (Pronestyl) hydrochloride in an attempt to convert the rhythm; 50 mg. was given cautiously. This caused slowing of the ventricular rate and reappearance of a few supraventricular beats. The administration of an additional 75 mg. led to a ventricular standstill. Repeated shocking by the external pacemaker caused resumption of the original supraventricular rhythm, and the isoproterenol infusion was restarted at a reduced rate of flow. Several minutes later, paroxysmal ventricular tachycardia again appeared. It was stopped by another 100 mg. of procainamide which was followed by protracted ventricular arrest and then restitution of intrinsic ventricular activity by external electric stimulation.

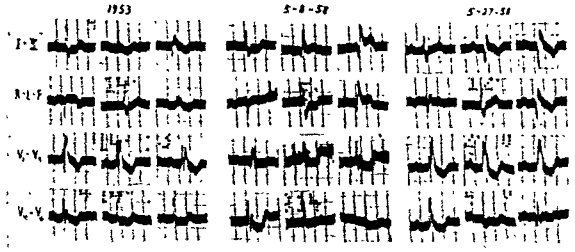

Fig. 1.—Three 12-lead electrocardiograms showing development (*1958*) of characteristic features of posterolateral wall infarction on top of a preexistent right bundle-branch system block (*1953*).

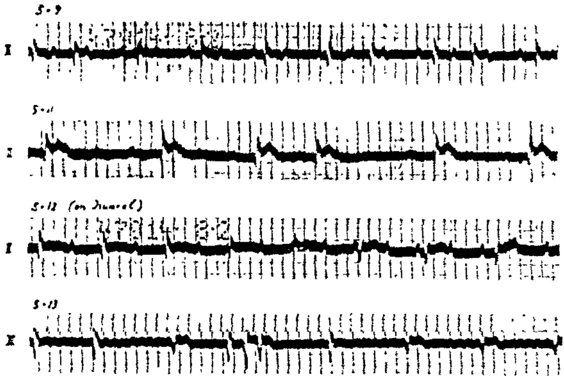

Fig. 2.—Electrocardiograms representative of variety of mechanisms encountered: Intermittent ventricular bigeminy as result of second-degree atrioventricular block with nodal escapes (*5-9*). Marked slowing of ventricular rate as result of more advanced atrioventricular block (*5-11*). Consequent to isoproterenol (Isuprel) medication, 2:1 atrioventricular conduction changing to atrioventricular dissociation with accelerated ventricular pacemaker (*5-12*). Paroxysm of auricular fibrillation with complete atrioventricular dissociation, alternating nodal and ventricular pacemakers, and short burst of ventricular tachycardia (*5-13*).

Because of this difficulty in controlling the rhythm, the concentration of isoproterenol was changed to 2 mg. per 750 cc. of 5% dextrose in water. In addition, on May 14, the arterenol infusion was discontinued. Throughout this day and thereafter the blood pressure remained constant. There were several episodes of asystole promptly terminated by the external pacemaker, and in the afternoon the rhythm became stabilized with second-degree atrioventricular block and spontaneous nodal or ventricular escapes. On the afternoon of May 15, the atrial action changed from sinus rhythm to fibrillation but the average ventricular rate remained 40. Slowing or speeding up of the isoproterenol infusion altered neither the atrial mechanism nor the ventricular rate. It was decided to stop the infusion to determine whether the ventricular rate would be maintained spontaneously. At first ectopic ventricular beats increased in frequency, and after 15 minutes asystole occurred long enough to cause discharge of the external pacemaker. Immediately after this, the auricular fibrillation reverted to sinus rhythm with second-degree atrioventricular block and a constant ventricular rate of 40. This was the last episode of asystole requiring external stimulation. On May 16 the atrioventricular block varied between first and second degree, and from May 17 on first-degree atrioventricular block became permanent (fig. 1, 5-27-58). The remainder of the hospital course was uneventful, signs of congestive heart failure gradually disappeared, and the patient was discharged on June 29, 1958. At the time of writing (August, 1958) she is following the usual course of recovery from a myocardial infarction of this severity.

Comment

The prognosis of advanced atrioventricular block complicating recent myocardial infarction has recently been reviewed by Cohen, Doctor, and one of us.[5] They found the over-all immediate (two-month) mortality in a series of 68 cases to be 47%, the death rate increasing with the severity of the block. Posterior wall infarcts accounted for 75% and carried an immediate mortality of 37%, whereas in anterior wall infarcts 75% of patients died. In 32 of 36 surviving cases, atrioventricular block was transient. The long-term prognosis of those surviving the first two months was not affected by the temporary conduction disturbance. Therefore, it appears that if a patient survives the initial complication of atrioventricular block his chances for long-term survival are as good as those of one with an uncomplicated myocardial infarction. From an anatomic viewpoint it would appear that patients with a transient block have ischemia or edema involving the conduction system whereas actual necrosis of these tissues is present in cases with permanent conduction defects. From the clinical standpoint one cannot distinguish between these two possibilities during the acute episode, the time when adequate therapy is of the utmost importance. It is in line with this that recently the successful use of adrenal steroids in cases of acute myocardial infarction with Stokes-Adams attacks has been reported.[6]

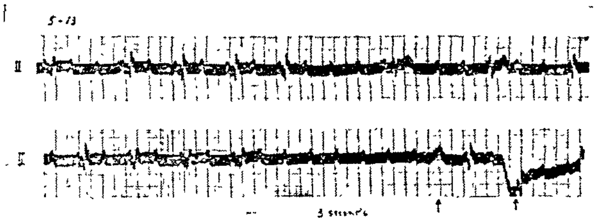

Fig. 3.—Consecutive portions of long record showing termination of ventricular pause by spontaneous ventricular escape (*upper strip*) and longer pause terminated by two automatic discharges of external pacemaker (*arrows*) initiating intrinsic ventricular impulse formation (*lower strip*).

While it is realized that each case of this nature requires individual measures which might not be applicable to others, in our case it is believed that the recovery is to be attributed not to a single agent or medication but rather to the awareness of impending attacks of asystole, to the proper preparations for handling such an event, and to the alertness of the members of the house staff assigned to this case.

The appearance of a bigeminal rhythm on auscultation early in the course of the patient's illness first brought to mind the possibility of second-degree atrioventricular block with 3:2 conduction. It has been our experience that bigeminy occurring in the course of acute posterior wall infarction is more often due to this latter mechanism than to ectopic impulse formation.[3] The electrocardiographic confirmation of the atrioventricular conduction disturbance alerted us to the possibility of its progression to Stokes-Adams attacks, although there was no clinical evidence of this at that time. As the degree of block increased isoproterenol medication was started sublingually, and the external pacemaker was kept nearby, ready for immediate use.

In order to maintain spontaneous intrinsic ventricular activity we had the choice of three sympathomimetic drugs: arterenol, epinephrine, and isoproterenol. At the time of the first syncope, the patient had been receiving arterenol intravenously constantly for about 48 hours and at that time was unable to maintain her blood pressure without it. The fact that such attacks occurred while the patient was receiving this drug is in keeping with its known pharmacological effects which do not include enhancement of nodal or ventricular pacemaker action. With regard to the two other agents, it has been found by Zoll and his co-workers[2] in comparative studies that, in patients with high blood pressure, isoproterenol might be preferable to epinephrine since it has no vasopressor action. On the other hand, epinephrine is the drug of choice when the pressure is normal or low. Furthermore, they state that epinephrine should be used in patients who, prior to the attacks, had functioning atrioventricular conduction "since it is a much less potent accelerator of the sinoatrial pacemaker than is isoproterenol and there is, accordingly, less risk of a rapid ventricular rate should atrioventricular conduction return." In our patient, however, the blood pressure had to be maintained artificially and it was felt that this should be done independently of the attempt to control ventricular activity. We were aware of the fact that the amount of the drug determining the ventricular rate might have to be varied from moment to moment and thus new problems might arise should control of blood pressure and ventricular activity depend on the same medication. For this reason isoproterenol and arterenol were used simultaneously.

After the first convulsion, the isoproterenol medication was changed from sublingual to intramuscular administration and the automatic external pacemaker was attached to the patient. This arrangement prevented the occurrence of further seizures, but it soon also revealed that isoproterenol per se was inadequate to prevent protracted periods of asystole, even after its administration by continuous intravenous drip. On the other hand, the continuous infusion of isoproterenol probably was responsible for the prompt resumption of spontaneous ventricular activity after one or two external electric shocks (fig. 3, *lower strip*), as was consistently noted on the cardioscope. The external pacemaker functioned as a stimulator of intrinsic mechanisms rather than as a substitute for spontaneous ventricular activity.

Therapeutic effects of isoproterenol consisted in stimulation of impulse formations in supraventricular and ventricular centers as well as in improvement of conductivity of the atrioventricular junction (fig. 2, *5-12*). This twofold action of the drug has been pointed out previously by us [7] as well as by others.[8] Toxic effects, on the other hand, caused by too rapid infusion consisted in undue acceleration of ventricular impulse formation culminating in almost fatal attacks of ventricular paroxysmal tachycardia which required procainamide medication. Whether or not the paroxysms of auricular fibrillation are to be ascribed to the isoproterenol medication is unanswered. Of considerable theoretical interest is the abrupt termination of auricular fibrillation on one occasion (May 15) by external electric stimulation.

The initial recommended concentration of isoproterenol for intravenous infusion (4 mcg. per cubic centimeter) [2] was found to provide too small a margin between therapeutic and toxic levels. This has also been our experience in other cases of patients with Stokes-Adams disease treated by isoproterenol in this hospital. More dilute solutions, for instance 3 mcg. per cubic centimeters, proved easier to handle and seemed to enhance the safety margin, although it still was difficult to regulate the dose of the medication. Nevertheless, the rapid disappearance of the effects of the diluted drug seems to reduce the dangers of this mode of administration provided constant observation is maintained. The latter is greatly aided by the continuous use of a cardioscope, which was an integral part of the procedure used in this case.

Summary and Conclusions

Survival of a patient with recent posterior wall infarction complicated by frequent attacks of ventricular asystole, as a consequence of a progressively advancing atrioventricular block, is attributed to the prompt and systematic use of an intravenous infusion of isoproterenol in combination with an automatic external pacemaker.

Success or failure of treatment of such cases largely depends on early recognition of impending syncope, on adequate preparations for handling of such an event, and on continuous monitoring of therapeutic measures by a cardioscope. The earliest clinical sign of impending asystole may be the development of a bigeminal pulse.

Recent myocardial infarction complicated by asystole may require the simultaneous use of two sympathomimetic agents: arterenol to maintain the blood pressure and isoproterenol to insure an adequate rate of ventricular contraction. Isoproterenol given as an intravenous infusion is not a harmless drug, and its overdosage may lead to dangerous, rapid ectopic rhythms of ventricular origin. The proper dose may vary from case to case and from moment to moment and requires adjustments under close and continuous observation on a cardioscope.

2011 E. 75th St., (49) (Dr. Solarz).

The external cardiac pacemaker unit used in this study was Electrodyne model PM65, manufactured by the Electrodyne Co., Norwood, Mass.

This study was supported in part by the Hibse Heart Fund for Cardiovascular Research and the Michael Reese Research Foundation.

CHLOROTHIAZIDE (DIURIL) AS A HYPERURICACIDEMIC AGENT

Benjamin G. Oren, M.D., Maurice Rich, M.D.
and
Martin S. Belle, M.D., Miami, Fla.

Chlorothiazide (Diuril) has been recently introduced into therapeutics, first, as an effective nonmercurial diuretic[1] and, more recently, as a potentiating hypotensive agent in the treatment of essential hypertension.[2] It apparently has proved to be quite effective in these actions but has a tendency to cause excessive excretion of sodium, potassium, and chloride.[3]

Recently, we noted that in some patients unexplained joint pains could occur, especially in the feet, during the use of this drug. Investigations show no organic cause for this symptom, but the uric acid levels in the blood were found to be elevated. Further investigation of a number of patients receiving this drug confirmed this observation, though joint and foot pain was by no means a uniform symptom. Indeed, some of the highest uric acid levels were associated with no joint pain whatever.

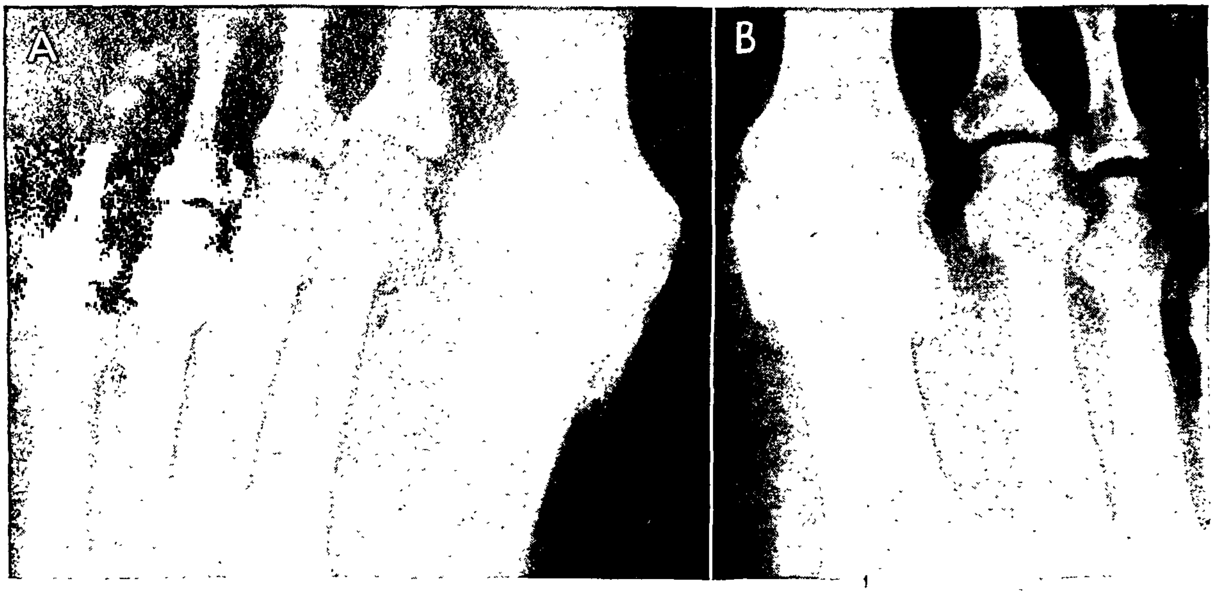
Two significant cases are reported below.

Report of Cases

Case 1.—A 44-year-old man had been under treatment for essential hypertension for three years, at first with Rauwolfia, subsequently with reserpine (Serpasil). He had suffered a coronary thrombosis two and one-half years ago. It was necessary for him to take 3 mg. of reserpine or its equivalent in order to attain an adequate normotensive effect. However, this large amount of drug resulted in considerable depression and an annoying sluggishness which made it difficult for the patient to continue with his therapy. Accordingly, one year ago associated therapy with chlorothiazide was begun, with smaller doses of reserpine. He was given 500 mg. of chlorothiazide twice daily with 0.25 mg. of reserpine twice daily. This resulted in an adequate control of blood pressure and a return of his mood to normal.

Within three months after institution of this therapy, the patient began to note unusual fatigue and especially pain in the feet on walking and at rest. This was a generalized aching discomfort in both feet. Various attempts to relieve the pain were instituted, including contrast baths, strapping, and various types of shoes, all without much benefit. X-rays showed no evidence of arthritis, tophi, or other organic bone or joint disease. The blood uric acid level was 6.8 mg. % (normal 3 to 5 mg. %). A few days thereafter the chlorothiazide therapy was discontinued, and another uric acid determination 10 days after cessation of the therapy was 4.1 mg. %. The foot pains had disappeared a few days after the discontinuation of chlorothiazide therapy.

Because of the need to control the hypertension, chlorothiazide therapy was again started on Feb. 1, 1958. Within two weeks the aching in the feet had recurred. A blood uric acid determination on June 2, 1958, was 6.6 mg. %. On June 5, chlorothiazide therapy was discontinued. Another determination of uric acid level was made on June 13, at which time it had returned to the normal value of 4.3 mg. %. Again the foot pains had disappeared.



Roentgenograms of both feet in case 2. Note, A, destruction of metatarsophalangeal joint space in right foot.

Clinical Associate Professor of Medicine (Dr. Oren) and Clinical Assistant Professor of Medicine (Drs. Rich and Belle), University of Miami School of Medicine.

Case 2.—A 46-year-old man was seen on May 6, 1954, with a history of unexplained hematemesis and melena requiring transfusions in 1950 and another episode of milder hematemesis in April, 1954. He seemed to be in good general physical condition. His blood pressure was 160/110 mm. Hg, and he was somewhat overweight. Gastrointestinal studies showed a minimal deformity of the duodenal bulb, and it was felt that previous episodes of hemorrhage had been from duodenal ulcer. The patient's blood pressure dropped to 110/90 mm. Hg on treatment with Rauwolfia. He got along well on medical therapy, but his blood pressure rose to 170/115 mm. Hg as he discontinued use of medicaments.

On Jan. 16, 1958, he was started on chlorothiazide therapy, 500 mg. twice daily, and reserpine, 0.25 mg. twice daily. The blood pressure thereupon promptly returned to 130/80 mm. Hg, and his weight dropped during the next six months from 197.5 to 166 lb. (89.6 to 75.3 kg.). He felt unusually well except that he began to note increasing pain in the right great toe with prominence at the base of the distal phalanx of the right metatarsal. When seen on Sept. 11, 1958, this had the appearance of gout; the joint was tender and swollen but not hot. On questioning, the patient recalled that he had been told several years previously that he had slight arthritis in the right great toe with small "punched-out areas" appearing on x-ray. Roentgenograms were taken showing destruction of the base of the metatarsophalangeal joint of the right great toe with osteophyte formation (see figure). It was felt that these changes were the result of gouty arthritis. The blood uric acid level was 6.5 mg. %. Chlorothiazide therapy was discontinued, and 12 days later the uric acid level had dropped to 5.4 mg. The pain, swelling, and tenderness in the joint had disappeared, and the patient was asymptomatic. The blood pressure remained at 120/80 mm. Hg.

Comment

The use of chlorothiazide is becoming increasingly prevalent as its hypotensive potentiating effect becomes more clearly established. It seems that in addition to its effect in depleting sodium and potassium levels, this drug has still as yet an unexplained apparent effect on the kidneys, causing them to retain uric acid. Of course, another possible explanation might be an increased catabolism of nucleic acids induced by the drug, but this does not seem likely. Further investigations will probably determine the exact mechanism of action.

This side-effect has hitherto been alluded to only once, by Laragh and his associates.[3a] They noted a significant elevation of serum uric acid level in six of eight patients studied, varying from 7.6 mg. % to 11.5 mg. %. The effect could not be attributed to dehydration, since the blood urea level was not concurrently elevated. In all instances of hyperuricacidemia the patient was asymptomatic and the uric acid level returned promptly to normal values on cessation of therapy.

Our observation confirms those of Laragh and others,[3a] but the uric acid level seems to be even more consistently elevated in patients taking chlorothiazide for any length of time. All 12 patients studied in our group revealed significant elevation of blood uric acid levels, ranging from 6.3 to 10 mg. %. Only three of these patients had joint pains in the feet, and only one (case 2) had positive x-ray findings.

We cannot be sure that true gout is actually caused by this elevation of uric acid level, but it appears that gout-like symptoms can be produced in certain individuals and that the intensity of this effect is not necessarily in direct ratio to the height of the uric acid level in the blood. It is not unlikely that those patients who develop joint pain are potentially gouty individuals in whom symptoms have merely been precipitated. Certainly so valuable an agent as chlorothiazide should not be discarded because of this or other side-effects described thus far. The purpose of this preliminary communication is merely to call attention again to the prevalence of hyperuricacidemia with its use and also to indicate that gout-like symptoms may occur in certain patients. Therefore, we feel that those patients who have a history of gout should be watched with especial care. Further study may clarify the mechanism of this side-effect.

COUNCIL ON DRUGS

Report to the Council

The Council has authorized publication of the following report. Nonproprietary terminology is used for all drugs that are mentioned; when such terminology is not considered to be generally well known, its initial appearance is supplemented by parenthetic insertion of names known to be applied to commercial preparations. H. D. KAUTZ, M.D., *Secretary.*

CURRENT STATUS OF THE TREATMENT OF ADRENAL DISORDERS

George W. Thorn, M.D., Don H. Nelson, M.D.
and
Albert E. Renold, M.D., Boston

The availability of precise diagnostic techniques and the synthesis of several important adrenal cortical steroids provide the practicing physician with an unusual opportunity for establishing a correct diagnosis and initiating appropriate therapy in patients with abnormalities of adrenal cortical function. The ever-widening horizon of the nonspecific use of adrenal steroid therapy and the exploration of the beneficial effect of hypophysectomy and adrenalectomy have increased greatly the numbers of patients with evidence of altered adrenal cortical function. The development of accurate and clinically applicable measurements of catechol amine levels in blood and urine has enhanced the accuracy with which pheochromocytoma may be detected and has provided a new and important screening technique which should be applied to all patients with hypertension of undetermined origin.

Hormone Preparations

The structural formulas of the adrenal steroid compounds are represented in figure 1.

Corticotropin.—Corticotropin (Acth, Lyophilized Acthar, Corticotropin, Lyophilized Corticotropin), also known as ACTH, adrenocorticotrophin, and corticotrophin, is available as a lyophilized powder, containing 10 to 40 U.S.P. units per vial for intravenous infusion or for intramuscular injection when dissolved in saline solution. Corticotropin is also available as a solution in gelatin, containing 20 to 100 "clinical units" per cubic centimeter, or in combination with zinc as corticotropin-zinc hydroxide (Cortrophin-Zinc) for intramuscular administration only. These preparations provide prolonged activity (18 to 36 hours) after a single intramuscular injection. "Clinical units" are equivalent approximately to one-third U. S. P. units. A U. S. P. unit equals 1 I. U., which, in turn, represents the biological activity of 1 mg. of corticotropin International Standard, as determined by measurement of the adrenal ascorbic secretion in the hypophysectomized rat.

In diseases of adrenal origin the use of corticotropin is confined largely to diagnostic procedures and for stimulating the adrenal cortex after prolonged steroid therapy. The administration of corticotropin, given intramuscularly and particularly intravenously, may precipitate a crisis in a patient with adrenal cortical unresponsiveness unless the patient is protected by the simultaneous administration of a cortisone-like steroid.

Cortisone-like Steroids.—The cortisone-like steroids, also known as 17-hydroxysteroids, are listed as follows.

Hydrocortisone (Cortef, Cortisol, Cortril, Hycortole, Hydrocortone): Hydrocortisone is available in solution in 50% ethyl alcohol, 100 mg. per 20 cc., and as hydrocortisone sodium succinate (Solu-Cortex), 134 mg. of this compound being equivalent to 100 mg. of hydrocortisone for intravenous or intramuscular injection. It is also available as the acetate in saline suspension for intramuscular use (25 mg. per cubic centimeter) and as 20-mg. tablets for oral use. Hydrocortisone, especially the succinate ester, is the only preparation available for immediate and rapid intravenous use. Conversely, the absorption of hydrocortisone acetate after intramuscular injection is much slower than cortisone and hence should be used only when a prolonged effect from a single injection is desired.

Cortisone (Cortisone, Cortogen, Cortone): Cortisone is available as the acetate in saline suspension (25 and 50 mg. per cubic centimeter) for intramuscular use and in tablets for oral use (5, 10, and 25 mg.). For all practical purposes cortisone and hydrocortisone are equivalent milligram for milligram.

From the departments of medicine, Harvard Medical School and the Peter Bent Brigham Hospital (Drs. Thorn, Renold, and Nelson) and investigator, Howard Hughes Medical Institute (Dr. Nelson).

Prednisone (Deltasone, Deltra, Meticorten) and prednisolone (Delta Cortef, Hydeltra, Meticortelone): Prednisone and prednisolone are available as 2.5-mg. and 5-mg. tablets for oral use. One milligram of prednisone or prednisolone is equivalent to 4 to 5 mg. of cortisone or hydrocortisone. Prednisone and prednisolone exert much less sodium-retaining effect, milligram for milligram, than does cortisone or hydrocortisone.

Triamcinolone (Aristocort, Kenacort): Triamcinolone is available as 4-mg. tablets for oral use. One milligram of triamcinolone is equal to approximately 6 mg. of cortisone or hydrocortisone. This substance, milligram for milligram, possesses even less sodium-retaining effect than does prednisone or prednisolone.

Fludrocortisone (Alflorone, F-Cortef, Florinef): Fludrocortisone is available as the acetate in 0.1-mg. and 1.0-mg. tablets. This derivative of hydrocortisone is approximately 25 times as active as cortisone, hydrocortisone, and desoxycorticosterone (Cortate, Decortin, Decosterone, Doca, Percorten); hence, its sodium-retaining action is very great in relation to its cortisone-like action.

Sodium-Retaining Adrenal Steroids.—All adrenal steroids are "sodium-retaining" to some extent under normal conditions. However, unless very large doses of cortisone, hydrocortisone, and prednisone are employed, this activity is not prominent.

Fludrocortisone: Fludrocortisone, as noted previously, is an extremely active sodium-retaining hormone, 1 mg. by mouth being equivalent to 25 mg. of desoxycorticosterone given by injection.

Desoxycorticosterone: Desoxycorticosterone is available for intramuscular injection as the acetate in sesame oil (5 mg. per cubic centimeter). For prolonged effect (15 to 30 days), it is available as a suspension of the trimethylacetate ester (25 mg. per cubic centimeter) and as the acetate in 2-mg. and 5-mg. buccal tablets for sublingual use.

Aldosterone: Aldosterone, the naturally occurring sodium-retaining hormone in man, is not available commercially.

Special Considerations.—The high potency of fludrocortisone, in respect to both its cortisone-like effect and its sodium-retaining effect, makes the administration of this substance particularly advantageous when adrenocorticotropin tests are being carried out. Patients with suspected Addison's disease can be given 1 to 2 mg. of this substance daily while the tests are being conducted, without concern for the hormone derived from this substance which may appear in the urine, since the quantity is so small. Furthermore, larger doses of this substance may be substituted in patients on prolonged cortisone therapy in whom it is desirable to test reserve adrenal capacity before hormone therapy is reduced or discontinued. Thus, 4 to 5 mg. of fludrocortisone is equivalent to 100 mg. of cortisone or hydrocortisone. However, the dietary sodium should be rigidly restricted during the period of substitution to avoid excessive sodium retention. Supplementary potassium chloride (3 to 6 Gm. daily) may also be given.

Acute Adrenal Crisis

Such an emergency may be precipitated in a patient with chronic adrenal cortical insufficiency by the superimposition of stress, such as intercurrent infection, surgery, or trauma. It may also be precipitated in patients on long-term, large-dosage cortisone therapy by the sudden withdrawal of hormone therapy or by the superimposition of stress without an accompanying increase in steroid therapy. Acute adrenal crisis may occur as a complication of anticoagulant therapy (hemorrhage into the adrenal gland) or may present itself as shock in conjunction with surgery, hemorrhage, or acute infection. *It is nearly always impossible to establish* with certainty the diagnosis of acute adrenal crisis at the time a patient presents the picture of acute hypotensive shock.

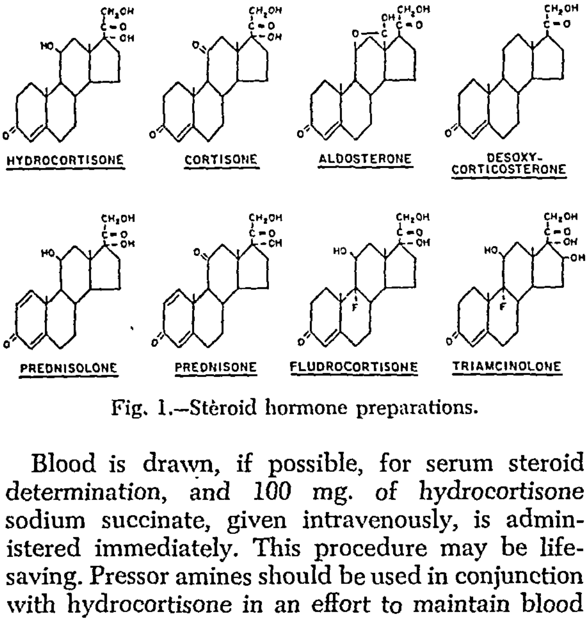

Fig. 1.—Steroid hormone preparations.

Blood is drawn, if possible, for serum steroid determination, and 100 mg. of hydrocortisone sodium succinate, given intravenously, is administered immediately. This procedure may be lifesaving. Pressor amines should be used in conjunction with hydrocortisone in an effort to maintain blood pressure. The use of whole blood, plasma, or albumin and electrolyte solutions given intravenously will be dictated by the circumstances surrounding the circulatory collapse.

If the diagnosis appears to be confirmed by the initial response of the patient to therapy, by the blood steroid values, or by history, then an intravenous drip containing 1,000 cc. of 5% dextrose in isotonic sodium chloride solution, to which is added another 100 mg. of hydrocortisone sodium succinate, is continued, and 100 mg. of cortisone acetate is injected intramuscularly. With the termination of the intravenous infusion, the patient is given 50 mg. of cortisone acetate intramuscularly or orally every 8 hours for the subsequent 24 hours, then every 12 hours for the next 24 hours, and then a total of 50 to 75 mg. per day by mouth in two or three divided doses or intramuscularly by injection. During this period, in conjunction with the large doses of hydrocortisone and cortisone plus isotonic sodium chloride solution given intramuscularly, no salt-retaining hormone is necessary. When the dose of cortisone is reduced below 75 mg. daily, the use of supplementary saline solution or a salt-retaining hormone, either desoxycorticosterone acetate intramuscularly or fludrocortisone orally, may be required.

Chronic Primary Adrenal Cortical Insufficiency, Including Addison's Disease

A definitive diagnosis of adrenal cortical insufficiency should not be made until a lack of response to intravenously administered corticotropin has been demonstrated, since in the presence of certain abnormal states, such as sarcoid and rheumatoid arthritis, intramuscularly administered corticotropin may not reach the adrenal cortex in adequate concentration. One may follow the urinary steroids or the blood steroid values. The authors prefer the former as being, in general, a more reliable measure of adrenal cortical reserve. The response to corticotropin is also useful in differentiating primary adrenal insufficiency from that secondary to pituitary failure (fig. 2). Blood corticotropin values will be elevated in untreated patients with primary adrenal cortical insufficiency and low or absent in those with pituitary insufficiency.

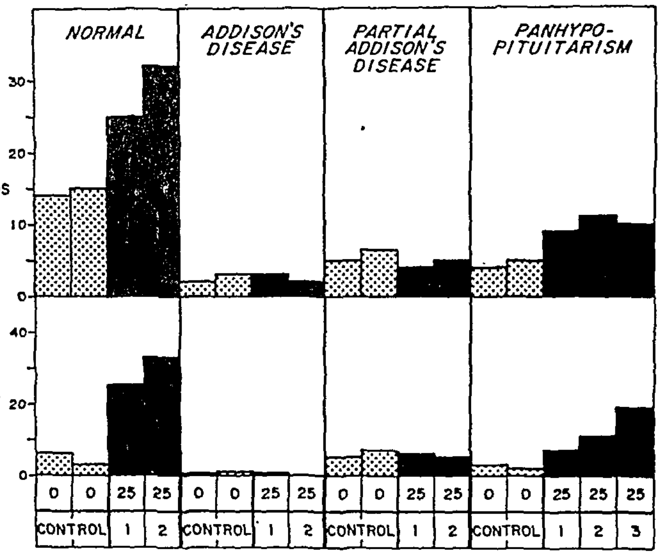

Fig. 2.—Response to intravenously given corticotropin in adrenal insufficiency.

Hormone therapy is indicated in any patient with impaired adrenal cortical reserve who exhibits weakness, weight loss, gastrointestinal symptoms, hyperpigmentation, fasting hypoglycemia, hypotension, abnormal electroencephalographic tracing, or in whom an abnormal response to a water load may be demonstrated. All patients with chronic adrenal deficiency will exhibit improved biochemical and physiological response to stress when given cortisone or one of its derivatives. Whether supplementary sodium chloride or a salt-retaining hormone is required in addition, and how much, will be determined by the patient's blood pressure, cardiac status, serum sodium and potassium levels, hematocrit value, and changes in body weight. The authors prefer to use a small dose of salt-retaining hormone in most patients with Addison's disease unless increasing age, with a rise in blood pressure, or renal and cardiac changes contraindicate.

Cortisone or hydrocortisone by mouth provides the basic maintenance therapy in a dosage of 25 to 50 mg. daily. For most patients one-half to two-thirds of the daily dose is given on arising, the remainder late in the afternoon. Supplementary hormone (50 to 100 mg. daily) is given in the presence of infection or unusual stress. If nausea or vomiting occurs, cortisone may be given intramuscularly; in an acute crisis, the intravenous administration of hydrocortisone is mandatory, as outlined in the foregoing section. The presence of healed or active tuberculosis is no contraindication to cortisone therapy, although the authors limit the maintenance dose to 20 to 25 mg. per day in conjunction with chemotherapy. Under the circumstances, the usual maintenance dose is well tolerated and may even accelerate recovery of the patient.

Adequate cortisone therapy should induce a regression of pigmentation and a gain in weight; hypoglycemic manifestations should be controlled; and a normal diuresis after a water load should be evident. Abnormalities in the electrocardiogram and electroencephalogram should disappear. Initially, chronically deficient patients may exhibit euphoria and an undesirable psychological response to cortisone, so that a dose not exceeding 12.5 mg. per day may be all a patient can comfortably tolerate. Later the dose may be increased slowly to 25 mg., without untoward symptoms. Patients with preexisting peptic ulcer may experience difficulty in tolerating 25 mg. daily of cortisone or its equivalent. In the rare combination of diabetes mellitus and adrenal cortical insufficiency, it is preferable to use a normal maintenance dose of cortisone (25 to 37.5 mg. daily) and sufficient insulin to maintain normal glucose levels. It is desirable for these patients to take part of their cortisone late at night or very early in the morning.

Most patients with chronic adrenal cortical insufficiency will be on maintenance therapy with cortisone or hydrocortisone. There is no advantage n using a preparation which is less salt-retaining, . e., prednisone or triamcinolone. In fact, for a few atients, cortisone or hydrocortisone alone with a generous dietary sodium intake may avoid the necessity of supplementary sodium-retaining hormone.

Most patients will do better on a small dose of sodium-retaining hormone. For this purpose, one has three choices: (1) fludrocortisone acetate by mouth in a single daily dose of 0.1 to 0.2 mg.; (2) desoxycorticosterone acetate in oil, the daily intramuscular dose being 1 to 5 mg.; or (3) desoxycorticosterone trimethylacetate, a monthly intramuscular injection of 25 to 75 mg. At a dose level of 0.1 to 0.2 mg. daily, the cortisone equivalent of fludrocortisone can be disregarded, i. e., it will not amount to more than 5 mg. of cortisone equivalent or hydrocortisone equivalent. If larger quantities of *fludrocortisone are required, i. e., 0.5 mg. or more,* then the cortisone equivalent of this sodium-retaining compound must be considered.

The majority of the authors' patients are on maintenance therapy with either 0.1 to 0.2 mg. of fludrocortisone administered orally daily or 25 to 50 mg. of the long-acting desoxycorticosterone ester given intramuscularly every two to four weeks. Because of the ease with which the oral administration of fludrocortisone can be manipulated, there is a growing tendency to substitute this therapeutic regimen for the monthly injections of long-acting desoxycorticosterone derivatives. Desoxycorticosterone acetate, with a duration of action of 12 to 24 hours, is a useful preparation for a patient who is experiencing nausea, vomiting, or diarrhea in which maximum sodium retention is desirable and in which oral medication may not be well tolerated. A dose of 5 to 10 mg. daily (1 to 2 cc.) of the oil solution given intramuscularly will ensure adequate sodium retention in the presence of normal kidney function. In all instances, it is desirable to establish the optimum dose of sodium-retaining hormone by carefully following changes in body weight, blood pressure, heart size, and serum sodium and potassium levels.

In summarizing, the condition of the majority of patients with primary chronic adrenal cortical insufficiency will be well maintained on a program which includes 25 to 50 mg. daily of cortisone or hydrocortisone and 0.1 to 0.2 mg. of fludrocortisone by mouth. In the presence of complications, the dose of cortisone should be increased immediately.

Chronic Secondary Adrenal Cortical Insufficiency (Hypopituitarism)

In the presence of anterior pituitary deficiency, adrenal cortical insufficiency is modified in three essential respects. First, pigmentation is unusual, due presumably to the fact that corticotropin and melanocyte-stimulating hormone are not present in increased quantities. Secondly, the manifestations of adrenal cortical insufficiency may be tempered significantly by concomitant thyroid and gonadal deficiencies. And thirdly, since corticotropin does *not exert the same primary control over aldosterone* secretion as it does in the case of the adrenal 17-hydroxysteroids, sodium deficiency may be less pronounced or nonexistent, a fact consistent with relatively normal urinary aldosterone values in patients with pituitary insufficiency. For practical purposes, one treats adrenal, thyroid, and gonadal deficiencies simultaneously in chronic anterior pituitary deficiency. One could employ corticotropin in these patients, but the practical disadvantages of a daily intramuscular injection of hormone favor the use of cortisone or hydrocortisone given orally. The doses of thyroid and cortisone are advantageously increased or decreased simultaneously, as the patient's cortisone require*ment may increase with an increased dose of thy*roid. Sodium liothyronine (Cytomel), also known as sodium L-triiodothyronine, may have an advantage over thyroid extract or thyroxin in some patients. The dose of cortisone or hydrocortisone in patients with chronic pituitary insufficiency is generally somewhat less than that for patients with Addison's disease. However, in the presence of unusual stress, a large supplement of cortisone will be required.

Iatrogenic Adrenal Insufficiency

Patients who receive prolonged steroid therapy for diseases such as rheumatoid arthritis, disseminated lupus, pemphigus, and asthma may develop temporary or even permanent adrenal cortical inhibition. Presumably the action of the steroids is to depress the hypothalamic-pituitary system. Withdrawal of hormone therapy may precipitate a relapse of the underlying disease, or, if adrenal function is severely inhibited, it may precipitate an acute adrenal crisis. One of the problems encountered in reducing or terminating steroid therapy in such patients is the difficulty of measuring reserve adrenal cortical function without discontinuing therapy.

Today, with the availability of such highly active steroids as fludrocortisone, it is possible to substitute this compound for cortisone or prednisone (i. e., 1 mg. of fludrocortisone for 25 mg. of cortisone or 5 mg. of prednisone) and carry out an adrenocorticotropin test, using the urinary steroid response (17-hydroxysteroids and 17-ketosteroids) as the measure of responsiveness. In this test, corticotropin should be given intravenously (25 units over an eight-hour period is suggested) for at least three days. The small quantity of metabolites of fludrocortisone will not affect the significance of the urinary values. However, when fludrocortisone is used, because of its intense sodium-retaining potency, dietary sodium chloride should be rigidly restricted, but 2 to 6 Gm. of potassium chloride daily may be given. The period of trial should be kept as short as possible, and a mercurial diuretic or chlorothiazide (Diuril) may be given if excessive fluid retention occurs.

Failure to observe an adequate response to intravenously administered corticotropin, although not necessarily indicating permanent adrenal atrophy, certainly suggests that hypoadrenalism will complicate withdrawal of steroid therapy. Unfortunately, an adequate response to corticotropin does not necessarily indicate that the patient's own hypothalamic-pituitary system will secrete an adequate quantity of corticotropin when steroid therapy is discontinued. At present, there is no practical way of deciding this point without careful withdrawal of steroid therapy and an analysis of baseline urinary steroid values.

This discussion naturally raises the problem of whether one should employ corticotropin therapy, intermittently throughout the course of prolonged steroid therapy, in order to prevent or minimize severe adrenal atrophy. It is true that the adrenal responsiveness may be maintained by such a technique, but unfortunately such a procedure will in no way minimize the hypothalamic or pituitary inhibition which may be the more serious problem. Recent studies have indicated that in disease states, such as asthma, adrenal cortical inhibition may be significantly modified by alternating a high dose of steroids for one to two days with a respite of one to two days, without loss of clinical regulation. This technique has not been applied systematically, nor has the adrenal response been studied accurately in other disease states. However, the program deserves further investigation.

Cushing's Syndrome

The clinical manifestations of Cushing's disease (pituitary basophilism) and those of Cushing's syndrome (adrenal cortical hyperfunction) are due to the production of an increased amount of adrenal steroids. The object of treatment is to decrease or eliminate the abnormal hormone secretion. This can be accomplished with certainty by complete removal of a tumor or of both adrenals if hyperplasia is present, theoretically by chemical inhibition of the pituitary-adrenal secretions or the blocking of the end-organ responsiveness to these hormones, and by ablation (surgery or radiation) of the pituitary when it is the primary site of the disorder.

Cushing's syndrome should be considered in every patient presenting hypertension, diabetes, osteoporosis, or skin manifestations characterized by ecchymoses and striae. Psychological manifestations are also a prominent aspect of the disorder. Definitive diagnosis rests upon detecting a tumor of the pituitary, adrenal, or ovary and the demonstration of an abnormal steroid excretion in the urine. The response to corticotropin and the character of the steroid excretion pattern may prove helpful in suggesting a histological diagnosis, i. e., carcinoma vs. adenoma vs. hyperplasia.

Cushing's syndrome is a serious but usually remediable disorder. It is unfortunate that many patients are permitted to progress to the point that therapy designed to correct the adrenal hormone secretion may not restore the individual to health because of complicating factors such as osteoporosis and fractures, permanent diabetes, hypertension, or severe psychological changes. For this reason, an early and a more radical approach to treatment is to be encouraged.

Tumor of the pituitary is demonstrated rarely. Radiation to the pituitary in such cases should be tried initially unless local pressure signs from the tumor (impairment of vision, headaches) indicate the need for immediate surgical intervention. If irradiation is carried out, there is no need for supplementary hormone therapy; if hypophysectomy is done, the patient should be carried through the operation with substitution therapy, as outlined in the section on acute adrenal crisis. The postoperative care will be that of a pituitary-deficient patient. In the case of removal of a tumor of the adrenal or ovary, the same hormone substitution program is utilized during or after surgery, as outlined in the section on acute adrenal crisis. However, during the immediate postoperative period after removal of a tumor of one adrenal, corticotropin should be tried, with urinary steroid measurements, to determine whether the remaining adrenal cortical tissue will function adequately.

In the presence of bilateral adrenal hyperplasia, the choice lies between an attempt to control the disease by pituitary irradiation, a subtotal adrenalectomy (usually removing one adrenal completely and two-thirds to three-fourths of the second adrenal), or complete bilateral adrenalectomy. The "cures" from irradiation of the pituitary alone are relatively infrequent and unpredictable but can be spectacular. Since several months must elapse before final evaluation of irradiation treatment can be made, it would seem wise to reserve irradiation for those patients in whom the disease is relatively mild and in whom one can be almost certain that tumor exists. As regards the choice of complete or subtotal adrenalectomy, the authors strongly favor the former, since recurrence of the disease is frequent when any adrenal cortical tissue remains and since in practice one must be prepared for adrenal insufficiency, at least in the presence of stress, in the majority of patients with a small remnant of tissue. Experience alone and the seriousness of the disease in the individual patient must weight the judgment of the physician and surgeon in determining the risk of recurrence if any tissue is left and the certainty of adrenal cortical insufficiency if all tissue is removed.

In recent years the development of hyperpigmentation, despite a level of cortisone adequate for all other needs, has been observed in certain adrenalectomized patients. This may occur in association with progressive enlargement of the sella turcica. Whether irradiation of the pituitary, carried out prior to or after adrenalectomy, will prevent or correct this evidence of excessive corticotropin or secretion of the melanocyte-stimulating hormone remains to be seen.

After adrenalectomy in patients with Cushing's syndrome, the dosage of cortisone or hydrocortisone must be followed carefully. Too rapid reduction may result in symptoms of acute adrenal insufficiency in a patient whose tissues have adjusted over the years to a relative excess of hormone. On the other hand, the prolonged administration of excessive doses of cortisone may accentuate the symptoms of Cushing's syndrome. With a good urine output, patients should be given generous quantities of potassium during the immediate postoperative period, i. e., at least 40 to 80 mEq. per 24 hours. In general, the dose of cortisone will be 300 mg. on the day of operation, 200 mg. on the first postoperative day, 150 mg. on the next, then 100 mg. for two to three days, 75 mg. for one week, and, finally, 50 to 62.5 mg. daily for an indefinite period. When the dose of cortisone is reduced below 75 mg. per day in the bilaterally adrenalectomized patient, additional salt or supplementary sodium-retaining hormone will be required, i. e., 1 to 5 mg. of desoxycorticosterone acetate given intramuscularly once daily or 0.1 to 0.2 mg. of fludrocortisone orally. Potassium supplementation, 3 to 6 Gm. daily, if tolerated, and testosterone propionate (25 mg. weekly for female patients) should be continued indefinitely if tolerated.

Adrenal Virilism and the Adrenogenital Syndrome

The clinical manifestations of excessive adrenal androgen secretion may be caused by a tumor or hyperplasia of the adrenal cortex. Steroid analysis of the urine, particularly the 17-ketosteroids, and fractionation of the 17-ketosteroids into those derived from hydrocortisone and those derived from adrenal androgens will be of specific diagnostic aid. Studies on the inhibition of adrenal androgen by cortisone or its derivatives, preferably prednisone or fludrocortisone, will be of additional help in differentiating tumor from hyperplasia and indicating whether medical therapy, i. e., long-continued cortisone therapy, is therapeutically feasible or whether surgery must be resorted to if the disorder is to be cured. The use of the most potent cortisone-like substances in the suppression test is to be encouraged, since the small quantity of ketosteroids derived from the exogenously administered hormone will not interfere significantly with the evaluation of the test. It is helpful to note that prednisone is not excreted as 17-ketosteroid material and hence can be advantageously used. This substance does, of course, give rise to increased 17-hydroxysteroid material in the urine.

Patients with virilism or the adrenogenital syndrome may display evidence of deficiency of sodium-retaining hormone. Under these circumstances, the clinical picture may be complicated by the presence of hypotension, weakness, small heart size, azotemia, hyponatremia, and hyperkalemia. The use of fludrocortisone (0.1 to 0.2 mg. daily by mouth) or a biweekly or monthly injection of the long-acting desoxycorticosterone trimethylacetate given intramuscularly (25 to 50 mg.) should provide satisfactory regulation. The dosage will, of course, be adjusted to maintain a normal blood pressure and electrolyte balance.

If a tumor is suspected in a patient with virilism or adrenogenital syndrome, surgery is advised; the care of the patient is similar to that outlined under Cushing's syndrome, with the exception that the cortisone dosage may be reduced much more rapidly postoperatively since hypercorticism was not present initially. A trial with corticotropin is essential, however, to test the adequacy of the remaining adrenal tissue before supplementary hormone is withdrawn completely. There is usually no need for potassium medication, testosterone, or sodium-retaining adrenal steroid therapy.

The problem is more difficult when virilization or adrenogenital syndrome is due to bilateral adrenal hyperplasia. If adequate suppression can be obtained with a dose of cortisone or cortisone-like steroid which will not induce the undesirable side-effects of Cushing's syndrome, medical management is feasible. Cortisone or hydrocortisone given intramuscularly is recommended for the initiation of treatment, i. e., 100 mg. daily for adults and older children; 25 mg. daily will suffice for infants. The minimum dosage required subsequently will be determined on the basis of the 24-hour urinary ketosteroid excretion. An effort should be made to maintain the level of 17-ketosteroids below 2 mg. in infants, below 7 mg. in older children, and below 10 mg. in adults. Infants will require 25 to 37.5 mg. of cortisone intramuscularly every three or four days; older children will require 50 to 100 mg. every three or four days. The dosage of hormone given orally will be two to three times that employed intramuscularly. The excreted products (17-ketosteroids) from the administered hormone will complicate the interpretation of the suppressive action of the therapy unless substances such as prednisone are used.

It is desirable to use supplementary potassium medication, i. e., 3 to 6 Gm. of potassium chloride daily, in an effort to minimize the hypochloremic, hypokalemic alkalosis which is so characteristically induced by long-term steroid therapy. The return of normal menstrual periods, the disappearance of acne, the regression of body hair, and the attainment of a normal female configuration comprise the criteria of success. Unfortunately, the inhibition of excessive hair growth may be very difficult to attain with steroid therapy.

In the event that suppression of androgen secretion cannot be obtained with a dose of cortisone-like steroid, which in turn does not induce Cushing's syndrome, one is faced with a difficult decision. Should one proceed with adrenal resection? In contrast to the approach to a patient with Cushing's syndrome, which is in itself life-threatening from a clinical viewpoint, mild virilism or the adrenogenital syndrome is not life-threatening, except in its serious psychological implications. If surgery is undertaken, the following steps are suggested:

1. Unless the adrenals are approached by an abdominal incision which permits the exploration of the ovaries, a pelvic exploratory operation or a culdoscopy with visualization of the ovaries must be undertaken before adrenal surgery. Such an initial step will permit the physician to evaluate ovarian function and the possibility of ovarian disease and to exclude the ovary as a source of androgen-secreting tissue.

2. In contrast to the approach to a patient with Cushing's syndrome in which radical bilateral complete adrenalectomy is to be encouraged, the patient with adrenal hyperplasia and the adrenogenital syndrome would do well to have one adrenal removed and only a portion of the second, in the hope that control of the syndrome might be accomplished by a more conservative procedure. No great difficulty should be encountered if a second, complete adrenalectomy is ultimately deemed necessary. The operative and postoperative needs for hormone therapy will be similar to those noted previously. Again, if a subtotal adrenalectomy is performed, a response to corticotropin should be undertaken prior to discontinuing supplementary hormone therapy. Of course, if sodium-retaining hormone had been required preoperatively, it will be necessary to continue this therapy. In addition, patients with unilateral adrenal removal and partial resection of the second gland may require supplementary sodium chloride or sodium-retaining hormone (fludrocortisone) by mouth once daily, desoxycorticosterone trimethylacetate given intramuscularly once monthly, or desoxycorticosterone acetate in oil, intramuscularly for daily use.

Finally, no patient with menstrual irregularities and a virilizing syndrome should have her adrenal explored (in the absence of a securely documented, unilateral adrenal mass) until ovarian exploration has been carried out. A deficiency of mineralocorticoids should also be excluded in all adrenogenital cases.

Primary Hyperaldosteronism (Conn's Syndrome)

All patients with hypertension, with unexplained episodes of weakness, with unexplained hypochloremic, hypokalemic alkalosis, and with unexplained polyuria and polydipsia should be screened for primary hyperaldosteronism. The majority of patients with primary hyperaldosteronism do not exhibit edema. The latter finding is characteristic of secondary hyperaldosteronism. A definitive diagnosis of primary hyperaldosteronism may be difficult to establish, because urinary aldosterone determinations are difficult to carry out, and norma values have been encountered in well-documente cases. It was hoped that a determination of th salivary sodium:potassium ratio, which can b easily measured, might provide a readily availabl screen for cases of primary hyperaldosteronism since aldosterone is known to affect the sodium concentration of saliva. At present it can be state that a value of more than 0.5 in salivary sodium potassium ratio is strong evidence against excessiv aldosterone secretion at that time. (The test i carried out in the morning, with care being take that no dentifrice or other sodium-containing med cation has been used; the analysis is made on th second 10-minute specimen with paraffin chewing the first 10-minute specimen having been di carded.) Values of less than 0.5 are frequent found in secondary hyperaldosteronism and probably in other conditions. Whether the salivar sodium:potassium ratio will assist in excluding th many patients who do not need definitive hormon studies remains to be seen. Of course, every patien with unexplained hypertension should have pyel grams, which may prove helpful in detecting large tumor. Unfortunately, small tumors bilateral adrenal hyperplasia are not likely to be detected by this means.

The diagnosis of primary hyperaldosteronism should be considered seriously in the presence of hypertension and hyperchloremic, hypokalemic alkalosis with a normal potassium content of the urine, i. e., 40 to 50 mEq. or more per 24 hours. Sodium restriction and potassium medication should ameliorate the symptoms, whereas unrestricted sodium and low-potassium intake should aggravate the disorder. Changes in the electrocardiogram, suggesting hypokalemia, may initiate the search for the disorder in patients with hypertension and cardiac abnormalities.

Since primary hyperaldosteronism is a life-threatening disorder, an active and aggressive attitude should be taken toward the diagnosis and treatment of the syndrome. The removal of a tumor presents no unusual therapeutic problems except that a generous potassium supplement should be provided preoperatively and postoperatively. An aldosterone-secreting tumor will *inhibit* the production of aldosterone by the opposite adrenal but will not inhibit the adrenal secretion of 17-hydroxysteroids and androgenic steroids. Postoperatively, one must watch for excessive sodium loss and be prepared for the administration of supplementary sodium salts or salt-retaining hormone as needed. In the absence of a tumor, a complete bilateral adrenalectomy may be necessary in a patient with hypertension and unexplained hypokalemia. Histological examination of the adrenals, certainly frozen sections, may not prove helpful in guiding the surgeon.

The operative and postoperative care of such patients, as far as adrenal hormone replacement is concerned, is identical with that previously described. However, since hypercorticism did not exist preoperatively, one may attain normal cortisone-replacement levels relatively rapidly after operation. Again, hypokalemia is probably the most serious immediate postoperative complication. One note of caution should be mentioned. Since patients with this condition may lose sodium rapidly and in large quantities postoperatively, if unsupervised, the patient may develop hyperkalemia as a consequence of excessive sodium loss and supplementary potassium medication at a time when his body tissues are markedly depleted of potassium. Daily serum sodium and potassium determinations are essential in the immediate postoperative management of these patients.

Secondary Hyperaldosteronism

The syndrome of edema, associated with increased urinary values for aldosterone, implies a causal relationship between secondary hyperaldosteronism and the edematous state. Four points deserve consideration. 1. An increase in urinary aldosterone excretion does not necessarily, but in all probability does, imply increased aldosterone production. 2. It has been shown that patients with heart failure and generalized edema may have normal aldosterone values until treatment is instituted. 3. A decrease in aldosterone excretion has been attained with adrenal inhibition, without a concomitant increase in sodium excretion, suggesting that, in such cases, secondary hyperaldosteronism was not at that particular time the determining factor in the production or maintenance of the edematous state. 4. A decrease in aldosterone excretion produced by inhibition of adrenal secretion or the administration of a competitive substance has resulted in a sodium diuresis in certain patients with edema and elevated urinary aldosterone values. In these patients it is presumed that secondary hyperaldosteronism has been an important factor in the genesis or maintenance of the edematous state. Finally, adrenalectomy in certain patients with edema has been followed by a sodium diuresis and marked clinical improvement in patients with hypertensive cardiovascular disease, the nephrotic syndrome, and cirrhosis with ascites.

From these considerations there is little doubt that secondary hyperaldosteronism is a frequent concomitant of the edematous state. There is considerable uncertainty as to its importance at any given stage in a patient's decompensation. Medical inhibition of aldosterone production or competition with the action of aldosterone on renal tubular mechanisms would appear to be the most promising approach to the clinical problem. Bilateral complete adrenalectomy for secondary hyperaldosteronism should be reserved for those patients in whom a direct relationship between sodium retention and hypersecretion of aldosterone can be demonstrated, and in whom the risk of major surgery may be justified by an important degree of or prolonged clinical benefit. The specific hormone requirements for the management of such patients will be similar to those employed in other cases of bilateral adrenalectomy, with the exception that cortisone-like steroids of less sodium-retaining capacity, i. e., prednisone and triamcinolone, will, in general, be preferred during the postoperative period.

Pheochromocytoma

Recent advances in the chemical determination of catechol amines in the blood and urine have provided definitive techniques for detecting the presence of pheochromocytoma in patients presenting paroxysmal or sustained hypertension, particularly when associated with anxiety, dizziness, palpitation, nausea, vomiting, sweating, precordial pain, and peripheral vasoconstriction.

After the demonstration of a tumor or elevated levels of urinary or blood catechol amines, surgical exploration should be undertaken. The use of intravenously administered phentolamine (Regitine) methanesulfonate prior to and during operation may be lifesaving in preventing an excessive rise of blood pressure. A solution of this substance should be available throughout the operation. Later with the ligation of adrenal vessels and the removal of a tumor, one must be prepared for a sudden and precipitous fall in blood pressure. This may be corrected by the use of levarterenol (Levophed) bitartrate given intravenously (never subcutaneously or intramuscularly). Phenylephrine (Neo-Synephrine) hydrochloride may be given subcutaneously to correct mild hypotensive episodes. Perhaps the most important postoperative maneuver is to keep the patient undisturbed for several hours on the operating-room table, as a sudden change in posture may precipitate collapse. Postoperatively, adrenal steroid therapy is not required unless a bilateral adrenalectomy has been performed. Postoperatively, the blood pressure can be controlled with phenylephrine. In the more severe cases it may require 48 to 72 hours before supportive medication can be withdrawn.

This study was supported, in part, by grants from the Eugene Higgins Trust, Harvard Medical School, and the John A. Hartford Foundation, New York.

COUNCIL ON FOODS AND NUTRITION

The following is one of the six papers presented at the symposium on "Nutrition in Pregnancy" in Columbia, Mo., Oct. 11, 1957. This symposium was sponsored by the Council on Foods and Nutrition, with the cooperation of the Boone County Medical Society, the University of Missouri School of Medicine, and the Adult Education and Extension Service of the University of Missouri.

VANDERBILT COOPERATIVE STUDY OF MATERNAL AND INFANT NUTRITION

XII. EFFECT OF REPRODUCTIVE CYCLE ON NUTRITIONAL STATUS AND REQUIREMENTS

William J. McGanity, M.D., F.R.C.S.(C), Edwin B. Bridgforth, A.B.
and
William J. Darby, M.D., Ph.D., Nashville, Tenn.

Numerous reports concerning the influence of maternal nutrition upon the course of pregnancy or the health of the infant have appeared during the past 20 years. These have led to the concept that the increased physiological nutritional requirements during pregnancy and lactation enhance the likelihood of nutritional deficiencies occurring during the reproductive interlude. Metabolic adjustments during this period may so alter the metabolism in some patients that a conditioned deficiency state may develop in spite of what would otherwise be considered an adequate dietary intake. The expectation of these alterations in nutrient requirement is reflected in estimates of nutrient allowances such as the Recommended Dietary Allowances of the Food and Nutrition Board.[1]

It has been hypothesized that a number of maternal and fetal complications peculiar to the reproductive interlude may be related to the nutritional level of the mother's diet.[2] From studies, such as Warkany's, on a variety of species of experimental animals, it is clear that the maternal nutritional level can influence fetal development, viability, birth weight, and other physiological attributes of the newborn animal. However, extrapolation from laboratory findings to situations commonly encountered in obstetric practice has resulted in inconsistencies and confusion of claims. Some of these have arisen as a result of the physician's failure to distinguish between conditions of obvious nutritional origin and conditions in which the etiology may possibly have a nutritional component.

Prior to any consideration of the effects of reproduction on maternal nutrition, it is desirable to recognize and to identify the present-day expectant mother in America. To base our premise on her pre-World War II status would be a gross injustice. Although obesity remains a national nutritional problem, the young mother of today is no longer willing to accept obesity as her price for having children, and she is doing something about it even prior to conception. Recent reports[3] have indicated that the average caloric consumption by nonpregnant, nonlactating women is 400 to 500 calories below the National Research Council's dietary allowance. This should be anticipated when one compares the modern woman's conservation of energy, resulting from our present-day centrally heated, motorized, and mechanized culture, with the energy expended by women in the past.

The metabolic and physiological changes during the reproductive interlude are manifest in every organ and system of the maternal body. We do not always take cognizance of the fact that the 40 weeks of gestation is the period of the most rapid growth and development known to medicine, that pregnancy is the most potent anabolic force we have, or that there is a placental barrier. It is also necessary to recall that alterations such as increased basal metabolism and blood volume, and decreased gastric acidity, gastrointestinal motility, and renal threshold do occur and may influence significantly one's interpretation of maternal nutriture.

It is the unquestioned aim of maternal nutriture to provide adequate amounts of the essential nutrients from conception through parturition and lactation. These nutrients provide for the mother's maintenance and the growth and development of the fetus and protect each from complications during or after the reproductive cycle.

Dietary, Biochemical, and Clinical Assessment

We have had the opportunity of making nutritional observations on a total obstetric clinic population over a period of years at Vanderbilt. The sample consisted of 2,338 pregnant white women who presented themselves for prenatal care at the

---

From the Department of Obstetrics and Gynecology and Preventive Medicine and the Division of Nutrition of the Department of Biochemistry, Vanderbilt University School of Medicine.

outpatient clinic. Economically, these patients fell into the lower income brackets ($1,200 to $3,000 per annum). From this study we obtained an objective quantitative description of changes that occur in nutritional physiology during the reproductive interlude. Our results were based on obstetric and pediatric performance and dietary, biochemical, and clinical assessment obtained prior to the recognition or development of any abnormality. The several observations were repeated during each trimester and at the postpartum examination. From the data amassed, the effect of pregnancy and lactation on maternal nutritional status was determined, and a yardstick was provided for nutritional requirements in pregnancy. A great effort was made to prevent revealing the results of the nutritional estimates to the physician or patient. This avoided influencing management of the diet.

Table 1.—*Average Daily Nutrient Intakes for Each Trimester*

	Trimester		
	1st	2nd	3rd
Diet records, No.	278	1,222	1,665
	Means		
Total calories	2,110	2,200	2,020

Riboflavin, mg.	2.5	2.5	2.3
	Medians		
Total vitamin A activity, I.U.	6,500	6,600	5,900
Vitamin C, mg.	66	62	55

Nutrient Intakes.—The average daily nutrient intakes of this group of patients are indicated in table 1. We did not (and do not) routinely prescribe pharmaceutical supplements in our clinic. Seventy-three per cent of our patients received no dietary supplement. In the remaining 27%, the type and period of supplementation varied, but it was seldom extended throughout the whole period of gestation. In calculating nutrient intakes, the contribution made by pharmaceutical supplements is not included. Although these average nutrient intake levels are not all equal to those of the recommended allowances from the Food and Nutrition Board, they are not disturbingly low. There is a somewhat surprising decrease of approximately 200 calories in intake between the second and the third trimester. *This is associated with a similar decrease in the consumption of most of the other individual nutrients.* As will be seen subsequently, considerable variation occurred around these average figures. The food patterns of these women were gratifyingly varied and revealed no widespread disturbing food prejudices or fads associated with pregnancy. Their diets showed frequent consumption of the necessary basic nutrients supplied by milk and eggs, green and yellow vegetables, and citrus and other fruits. Individuals revealed a remarkable degree of constancy of nutrient intake between successive trimesters and even successive pregnancies.

Why did the decrease in caloric consumption between the second and the third trimester occur? Is it a reflection of maternal design or of the physician's advice? We know that the physician's advice was responsible, in a large part, for the decline in caloric intake of patients who were obese, who gained weight rapidly, or who were preeclamptic. However, the decreased intake was not limited to these categories. It appears that the recommended standards of caloric intake during pregnancy are too high for today's expectant mother. It is reasonable to postulate that *the reduced intake during the latter months of pregnancy* reflects lessened activity on the part of the mother.

Changes in Body Fluids.—The biochemical measurement of body fluids revealed nutrient levels consistent with values that one expects in healthy populations. In both the blood and the urine several alterations in nutrient levels were found. These reflected gestational lactational influences and revealed *significant differences in nutrient concentrations* when compared with nonpregnant values. These alterations fell into the following categories: 1. The mean hematological values (but not the indexes), total serum protein, and serum vitamin A, and the urinary excretion of thiamine and riboflavin showed a decline in concentration during the first 32 to 34 weeks of gestation and a postpartum rise, mirroring the changes in circulating blood volume. *Figure 1 illustrates this pattern for serum protein* determinations. The dietary intake of these nutrients does not account for this observed biochemical change. 2. For the mean levels of serum carotene and tocopherol and the urinary excretion of N′-methylnicotinamide, a progressive increase in concentration during pregnancy and a postpartum decline were found. Figure 2 shows this for serum vitamin A and carotene levels. For the two fat-soluble vitamins, the pattern suggests that the lipid-transporting ability of the serum is increased during

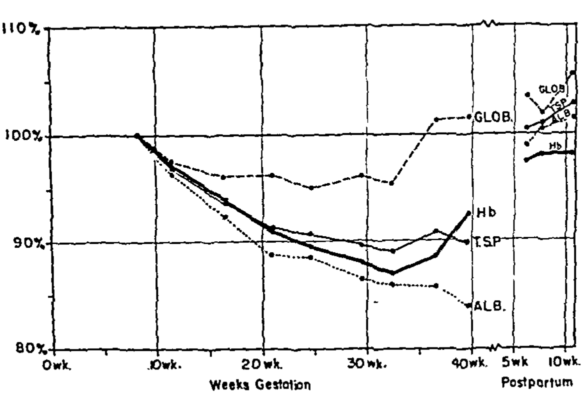

Fig. 1.—Serum protein determinations by weeks of gestation as percentage of 5-to-8-week values.

pregnancy, paralleling the known increase in serum cholesterol value. Again, this alteration was not related to the intake levels of any of the nutrients. 3. The mean serum ascorbic acid concentration decreased slightly during gestation (fig. 3). However, when the dietary intake of vitamin C was above 80 mg. per day, this decline during the prenatal phase did not take place. A further sharp decline occurred post partum in the group of women (71%) who breast-fed their infants. Mothers who fed their infants artifically did not exhibit this postpartum drop-off. This evidence of lactational change appeared at all levels of intake of vitamin C.[4] 4. There was a progressive increase in the absorption and utilization of iron as pregnancy advanced (fig. 4). During the last 10 weeks of pregnancy, the uptake of iron was three times that of the first trimester level.[5]

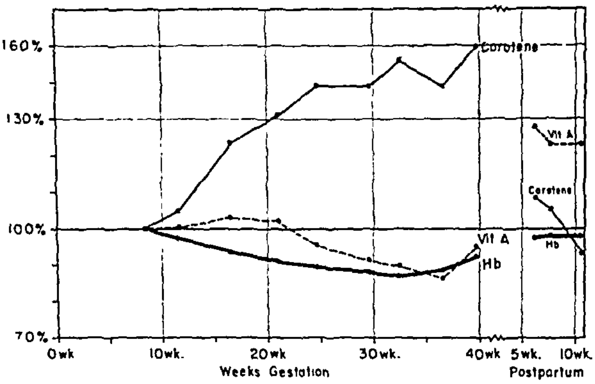

Fig. 2.—Serum vitamin A and carotene determinations by weeks of gestation as percentage of 5-to-8-week values.

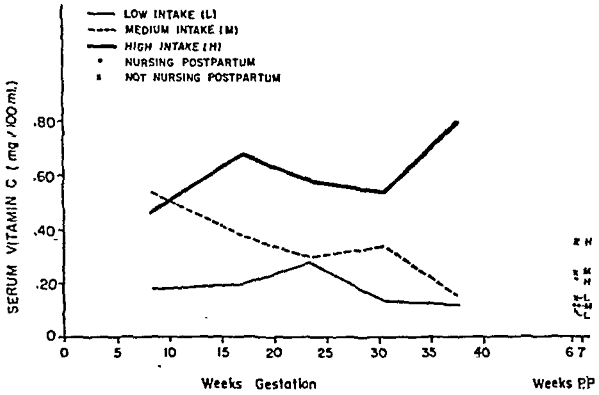

Fig. 3.—Median serum vitamin C levels in consistent intake groups, February to June.

All these alterations reflect metabolic changes of apparently normal physiological origin. To assay biochemical measurements during the reproductive interlude against normal nonpregnant, nonlactating values reveals a lack of understanding of the fundamental adjustments occurring in the pregnant and lactating mother.

Obstetric Complications.—The obstetric and pediatric details of our study have been reported.[6] Suffice it to say that the age and parity relationship of the group reflected a normal pattern. Table 2 demonstrates that this population may be considered as an average, or slightly better than average, obstetric population encountered in the United States. This supports the validity of the generalization of our results.

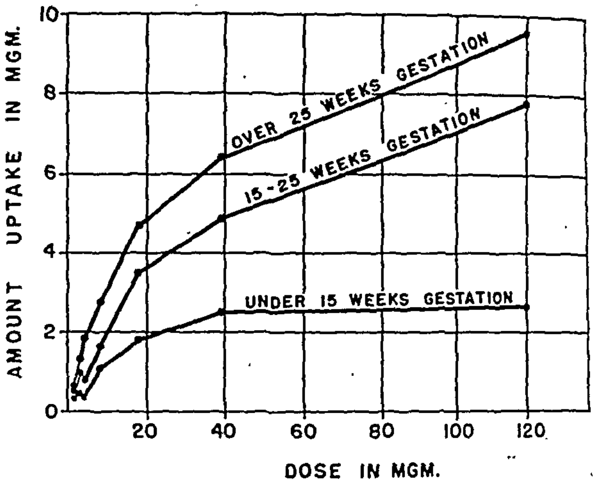

Fig. 4.—Relationship between median amount uptake of iron and dose level during three periods of pregnancy.

The mean height of the women included in the study was 64 inches. The median weight increased from 122 lb. (55.3 kg.) in the first trimester to 139 lb. (63.0 kg.) in the third trimester and then dropped back to 126 lb. (57.1 kg.) at the time of the examination six weeks post partum. Obesity was recorded for 15.7% of the women and varied from 11.5% during the first trimester to 19.3% during the third trimester of pregnancy. Undernutrition was least frequently seen during the last trimester.

Table 2.—*Percentage Incidence of Some Obstetric Complications*

	National Estimates, %*	Vanderbilt Study, %
Anemia	10	11.3
Preeclampsia	6-7	4.5
Eclampsia	0.7	0.5
Placenta previa	0.5-1.0	0.4
Premature separation of placenta	0.3-1.0	1.2
Abortions, spontaneous	10	4.4
Prematurity	6-12	6.7

Neonatal deaths/100 total births†	2.12	2.0

* Widely accepted national or textbook figures.
† Average rate in United States for whites, 1946 to 1950.

As would be expected, the occurrence of dependent edema and varicosities was greater in the latter half of gestation, reaching a peak in the third trimester and returning to more usual levels post partum. No instances of clinically recognizable deficiency disease were encountered during the reproductive interlude.

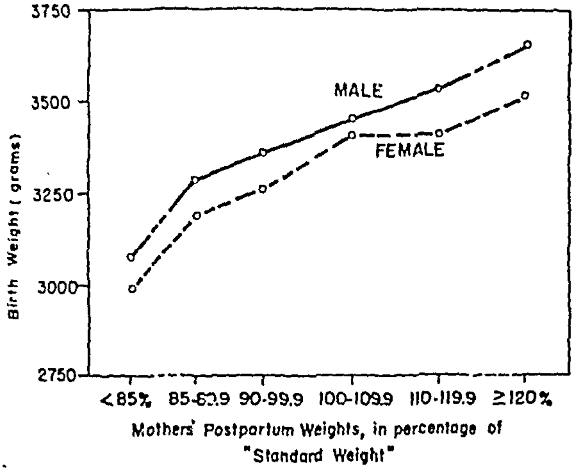

Fig. 5.—Relationship between average birth weight of liveborn singletons and mothers' postpartum weights.

Although the average findings revealed a satisfactory status for the group as determined by dietary, biochemical, and clinical assessment and by obstetric and pediatric performance, some women were underweight or overweight, some ate poorly, some ate excessively, some had low blood and urinary levels of nutrients, and some had obstetric and pediatric difficulties. Further examination of these factors may point out weaknesses in maternal nutriture and provide a basis for establishing nutrient requirements during the reproductive interlude.

Weight Status.—The mean height and weight data by trimester revealed an average woman with an acceptable weight gain for her pregnancy. The underweight group (less than 85% standard weight) recorded the highest dietary intakes and was concentrated in the lower parity groups, for as parity went up, the incidence of underweight declined. In this group, there was an increased frequency of mothers who artificially fed their infants and an increased incidence of prematurity. However, the latter should be anticipated because of the linear relationship between the mother's usual percentage of standard weight and the birth weight of the infant (fig. 5). On the other hand, the underweight group had fewer neonatal deaths and congenitally malformed infants.

The overweight group (greater than or equal to 120% of standard weight) increased as age and parity advanced. Among primigravidas who were under 30 years of age, obesity was observed in 15% of the group, whereas among women over 30 years of age and/or para IV or more 36% were overweight. The overweight group had the lowest recorded dietary intakes. There were significantly higher mean hematological and serum protein and vitamin A values, a threefold increase in preeclampsia, more stillborn children, and a lowered frequency of puerperal morbidity.

Regardless of weight status, there were high weight gainers in all groups—underweight, normal, and overweight—and with all ages of women. These high gainers ate more, particularly during the second trimester, and had more toxemia. It is clear from our data that the physician clamped down on the nutrient intake of both the overweight and high weight gainers. In the obese women with high weight gains, the caloric intake was reduced an average of 900 calories from the first to the third trimester.

Low Hemoglobin Group.—Consideration of maternal and fetal iron needs, iron absorption and utilization, and normal gestational alterations in hematological values is necessary prior to discussing the problem of anemia. In a normal pregnancy, the expectant mother will require the absorption and utilization of 700 to 1,000 mg. of elemental iron for her own needs and those of the fetus. If bleeding is absent during gestation, she is able to conserve about 240 mg. of elemental iron as a result of the cessation of the menstrual loss. In addition, her ability to absorb and utilize iron is enhanced at least threefold during the third trimester when her own and the fetal demands are greatest. Coincident with the changes in circulating blood volume (plasma and red blood cell volume) and increased hemoglobin mass, there is a progressive fall in the mean hematological values until the 32nd to 34th week of gestation and then a significant rise prior to delivery that continues upward during the puerperium. In the case of the hemoglobin, this rise amounts to 0.8 Gm. per 100 ml. during the last six to eight weeks of gestation (fig. 6) and is independent of either nutrient iron intake or iron supplementation. An alternative manner of presenting this rise is shown in figure 7. Here the hematological

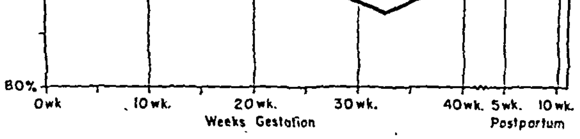

Fig. 6.—Hematological determinations by weeks of gestation as percentage of 5-to-8-week values.

values at delivery are considered the 100% line (not all women delivered at 40 weeks of gestation). It is apparent that the average hemoglobin value at 18-to-20-week gestation is the same as it will be at the time of delivery. These alterations in hematological values were associated with minimal depression of the blood indexes (fig. 8). The decrease in mean cell hemoglobin concentration (MCHC) in the third trimester seems to reflect the increased need for iron by the mother during the latter portion of her pregnancy, a need which was apparent in the pattern of absorption and utilization of this element. The more pronounced decrease apparent in the puerperium is, in all likelihood, the result of blood loss occurring during or after delivery.

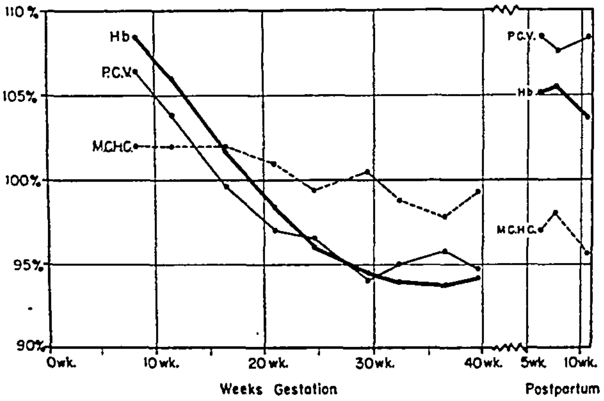

Fig. 7.—Hematological determinations by weeks of gestation as percentage of delivery values.

The "low hemoglobin group" consisted of women who had a hemoglobin level of less than 10 Gm. per 100 ml. On this basis, 232 (11.3%) were so classified—10.5% during the prenatal phase and 0.8% in the puerperium. Of the 196 women who had hemoglobin values below 10 Gm. per 100 ml. in the third trimester, not more than 27% had blood indexes indicative of iron deficiency anemia (table 3). In the total study group of 1,974 there were only 4% who had either a mean cell volume (MCV) or a mean cell hemoglobin concentration (MCHC) indicative of iron insufficiency. Two hundred sixteen of the women developed their low hemoglobin values during the prenatal period (148 in the third trimester), 209 of them having hemoglobin levels above 10 Gm. per 100 ml. at the time of their postpartum examination. The remaining 7 women, plus an additional 16, revealed low hemoglobin values (less than 10 Gm. per 100 ml.) at the time of postpartum examination. From the observations indicating excessive blood loss during the latter half of pregnancy, delivery, or puerperium, it is evident that this group had a conditioned iron deficiency.

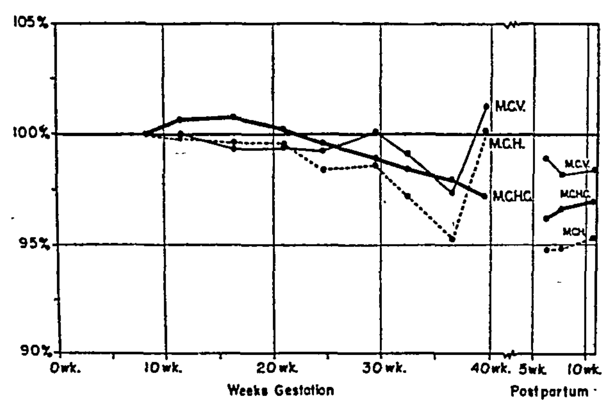

Fig. 8.—Blood indexes by weeks of gestation as percentage of 5-to-8-week values.

The iron and vitamin C intakes of the low hemoglobin group tended to be lower throughout the whole of pregnancy when compared with the intakes of these nutrients by the other groups. However, it is difficult to accept mean intakes of 12 mg. of iron and 46 mg. of vitamin C as deficient values. In the group with hemoglobin levels below 10 Gm. per 100 ml., there was a general lowering of the other blood and serum determinations and an increased incidence of dependent edema in keeping with an increased circulating plasma volume.

Table 3.—*Distribution of Hemoglobin Values*

	Third Trimester Hemoglobin, Gm./100 Ml.				
	<10.0	*10.0-10.9*	*11.0-11.9*	≥12.0	Total
Patients, no.	196	351	569	858	1,974
Patients, %	10	18	29	43	100
Patients with packed cell volume, <30%, %	32	1	0	0	3
Patients with mean cell volume <75 cu. μ, %	19	5	2	1	4
Patients with mean cell hemoglobin concentration <30%, %	27	6	2	0	4
Patients with mean cell volume <75 cu. μ and mean cell hemoglobin concentration <30%, %	9	0	0	0	1

Only 35% of the low hemoglobin group received prescriptions for supplemental iron, and there were no differences in the recorded dietary intakes of iron between women who were supplemented and those who were not. During the third trimester the MCV and MCHC of the group receiving supplements remained significantly lower than in the group not receiving supplements. It was not until the postpartum examination that these hematological differences between the supplemented and the unsupplemented group disappeared. This was particularly noteworthy for patients who had excessive loss of blood during the prenatal period, at delivery, or during the puerperium due to factors such as placenta previa, premature separation of the placenta, postpartum hemorrhage, and, possibly, abortion. At the time of postpartum examination, those patients with excessive blood loss had hemoglobin levels as much as 1.8 Gm. below the values for the total study group. In spite of what was considered unit-for-unit blood replacement and some supplementation with iron during hospitalization, there was failure to replace the patient's blood loss by approximately 500 ml. This is conditioned iron deficiency. The need for iron supplementation in such instances is evident.

Strauss[7] has demonstrated that the children of mothers who have severe iron deficiency anemia at term are themselves anemic at one year of age. Our data[8] on the mothers with low hemoglobin levels at delivery (fig. 9) reveal no differences in the infants' hemoglobin levels during the first year of life when compared with those of infants delivered of mothers in the high hemoglobin group. Although the mothers in our study did not exhibit a major degree of iron deficiency, it is evident that, even if the infant's iron stores at delivery were inadequate, proper infant feeding during the first year of life was corrective and preventative.

Lactation.—The period of maternal lactation has been less well studied than the gestational phase. The obstetrician, pediatrician, and general practitioner alike have tended to overlook, in terms of maternal nutrient needs, the demands of lactation and associated maternal factors.

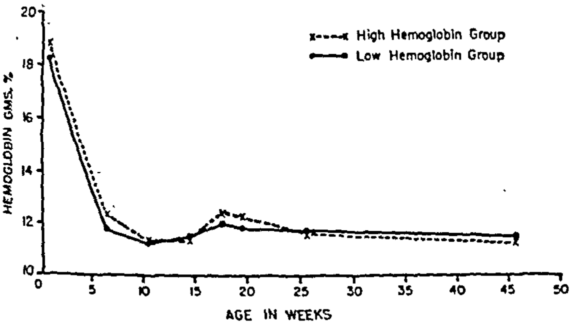

Fig. 9:—Infant hemoglobin determinations.

Certainly the mother's activities are increased. In addition, she must provide large amounts of protein, carbohydrates, minerals, and vitamins, as well as calories, for her suckling infant. These demands must be met by the mother's food sources or body stores. If her dietary intake is not adequate, it is to be expected that some weight loss will occur. Here is a period that requires a great deal more attention by nutritionally minded physicians—general practitioner, obstetrician, and pediatrician.

At the time of discharge from the hospital, 71% of the mothers in our studies were breast-feeding their infants as compared with the national estimate of 65 to 80% of the mothers. Insufficient milk was the commonest cause given for complete or partial supplementation. Nursing increased with parity and decreased among primiparas over 25 years of age and among mothers less than 85% of standard weight. There was more nursing among women with higher levels of intake of calcium, phosphorus, and riboflavin and more artificial feeding among mothers who had received calcium supplementation. These groups reflected differences in milk consumption between those who nursed and those who did not nurse their infants, since mothers who stated they drank fewer than three glasses of milk per day had a higher frequency of calcium supplementation.

Clear biochemical evidence of lactational demand was shown by the lowered postpartum serum vitamin C levels among the mothers who nursed their offspring (fig. 3). This was not dependent on the nutrient intake of ascorbic acid, since it occurred with all intake levels. When the nutrient intake was above 80 mg. per day, the postpartum serum levels could be maintained at approximately 0.3 mg. per 100 ml. This is in contrast to the serum vitamin C levels of 0.6 to 0.8 Gm. during gestation, with the same level of dietary intake.

Detailed analyses of the relationship of various obstetric and pediatric complications to varying levels of nutrient intake and biochemical measurements on maternal nutriture have been recorded previously.[9] In summary, we can say that for our patients nutritional deficiency does not emerge as a primary causative factor in any of the metabolic diseases of pregnancy that are of unclear etiology. The obstetrician who assures his patient freedom from such complications as toxemia and prematurity by advocating an abundant nutrient intake must expect disappointment. However, we do not wish to be interpreted as concluding that nutrition is unimportant in pregnancy. The necessity of insuring an adequate dietary during pregnancy is unquestioned.

Nutrient Requirements in Reproduction

The target level of nutrient intake during the reproductive interlude may not be defined within a narrow range, since it is dependent upon factors such as activity demands, initial weight status, and stage of gestation. It would be unrealistic to allow three women, each 5 ft. 4 in. tall but weighing 100, 122, and 180 lb. (45.4, 55.3, and 81.6 kg.), respectively, to gain the same amount of weight during pregnancy and to recommend the same nutrient intake. In the following discussion, we shall direct our attention to the mean patient from our study—the woman who is neither underweight nor overweight for her height and body build.

Is there evidence that improved nutrition could be expected to prevent the occurrence of gestational complications? In an effort to answer this question, we have examined the groups at the extremes of dietary intake (table 4). The limits of high and low extremes of nutrient intakes were chosen as greater than one or two standard deviations above or below the mean or median values. Two general deductions are pertinent. 1. A more abundant nutrient intake as estimated by caloric level was not associated with a decrease or increase in fetal or obstetric complications, with differences in birth weight or length of the infant, or with physical or biochemical changes (table 5). Similar findings were obtained when the intake estimates were grouped on a basis of protein. 2. When the mother's intake was less than 1,500 calories or less than 50 Gm. of protein, positive correlations were found between certain obstetric and fetal complications and dietary intake during the third trimester. However, the observed increase in incidence of these obstetric and fetal conditions appeared to be responsible for the lowered intakes and not vice versa.[9d]

TABLE 4.—*Approximated Nutrient Intakes, Means or Medians, and Ranges, of Any Trimester*[*]

Nutrient†	—2 S.D.	—1 S.D.	Mean	+1 S.D.	+2 S.D.
Total calories	1,000	1,500	2,100	2,750	3,250
Protein, Gm.	40	50	72	90	110
Calcium, Gm.	0.25	0.75	1.10	1.50	2.00
Iron, mg.	6	10	13.5	18	22
Thiamine, mg.	0.7	1.0	1.4	1.9	2.2
Riboflavin, mg.	0.5	1.5	2.5	3.5	4.5
Niacin, mg.	4.0	8.0	12.0	16.0	20.0
	2½%	16%	Median	84%	97½%
Vitamin A, I.U.	1,000	3,000	6,000	11,000	19,000
Vitamin C, mg.	20	40	60	100	160

* Ranges are 1 or 2 standard deviations above or below mean or median equivalents.

† Values are rounded to fit interval groupings of coded material.

Keeping in mind the modern woman's desire to remain trim, her living pattern, the apparent reduced activity of the expectant mother during the third trimester, the physician's desire to limit weight gain, and the nutritional demands of both mother and infant, this study does not provide evidence to indicate that dietary intakes greater than the average reported or greater than the allowances of the National Research Council will bestow protective benefits during pregnancy. A dietary that will provide the recommended levels of nutrients is readily attainable from food sources in all sections of the country without the need of supplementation. During lactation, on the other hand, less extensive evidence clearly indicates an enhanced caloric expenditure or loss of nutrients for the nursing mother.

* Laboratory levels for given caloric groupings.

† Laboratory values missing in approximately 2% of cases.

We realize that prophylactic broad-spectrum supplementation is commonly prescribed for both private and clinical obstetric patients throughout the country. We use the word "supplement" meaning "to add to, to bring up to adequate levels," rather than "therapeutic." An examination of the label of reputable prenatal preparations shows that the manufacturer's suggested daily dosage will provide from two to five times the National Research Council's recommended allowance for the individual minerals and vitamins. The general routine use of such dosages is extravagant, needless medication. When the obstetrician is concerned that his patient is not obtaining from food sources amounts of minerals and/or vitamins equal to the National Research Council's recommended allowances, simple dietary instruction will usually be corrective. Failing this, supplementation should be aimed at a level that will bring the individual up to the recommended allowances.

Except among women with iron deficiency anemia, we have been unable to find any significant difference in the incidence of maternal or fetal abnormalities or in the clinical nutritional assessment of the groups who received supplements (iron, calcium, or vitamin B complex) and the groups who did not receive supplements. In this instance, as would be true with any nutritional deficiency disease of demonstrable etiology, supplementation is of undisputed value. A less clear situation is present with ascorbic acid nutriture. Although it is apparent that one can maintain serum vitamin C levels during the prenatal period with intakes above 80 mg. per day, some postpartum decline occurring as a result of lactation cannot be prevented. If it is protective to keep serum levels up and if food sources do not provide 80 to 100 mg. of vitamin C, it may be desirable to provide supplements.

Summary

Observations on a total obstetric clinical population have been made. We believe that the findings of this study are widely applicable. Alterations in the patterns of dietary intake and biochemical values during the reproductive interlude revealed fundamental physiological changes in the pregnant and lactating mother. There was a decrease of approximately 200 calories in the average intake between the second and the third trimester. This was associated with a similar decrease in the consumption of most of the individual nutrients.

The change in blood constituents fell into four patterns: (1) a decline during the first 32 to 34 weeks of gestation followed by a postpartum rise; this was present for the mean hematological values, total serum protein, and serum vitamin A, and the urinary excretion of thiamine and riboflavin; (2) a progressive increase during pregnancy followed by a postpartum decline; this pattern was exhibited by serum carotene, tocopherol, and the urinary excretion of N′-methylnicotinamide; (3) a slight decrease in the mean serum vitamin C levels during gestation followed by a further sharp decline post partum among lactating mothers; and (4) a progressive increase in the absorption and utilization of iron as pregnancy advances.

The effects of underweight and overweight, maternal low hemoglobin levels, and lactation on maternal nutriture are described in relation to obstetric and pediatric performance. From conception through parturition and lactation, maternal nutrition should provide adequate amounts of those nutrients that are essential for the mother's maintenance and the growth and development of the fetus. From the present study, it is clear that dietary intakes, greater than the Recommended Dietary Allowances of the Food and Nutrition Board, will not bestow protective benefits during pregnancy. It appears that the recommended standards for calories are too high for the expectant mother of today. A dietary that will provide the essential nutrients is readily attainable from food sources. The common obstetric routine of broad-spectrum nutritional supplementation is questioned, both as to need and as to dosage level. It is apparent that, for the effective use of supplements, the physician must understand the normal physiological changes associated with the reproductive interlude.

This study was supported by grants from the Nutrition Foundation, Inc., the International Health Division of the Rockefeller Foundation, the U. S. Public Health Service, the Tennessee Department of Public Health, and Distillation Products, Inc.

PREVENTIVE MEDICINE

AT ONE TIME, preventive medicine was synonymous with public health. Nowadays it is an integral part of total medical care. Not so long ago, preventive medicine was thought to be limited to sanitation and other forms of environmental and regulatory control. Today the term prevention in medicine applies not only to immunizations but to the avoidance of sequelae and recurrence as well as the prevention of communicability.

Communicability is not limited to contagion. The personal physician must prevent the spread of symptom-complexes to other members of the family. He must prevent seemingly unrelated ill-effects on persons associated with the patient. These ill-effects may arise merely because of the cultural and environmental changes associated with having a sick person around, although they have no direct connection to the specific illness. Lastly, the physician must be interested in adverse effects—economic, social, and especially emotional—that can arise as side-effects of being sick.

How much time can a physician spend doing preventive medicine, when his patients demand so many of his curative skills? The answer to such a question might be as much as the immediate care of the sick will allow. But, if the factor of health promotion is considered rightfully as part of the prevention of disease, the average practitioner spends a great deal more time and effort than the public, or even he himself, supposes.

There are many concepts to consider in the practice of preventive medicine. Primarily, there is the aspect of patient acceptance. Secondarily there is the matter of what diseases or illnesses can be prevented. In the first instance, how many people, in apparent good health, seek out their family physician strictly for the purpose of maintaining their "well" state of being? A survey conducted seven years ago implied that only 5 out of every 100 patients seeking medical care or advice were primarily interested in preventing future disease. The remainder had acute (to the patient) medical problems requiring immediate and specific care. After such care the patient usually declines to continue having medical attention.

As to the matter of which diseases offer applicable preventive techniques, it might be said that wherever the etiology is known, or even suspected, there eventually will be a means of avoidance. Other than communicable (micro-organism) diseases, such generalizations include nutritional illnesses, allergic manifestations, occupational conditions, accidents, and certain psychiatric syndromes, to name but a few.

Many physicians have tried to entice well patients to have their eyes examined for glaucoma, to have their urine tested for diabetes, or in the past, before x-rays became secondary to tuberculin testing as a case-finding procedure, to have a "free" chest examination. Who takes advantage of such preventive techniques? Too often, not the man who is coughing. Nor the person whose mother had diabetes. Nor the woman who is having difficulty seeing. These people, like so many others, seem to be more afraid of learning something is wrong than they are of preventing serious consequences. They have been taught, through publicized advances of medical science, that there would be a cure should the disease ever really take hold. Fear of finding out is greater than the publicized fear of actually having a malady.

A physician cannot force any form of medical care on the public. While some legislative acts require utilizing various preventive practices, such acts do not project their over-all value in terms the average person can understand. The recent laxity in poliomyelitis immunizations seems to confirm this point of view. Perhaps a future job will be to promote the idea of total medical care on a personal basis, to include seeking preventive medical care from the physician's office. Every disease or illness that is prevented allows that much more time to devote to the sick.

THE GENERAL PRACTITIONER'S AWARD

The House of Delegates of the American Medical Association at the 12th Annual Clinical Meeting in Minneapolis on December 2 named Dr. Lonnie A. Coffin of Farmington, Iowa, the general practitioner of the year. He was presented with a gold medal and citation by Dr. Gunnar Gundersen, President of the American Medical Association. Dr. Coffin, who is the first Iowan to receive this honor, was born on a farm in Clark County, Missouri, in 1890 and moved to Iowa at the age of 5. He was a member of the last medical class to be graduated from Drake University in Des Moines. After a year of internship at Iowa Methodist Hospital in Des Moines he established a general practice in Farmington. Except for two years of military service in World War I he has served his community continuously for 44 years. Mrs. Coffin died last year, but he is fortunate in having two married daughters, both living in Farmington, and four grandchildren.

Lonnie A. Coffin, M.D.

Although his practice keeps him busy, he has taken time for civic affairs, serving on the school board for 15 years, serving two terms on the city council, and taking an active part in the local post of the American Legion of which he was the first commander. In addition to being a member of the county and state medical societies and the American Medical Association, he is a member of the local Chamber of Commerce and the Iowa Academy of General Practice. He has served on the board of trustees of the Iowa State Medical Society and was its president in 1956. Although he calls himself just an ordinary country doctor his patients refuse to accept this designation. Their esteem for him was summed up by one who said, "There might be doctors who have done just as good and just as much—but none has done more any better."

LET US PUT AMEF "OVER THE TOP"

It is gratifying to learn that during 1957 the medical profession contributed more than four million dollars to medical education. Nearly one million dollars was contributed through the American Medical Education Foundation, with the balance consisting of direct grants or gifts to the schools or through their alumni organizations. In recent years there has been a steady increase in the number of physicians giving such financial assistance to the schools as well as in the total amounts made available through the American Medical Education Foundation or by direct gifts.

This is the time of year when final decisions must be made by all in regard to tax deductible contributions for 1958. There are only a few days left in which it is possible to make a gift in support of medical education through AMEF that will aid in bringing the contributions from the profession for 1958 to a new record. In order to achieve this new goal in support of the medical schools and for your convenience, The Journal has bound an envelope in the advertising pages in the back of this issue.

Please write out a check for your gift to medical education through the American Medical Education Foundation and forward it today in this envelope. Let us complete 1958 with a record support of medical education by the medical profession, a matter of professional pride, and a genuine challenge to others.

CHANGE OF ADDRESS

If you change your address please notify The Journal at least six weeks before the change is made. Include the address label clipped from your latest copy of The Journal, being sure to clearly state both your old and new address. If your city has Postal Zone Numbers, be sure to include this Zone Number in your new address.

ORGANIZATION SECTION

HIGHLIGHTS OF 12TH CLINICAL MEETING

Bold approach and action to bring improved medical care within the reach of more and more older persons highlighted House of Delegates actions early this month at the American Medical Association's 12th Clinical Meeting. The A. M. A. policy-making body of 198 Delegates made its stand clear through reports and resolutions (among 19 considered) covering aspects of low family income, indigent care, prepaid health insurance, "relative value schedules," and medical care plans. While all of these points reflect the medical profession's concern for personal health generally, the House actions in Minneapolis Dec. 4 showed a distinct emphasis on the health needs of a growing population of aged persons.

In other significant fields, the Delegates expressed their views on federal medical services, disaster preparedness, osteopathy, the "free choice of physician" principle, expansion of medical education facilities, and a re-examination of A. M. A. objectives and basic programs. Dr. Gunnar Gundersen of LaCrosse, Wis., President of the A. M. A., sounded the keynote for the meeting in his opening address Dec. 2 when he said:

> While we fight hard to preserve basic principles and objectives which are essential to good medical care, we also must be alert and adaptable to the changing times in which we live. . . . The time has passed for policies based on generalities, platitudes and flag-waving. The time has passed for medical crankiness, complaint, arrogance and pigheadedness—wherever they might exist. The time has passed when we can fight our battles simply by quoting George Washington, Thomas Jefferson and the rest of the founding fathers. . . .

Following Dr. Gundersen on the rostrum, Minnesota Governor Orville L. Freeman told the Delegates:

> You certainly have the right to oppose [Forand-type] legislation if you believe it would be harmful to your profession. You have the duty to oppose it if you believe it would be harmful to the public. But if you do oppose it you also have the responsibility of helping to work out an alternative program to meet the need that we all know exists and becomes more serious every day. . . . Senior citizens need better care.

Scope of Meeting

The year-end Clinical Meeting is designed to help the family physician meet his daily practice problems. This was accomplished in the Minneapolis Auditorium through reports from nearly 200 experts in various fields of medicine who brought him up to date on rapidly changing developments—and through 100 scientific exhibits, 130 technical exhibits, closed-circuit medical television (on a 9 by 12 ft. color screen), motion pictures, lectures, and panel discussions (including a conference via under-sea telephone cable with physicians in Southampton, England). The A. M. A. met previously in Minneapolis in 1928.

Registration included 2,658 physicians and 2,561 medical students, nurses, technicians, and guests—for a total official attendance of 5,219.

The General Practitioner of the Year award was presented to Dr. Lonnie A. Coffin, aged 68, of Farmington, Iowa. Except for two years of military service during World War I, he has been a key figure in his community for 44 years—delivering 2,500 babies (including 2,000 in the home), leading in civic and recreational activities, serving on the city council and the local school board, and playing vigorous roles in religious, veteran, and medical society affairs.

Earlier issues of THE JOURNAL carried some advance reports of the Clinical Meeting as well as brief statements of Trustees and officers. Future issues will contain an abstract of the proceedings, which eventually will be presented fully in pamphlet form. Following are summary high points of House of Delegates actions:

Oldsters, Fees, Insurance

The House adopted a report from its Council on Medical Service, urging that:

> . . . physicians everywhere expedite the development of an effective voluntary health insurance or prepayment program for the group over 65 with modest resources or low family income; that physicians agree to accept a level of compensation as full payment for medical service rendered to this group, which will permit the development of such insurance and prepayment plans at a reduced premium rate. This recommendation has been studied and restudied by the Board of Trustees, and has received its wholehearted endorsement.

In a related action, the House decided to face the "very important problem" of relative value studies. Relative value studies are not fee schedules. Rather, they are attempts to show (by unit or point designation) the relationship between time, competence, effort, experience, and other factors required to perform one professional service as compared with those required for other professional services. In accepting a Committee on Medical Practices report calling for relative value studies, the House of Delegates agreed that:

> Unless medicine does undertake this activity, it may be done by others who are less qualified. . . . The House of Delegates approves in principle the conducting of relative value studies by each constituent medical association rather than a nation-wide study or series of regional studies. . . . The nomenclature, descriptions and code numbers of the California Relative Value Study (almost identical with those of Kansas and Iowa) can well be accepted as a national format. . . . No unit values and/or dollar values are to be used or suggested.

The Delegates adopted a resolution authorizing the Council on Medical Service to sponsor "at the earliest practicable date" a Congress on Prepaid Health Insurance where plans may be formulated for "offering sound and constantly improving voluntary health insurance to the citizens of our nation." The House also approved a set of "Suggested Guides for Medical Society Sponsored Voluntary Prepayment Medical Benefit Plans."

On the matter of prepaid health insurance for elderly persons, the Delegates accepted a reference committee report which noted that Blue Shield Medical Care Plans "presently have a special committee studying seven distinct approaches to this problem. Many private insurance companies are also removing the 65-year age limit for benefits."

The House also recommended that Congress amend the Social Security Act to permit states to combine the present four public assistance medical programs into a single one.

Medical Care Plans Report

The long-awaited report of the 15-member Commission on Medical Care Plans was received without discussion on the floor of the House, although discussion at a reference committee hearing lasted for two hours. In deciding to defer action on the three and one-half year study until the Annual Meeting in Atlantic City next June, the Delegates noted that "the weight of testimony" in reference committee hearings "indicated that many members had not had an opportunity to study the report and, therefore, were unable to render an opinion at the present time." The House directed that, meanwhile, the Board of Trustees invite state medical associations to reply (by April 8 to Executive Vice-President F. J. L. Blasingame at A. M. A. headquarters in Chicago) to the following questions:

1. Acknowledging the importance of free choice of physician, is this concept to be considered a fundamental principle, incontrovertible, unalterable, and essential to good medical care without qualification?
2. What is or will be your attitude regarding physician participation in those systems of medical care which restrict free choice of physician?

The Commission suggested a definition of "freedom of choice" as "the right of the individual to exercise, without restraint, selection among alternatives." The Commission report adds: "The medical profession subscribes to, supports, and strives to attain complete acceptance and application of this principle of freedom of choice." The Commission's suggested definition of third parties was "mechanisms which, for any reason, enter into the relationship between the patient and his physician."

In its long study, the Commission on Medical Care Plans has explored the operation of various types of plans through which persons receive the services of physicians, the effect of these plans on quality and quantity of medical care, and the legal and ethical status of arrangements used by various plans.

Aleson Committee Report

The House accepted two recommendations, disapproved a third, and modified a fourth recommendation of its Committee to Study A. M. A. Objectives and Basic Programs. The Delegates also agreed with the special Committee, headed by Dr. Lewis Aleson of Los Angeles, that it should be disbanded. The Committee was appointed a year ago to modify recommendations which had their origin in the findings of a management consultant firm. Recommendations adopted this month in Minneapolis were that the Board of Trustees "give serious consideration to opening the publications of the Association to a free and open discussion of socioeconomic problems applicable to medicine" and that consideration be given to amending Article II of the A. M. A. constitution with the following substitution:

> The objectives of the Association are to promote the science and art of medicine and the betterment of public health and an understanding of the socioeconomic conditions which will facilitate the attainment of these objectives.

The Aleson Committee recommendation which was disapproved dealt with the proposed creation of a Council or Committee on Socioeconomics for a three-year period. The House decided this would not be necessary in the light of plans already under way to develop such a division based at A. M. A. headquarters.

Although the House accepted an Aleson Committee recommendation that the Board of Trustees "establish a mechanism which will assume the responsibility for promoting active liaison with each national medical society," a subsequent sentence was modified to read:

> In the scientific fields the role of the A. M. A. *should be primarily that of leadership*, but every endeavor should be made to bring about coordination of the special fields of scientific interest of the other national medical organizations.

Other House Decisions

The House of Delegates also made decisions on the following topics:

Fund Solicitations—Adopted a resolution requesting the Board of Trustees to arrange a "top-level conference" with voluntary health agencies, the United Funds, and other parties interested in the raising of funds for health causes—with the view of resolving "misinterpretations and other difficulties in this area."

Administrative Reorganization—Accepted and praised a Board of Trustees report which detailed a reorganization of the Headquarters staff into seven divisions and which noted that "extra effort is being made to coordinate the activities in the Washington and Chicago offices, and the over-all direction will come from Chicago."

Licensure of Paramedical Groups—Went on record as encouraging the voluntary registration of persons in fields allied to medicine who assist physicians, and opposed the extension of governmental licensure and governmental registration.

Osteopathy—Disapproved a resolution which would establish the sovereignty of relationships between medical societies and the osteopathic profession in their respective states. At the same time, the Delegates asked the Judicial Council to report next June, if possible, on past pronouncements of the House with respect to osteopaths and applicable state laws.

Amphetamines and Athletes—Authorized the Board of Trustees to allow continuation of a Committee study of this subject "in view of the complexity of the problem" and to submit a final report at the Atlantic City meeting.

Civil Defense—Adopted a resolution urging that:

—The A. M. A. recommend that discussions "be started with the view to developing a plan whereby reserve units and individuals can be used to supplement civil defense operations."

—Consideration be given "for the rapid training of civilians" to fill the places of medical reservists.

—A plan be explored for the recruitment, training, and use of former medical personnel who have no further military obligation "so that their services may be utilized for civil defense purposes."

Service Membership—Adopted a resolution of the Council on Constitution and Bylaws, urging that all county medical societies "make every effort" to provide a type of membership for armed forces, Public Health Service, and Veterans Administration physicians which will enable them to become active members of state medical associations and the A. M. A.

Social Security for Physicians—Recognized a resolution indicating that 45.7% of the membership of the Ohio State Medical Association replied "yes" last October to a survey question, "Should physicians be included in the federal social security program?" The House voted that detailed results of the poll be transmitted to the A. M. A. Board of Trustees "for its information and for the information of any of the Councils or Committees of the Association concerned with this matter."

Medicare—Noted curtailment of this federal program and recommended that "the A. M. A. encourage the re-establishment of services under the free choice principle to accomplish the original intent of the Medicare Act."

Poliomyelitis—Endorsed a Board of Trustees report called for renewed public education efforts to secure the minimum of three poliomyelitis vaccine injections.

Korean Children in U. S.—Urged that the Public Health Service, the State Department, and Congress be alerted that some Korean children adopted in the United States are suffering from communicable diseases which are antibiotic resistant and "increase the seriousness of this public health threat."

International Medical Year—Expressed support for a proposed International Medical Year, similar in purpose to the International Geophysical Year.

Commendation of Dr. Austin Smith—Heard Dr. John Galbraith of New York introduce the following resolution:

> WHEREAS, The House of Delegates of the American Medical Association has learned with great regret of the resignation of Dr. Austin Smith as Editor of THE JOURNAL of the American Medical Association; and
>
> WHEREAS, Dr. Smith has rendered outstanding service both to the American Medical Association and to the American public, in his former capacities as Secretary of the Council on Pharmacy and Chemistry, as Director of the Division of Research and more recently as Editor; and
>
> WHEREAS, the scientific activities of the American Medical Association are its most important functions; and
>
> WHEREAS, a scientist of the caliber of Dr. Smith will be most difficult to replace, therefore be it
>
> *Resolved,* by the House of Delegates of the American Medical Association assembled in Minneapolis December 2 to 4, 1958, that it expresses to Dr. Smith, first its sincere regret at his resignation; second, its gratitude and appreciation for his long years of devoted, loyal and efficient service; and third its best wishes to him for long life, health and happiness; and be it further
>
> *Resolved,* that this resolution be spread upon the minutes of the meeting, published in THE JOURNAL of the American Medical Association and a copy be sent to Dr. Smith.

Other Meeting Highlights

The Board of Trustees appointed Dr. W. Linwood Ball of Richmond, Va., as a Trustee for six months, to temporarily fill the vacancy created by the death last Nov. 19 of Dr. Warren W. Furey of Chicago. Dr. Ball will also continue to serve as A. M. A. Vice-President.

A conference on Federal Medical Services Dec. 1 covered such topics as medicare, education and research in veterans' medical care, and the future of Hometown Care Programs for veterans.

In a brief ceremony before the opening session of the House of Delegates, the American Medical Education Foundation received checks totaling $248,659. Later, the A. M. A. added its contribution of $100,000.

DR. AUSTIN SMITH RESIGNS

Dr. Austin Smith, Editor of THE JOURNAL since Dec. 1, 1949, has tendered his resignation and it was accepted by the Board of Trustees, effective Dec. 15th. Dr. Smith had served also as director of editorial policies for the A. M. A.'s nine monthly specialty journals. He joined the American Medical Association in February, 1940, as a medical consultant. In September, 1942, he was made secretary of the Council on Drugs and in 1946 was named, also, director of the Division of Therapy and Research.

Dr. F. J. L. Blasingame, the Executive Vice-President, said, "The American Medical Association accepts Dr. Smith's resignation with regret and is grateful to him for his many years of service. Every good wish is extended to him in the years ahead."

COUNCIL ON MEDICAL SERVICE

MEDICAL CARE FOR THE INDIGENT IN 1958

On June 15, 1957, the Committee on Indigent Care of the Council on Medical Service published in THE JOURNAL a series of 52 questions and answers concerning current legislation governing medical care programs for recipients of public assistance (old age assistance, aid to the blind, aid to the permanently and totally disabled, aid to dependent children). In October, 1957, and May, 1958, the Committee published Supplementary Reports 1 and 2 to that study, bringing the material up to date in the light of the 1956 and 1957 Social Security Amendments, effective July 1, 1957.

On Aug. 29, 1958, the President approved the 1958 Social Security Amendments (H. R. 13549), which again change the methods of financing and administering public assistance medical care, effective Oct. 1, 1958. The following report is therefore issued to inform the medical profession concerning the federal laws now governing public assistance medical care programs.

Background of Program

1. *How was medical care provided for public assistance clients prior to July 1, 1957?*

   The state was free to choose its own method. It could pay for public assistance medical care from public assistance funds, with limited federal participation in the cost, either as part of the money payment to the assistance recipient or, since 1950, through payments to the providers of medical services—"vendor payments." ("Medical services" is interpreted to include physicians and hospitals, nursing homes, pharmacists, dentists, and other auxiliary health services.) The state could also, if it so desired, provide medical services for its indigent entirely from state and local funds, using all the federally matched public assistance funds for money payments to the assistance recipients for their other basic needs.

2. *How did the 1956-1957 amendments, effective July 1, 1957, change this situation?*

   The 1956 amendments established a separate matching formula for vendor medical care payments, under which the federal government would reimburse half the state's expenditures, up to a maximum state expenditure of $6 per adult and $3 per child per month (average). All public assistance expenditures for medical care not included within these limits were subject to federal reimbursement only if spent as money payments to the assistance recipients.

   The 1957 amendments allowed the states to choose between this formula and the one in effect prior to July 1, 1957 (the effective date of the change).

3. *What were the results of these amendments?*

   Almost all states benefited financially from the separate matching formula. However, some states which had established relatively comprehensive medical care programs on a vendor payment basis found that, because of the $6 and $3 limitation, they would have to curtail the vendor portion of their programs to obtain maximum federal participations.

   Other states, in order to obtain the additional federal funds "earmarked" for public assistance vendor payments, found it necessary to revise their administrative operations.

   These amendments and the federal funds authorized did, however, encourage some states having no statewide public assistance medical care program to initiate a formal program for public assistance recipients with encouragement of these federal funds.

A. M. A. Policy

4. *Did the American Medical Association take a position on these amendments?*

   In December, 1956, the House of Delegates of the A. M. A. adopted the "Guides for Medical Societies in Developing Plans for Tax-Supported Personal Health Services for the Needy." This policy statement included the recommendation that the methods and amounts of payment for personal health services in such programs should be determined in conference between the responsible state and local government agencies and representatives of the providers. The new formula, by placing restrictions on federal funds for vendor medical care payments and requiring that all other public assistance funds be spent as money payments, in effect limited the state's freedom of decision as to the method of payment. In June, 1958, the A. M. A. House of

---

Members of the Committee on Indigent Care are Drs. John Flack Burton, Chairman, Oklahoma City; A. J. Bowles, Seattle; I. Jay Brightman, Albany, N. Y.; E. P. Coleman, Canton, Ill.; Wesley W. Hall, Reno, Nev.; E. A. Ockuly, Toledo, Ohio; Dean W. Roberts, Chicago; Mr. R. M. Hilliard, Consultant, Chicago; and Mr. Nelson B. Neff, Consultant, Reno, Nev. Staff members are Mr. George W. Cooley, Secretary, and Mr. James H. Fleming, Research Assistant.

Delegates reaffirmed its 1956 position and advocated the return to the states of all the decisions as to methods of payment.

5. *Are the 1958 amendments in accordance with this A. M. A. policy?*

Yes, insofar as they return to the individual state the decision as to the method of payment of public assistance funds for medical services.

Changes in Law

6. *Do the 1958 amendments merely cancel out the 1956 and 1957 changes in the law?*

No. There are changes in the maximum amounts eligible for federal matching, the method by which the total state expenditure eligible for matching is calculated, and the proportion of the cost to be met by the federal government. Several new items have also been added: Extension of the public assistance programs to Guam (not previously included), the authorization of payments to legal representatives of assistance recipients, and the establishment of a special Advisory Council on Public Assistance comprising representatives of employers, employees, program administrators, specially qualified persons, and the public. (These last two changes will not be discussed here, since information concerning them is insufficient to discuss their medical significance.)

7. *Will any of these changes directly affect indigent medical care programs?*

As the law now stands pending the issuance of any regulation changes by the Bureau of Public Assistance, Social Security Administration, Department of Health, Education, and Welfare, it appears that the medical care situation has been returned to its pre-1957 status. Each state can set up its program to use public assistance funds entirely for money payments, or for both money and vendor payments, with no financial advantage attached to either arrangement influencing its decision. However, since matching changes will probably bring more federal money into the programs in most states, there is a potential increase in the total state expenditures for public assistance which may lead to augmented medical services as well as increases in the basic maintenance budget.

8. *May expenditures still be made for medical care only?*

Yes. The federal law and regulations provide for participation in medical payments for persons who are in the categories covered by these programs and do not need a money payment, but who are eligible for public assistance because of inability to pay for medical care.

Matching Amounts

9. *What changes have been made in the determination of expenditures eligible for federal reimbursement?*

The maximum amount matchable per person has been changed in all four programs, and it is now based on average expenditures rather than on the actual amount expended for each individual.

10. *Is the "maximum amount matchable" the same as the amount of the federal share?*

No. The "maximum amount matchable" refers to the amount of state expenditures to which the matching formulas are applied. The federal government reimburses a portion of this cost; whatever is spent by the state over this limit receives no federal reimbursement.

11. *What is the maximum amount matchable per person under the new legislation?*

The federal government may participate in state expenditures up to a limit of $65 per person per month for recipients of aid to the aged, blind, and disabled, and up to $30 per person per month for recipients of aid to dependent children.

12. *How does this differ from the previous maximums?*

Prior to Oct. 1, 1958, there were actually two matching formulas. Under the basic formula, the federal government shared in the state's monthly expenditures up to a limit of $60 per person in the aid to the aged, blind, and disabled programs and up to a limit of $32 each for one dependent child and the adult responsible for his care and of $23 for each additional dependent child in the same home. Under the vendor medical care payment matching formula, the federal government shared in state expenditures up to a limit of $6 per adult and $3 per child.

If the state chose to utilize both formulas, the basic formula applied to money payments only and the $6-and-$3 formula to vendor payments only; if it did not utilize the $6-and-$3 formula, the basic formula applied to the combined money and vendor payments.

Averaging Provisions

13. *Are the new matching maximums applied to state expenditures in the same way as prior to Oct. 1, 1958?*

No. Prior to Oct. 1, the maximum in the basic formula was applied to each individual's money payment while the $6-and-$3 formula was based on the average vendor payment per person on the assistance rolls. Under the new amendments, all public assistance expenditures in a given program are averaged monthly against the total number of recipients in that program.

For example, under the earlier system, if one old age assistance recipient had a money payment of $40 and a vendor payment of $4 and another had a money payment of $80 and a vendor payment of $8, the money payments could not be averaged, but the vendor payments could if the $6-and-$3 formula were used. Thus, if both formulas were in use, $40 and $60 of the money payments would be eligible for federal matching under the basic formula and $6 and $6 (average of $4 and $8) under the vendor payment formula. If only the basic formula was in use in the state, the amounts eligible for federal matching would be $44 and $60.

Under the current law, all payments would be averaged ($44 plus $88 divided by 2 = $66) and $65 of this average payment would be eligible for matching.

14. *How will this affect the operation of "pooled funds" for medical services?*

For some years, a number of states have operated "pooled funds" set up to distribute medical expenses among all assistance recipients. In this system, a set amount from each recipient's grant is paid into a special fund for medical costs, while payments out of the fund are made in proportion to care provided. Thus, a recipient might receive a money payment of $55 and have $5 paid into the fund in his behalf, so that all expenditures in his behalf would come within the individual $60 maximum—and yet the recipient might have an amount much larger than $5 paid out of the fund for medical services he received.

Since the $6-and-$3 formula for vendor medical care payments was itself based on an averaging of medical expenditures against the total number of assistance recipients in a program, there was less reason for a "pooled fund" in most states utilizing this new formula.

Under the current law, since all public assistance expenditures, both money and vendor payments, are averaged for federal matching, there would appear to be few states which would gain any financial advantage by maintaining a "pooled fund." However, it may possibly provide administrative advantages in some states insofar as it would enable them to separate medical expenditures from other basic maintenance items and, perhaps, maintain a reserve to meet commitments with providers of services. There appears to be no legal obstacle to such a fund and a number of states are planning to continue using this mechanism.

15. *May expenditures under all four programs be combined and averaged against the total public assistance caseload?*

No. The four public assistance programs remain distinct entities, which may even be administered by different state agencies, and separate accounts must be maintained for each. A separate average expenditure must be calculated for each program.

Federal Participation

16. *Does the federal share of public assistance expenditures remain the same as under prior formulas?*

Only in those states which have a per capita income above the national average; in other states, the federal share will increase.

17. *What was the federal share of expenditures prior to Oct. 1, 1958?*

Under previous formulas for aid to the aged, blind, and disabled, the federal government reimbursed ⅘ of the first $30 expended per recipient by the state under the basic formula and ½ the remainder up to the individual matching maximum of $60. If the state also utilized the $6-and-$3 formula, the federal government reimbursed ½ the average vendor payment up to a state expenditure of $6 and participated in only so much of the basic $60 maximum as was made in the form of money payments.

For dependent children, the federal share was 14/17 of the first $17 per recipient plus half the remainder up to the maximums of $32 each for the first child and the caretaker in a home and $23 for each additional child. If the state also utilized the $6-and-$3 formula, the federal share was ½ the vendor medical care payments up to a state expenditure of $3 times the number of children and $6 times the number of adults on the ADC rolls. The basic formula would then apply only to money payments.

18. *How has the federal reimbursement been calculated since Oct. 1, 1958?*

The expenditures in each public assistance program, including both money and vendor payments, are totaled monthly and averaged against those receiving money payments plus those in whose behalf only vendor payments are made during that month. The first part of the formula for determining the federal share remains the same as prior to Oct. 1, 1958: The federal government repays state expenditures at ⅘ of the first $30 per recipient per month (average) in the aid to the aged, blind, and disabled programs, and at 14/17 of the first $17 per recipient of aid to dependent children. The second part of the formula, covering the federal share of average expenditures between $30 and $65 and between $17 and $30, the new maximums, is, however, no longer 50% for each state, but may vary from 50% to 65% of the state expenditure. This varying share is related to each state's per capita income, so that the poorer states receive a proportionately larger federal reimbursement.

19. *In how many states will the federal share be increased by this system?*

The federal government will pay more than the previous 50% in 33 states. In 19 states, it will pay the maximum percentage under the act, 65%.

20. *How is federal participation determined outside the continental United States and in Alaska?*

The law specifies that the federal percentage in Alaska and Hawaii shall be 50%, without regard to the per capita income.

In the Virgin Islands, Puerto Rico, and Guam (included in the program for the first time), federal participation is set at a flat 50% of monthly expenditures up to $35 times the number of recipients of aid to the aged, blind, and disabled, and $18 times the number of aid to dependent children recipients. The law also sets an annual limit on federal reimbursements for these three areas of $8,500,000 to Puerto Rico, $300,000 to the Virgin Islands, and $400,000 to Guam.

Effect on State Financing

21. *How will these new formulas affect the proportion of federal support for state programs?*

It seems probable that the combination of averaging expenditures and increasing federal participation for low income states will mean an increase in federal reimbursement in almost every state. The Bureau of Public Assistance estimates that, if state expenditures continue at their present levels, the increased federal share will amount to about 198 million dollars per year.

22. *Are any states likely to receive less federal reimbursement under the new formula?*

It would be possible, but appears unlikely in most states, since this loss could occur only in high income states which had been making maximum payments to each individual on the rolls.

Future Developments

23. *Has the medical profession taken any stand on increased federal participation in this program?*

No. As previously noted (question 4) the American Medical Association has stated that the method and amount of payment for medical services for the needy should be determined at the state or local level, and in conference with representatives of the providers of such services. In accordance with this policy, the A. M. A. has not found it appropriate to specify any level of funding as necessary or adequate either for indigent medical services or for the entire public assistance program. Such decisions should be made by local authorities on the basis of the local situation.

24. *What is the probable effect of these amendments on indigent medical care programs?*

Two factors may influence the development of such programs: The restored freedom of decision as to allocation of funds for the states, and the increased federal share in the costs in most states. The first factor will allow the individual states to increase or decrease their vendor payment programs as they will, without being influenced by concomitant increases and decreases in federal aid. This may result in the restoration of some vendor payment programs curtailed during the past year. It is unlikely that this freedom will cause the discontinuance of many programs unless there is continued strong local opposition, since few such programs are eliminated once begun.

The second factor, the increase in federal support, may lead to increase in public assistance programs, particularly among the low income states. It is difficult to predict which direction such increases may take, since there is pressure on some of these states to provide a more adequate payment to meet basic nonmedical costs. However, the greatly increased interest in medical care programs among state and local government officials generally, and among welfare officials in particular, may mean some increase in this type of service to the indigent.

Further Information

Since the Social Security Amendments of 1958 did not become law until Aug. 29, 1958, to become effective Oct. 1, 1958, there has, as yet, been little time for program planning by the various states. The Committee on Indigent Care of the Council on Medical Service will continue to report on significant changes as they occur; those desiring further information should write to the Council office, 535 North Dearborn Street, Chicago 10, Illinois.

NOTE: The 1958 amendments also affect the OASDI and Maternal and Child Welfare programs; changes in these programs are not included in this report.

MEDICAL NEWS

ARKANSAS

Dr. Riggin Wins Award.—Dr. John T. Riggin, associate dean of the University of Arkansas School of Medicine, Little Rock, has been given the first annual award of the Arkansas Conference of Tuberculosis Workers "for outstanding work in the control of tuberculosis in the state." He was given a plaque signifying his achievements and those of his colleagues in the establishment and operation of a chest clinic at the University Medical Center and for other statewide activities in the management of tuberculosis. The clinic, organized in July, 1956, provides a means for diagnosing and evaluating patients with suspected tuberculosis and gives outpatient clinic treatment to those not hospitalized in sanatoriums. The clinic provides follow-up care of patients released from sanatoriums and provides the mechanism for training medical students in the diagnosis and treatment of tuberculosis. Dr. Riggin reported that the clinic treated 876 patients in the first two years of its operation. Of these, 99 were referred and/or admitted to either the Booneville or McRae State Tuberculosis Sanatoriums. Another estimated 100 patients were given outpatient therapy at the Medical Center. The clinic sees only indigent patients except in those instances when private physicians refer patients to the Medical Center for specific diagnosis or treatment.

CALIFORNIA

Dr. Rytand Named Bloomfield Professor.—Dr. David A. Rytand was named the first Bloomfield Professor of Medicine at Stanford Medical School. The appointment was revealed at a Big Game reunion luncheon for medical alumni marking the school's 100th anniversary. The professorship honors Dr. Arthur L. Bloomfield, emeritus professor of medicine, who retired in 1954 and who is now engaged primarily in adding to his writings on internal medicine.

School of Medicine Consolidates in San Francisco.—For the first time since the earthquake and fire of 1906, the whole University of California School of Medicine is located at the University of California Medical Center, San Francisco. The freshman medical students who enrolled were the first to receive their basic instruction in anatomy, biochemistry, and physiology in the new, 14-story second unit of the Medical Sciences Building on the San Francisco campus. The first-year courses previously were given on the Berkeley campus, and the departments that teach them completed their move to San Francisco during the summer. This move permits the entire medical curriculum to be offered on a single campus and has made possible an increase from 78 to 100 in the first-year class. It also provides teaching and research space for other Medical Center departments, and it houses the Medical Center Library, and auditorium, and an animal tower. The new unit also provides additional teaching and research space for the School of Pharmacy, the division of oral biology of the School of Dentistry, the Cancer Research Institute, and the departments of medicine, microbiology, parasitology, pathology, pharmacology, and radiology in the School of Medicine. About 176,000 square feet of floor space are housed in the new Medical Sciences unit, which cost $5,773,649. Construction began in 1955. Another major teaching and research building is scheduled for construction beginning in 1960. To be called the Health Sciences Instruction and Research Building, it will extend toward Mt. Sutro from the rear of the Medical Sciences Building. The 10-million-dollar structure is designed to help many Medical Center departments.

COLORADO

Emergency Hospital Unit for Civil Defense.—A 200-bed civil defense emergency hospital was received by the University of Colorado Medical Center, Denver, from the federal government to expand facilities in the event of a civilian disaster and to serve training and educational purposes. Robert L. Denholm, Colorado University Medical Center administrator, said the unit weighs 13 tons and consists of more than 400 separate items. Delivered Nov. 17, the unit will be stored at the Medical Center and will be used to familiarize medical, nursing, and other personnel with its use. In the event of a civilian disaster, the hospital will be set up at the Medical Center and used on a temporary basis. The equipment received includes: a 15-kilowatt generator, a 1500-gallon nylon water storage tank and pump, three operating rooms, a clinical laboratory, x-ray facilities, a sterilizing unit, pharmacy, and central supply room.

CONNECTICUT

University News.—Dr. Kenneth D. Keele, consultant physician at the Ashford Hospital, Middlesex, England, was appointed visiting professor of the

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

history of medicine at the Yale School of Medicine, New Haven, and will be at Yale from October through December. He will work with Dr. John F. Fulton, Sterling Professor of the History of Medicine, in teaching medical and other university students in history of medical research. Dr. Keele is honorary secretary of the section on the history of medicine of the Royal Society of Medicine of London.

ILLINOIS

Hospital Lecture.—The fourth lecture in the ninth annual North Shore Hospital lecture series on "Emotional Forces in the Family" will be held at the hospital, 225 Sheridan Road, Winnetka, Jan. 7, 8:00 p. m. "The Role of Children in the Family" will be discussed by Dr. Sidney Berman, assistant clinical professor of psychiatry, George Washington School of Medicine, Washington, D. C. The Commission on Education of the American Academy of General Practice has approved these lectures for category II credit. All physicians and allied professional personnel are cordially invited to attend.

Personal.—The Illinois State Medical Society has announced that it has selected Dr. Mark Greer, of Vandalia, as the "Outstanding General Practitioner for 1959" and that a plaque emblematical of the honor will be presented to Dr. Greer at the annual meeting of the society in Chicago next May.——Dr. Arthur G. Baker, Pittsburgh, has been appointed director of Lake County Health Department. Previously Dr. Baker was director of the Allegheny County Health Department, served for two years as deputy director of the Pittsburgh Department of Health, and for five years was chief of the section of local health service in the Michigan Department of Public Health.

Chicago

New Building for Medical Center.—An addition to Chicago's West Side Medical Center has begun and Dr. John J. Sheinin, president of Chicago Medical School, has announced that the 10-story, block long, 110,000-square-foot building will be erected at a cost of 4 million dollars. It will have complete facilities for intensive research in biophysics, behavioral science, infectious disease, allergy arthritis, experimental surgery, experimental medicine, metabolism, endocrinology, biochemistry, hematology, cardiology, and oncology. Completion of this new building, the first of the Chicago Medical School's 10-acre campus of buildings, is scheduled for the fall of 1960. The new campus is being developed to include a College of Physicians and Surgeons, a research hospital, nurses' residence, student quarters, and faculty housing. When the new institute is completed it will provide research facilities for over 400 scientists, doctors, technicians, and postgraduate students. The new building will be air conditioned, with special climate control in the animal quarters, and is being provided with pneumatic tube systems and closed circuit TV. Large seminar rooms and exhibit halls will be on the first floor.

INDIANA

Annual Lecture Series.—The Alpha Tau Chapter of the Phi Delta Epsilon Fraternity will hold its annual lectureship series Jan. 30 in the Indiana University School of Medicine Auditorium, Indianapolis. The guest speaker will be Dr. Thomas Gucker, III, medical supervisor of the Rehabilitation Center of the Orthopaedic Hospital of Los Angeles and associated with the faculty of the University of Southern California. His subject is "Rehabilitation—Points of Emphasis."

MAINE

Laboratory Dedicated to Hospital Pathologist.—The Maine Medical Center honored Maine General Hospital's first pathologist, Mortimer Warren, by dedicating its remodeled and enlarged laboratory in his name. Dr. Warren became the first full-time pathologist at the hospital in 1922 and was still active at the time of his death in 1944. The medical staff in donating money to help remodel the laboratory voted to name it in his honor "for his outstanding service to the hospital, his profession and the people of Maine."

MASSACHUSETTS

Medical History Meeting.—The Benjamin Waterhouse Medical History Society will meet at the Massachusetts Memorial Hospital, Boston, Jan. 5, when Donald H. Fleming, Ph.D., visiting professor of history, Harvard University, and professor of the history of science, Yale University, will speak on "Inoculation Controversy of 1721." Reservation for dinner may be made by calling KE 6-8600. All interested are invited to attend the medical history session.

New Building for Mental Patients.—Medfield State Hospital played host on a tour of the new George O. Clark Reception Building. Built at a cost of $2,250,000, the four-story building is designed for the care of mental patients. The main feature is that it centralizes the admission department, the medical and surgical unit, social service, and continued treatment. The new structure will house 196 patients. This is Medfield State Hospital's first new building since 1914. The Clark Building has two complete operating rooms; a physiotherapy laboratory; ear, nose, and throat, eye and foot clinics; cystoscopic room; pharmacy; x-ray laboratory; and electroshock and insulin treatment suites. The building is named for Dr. George O. Clark, who served 36 years as trustee and as chairman of Medfield State Hospital's board of trustees from 1939 to 1948.

Anniversary for Psychoanalytic Society.—The 25th anniversary of the founding of the Boston Psychoanalytic Society and Institute was held Nov. 30 in Boston. The creative role played by Boston psychoanalysts in the development in the United States of their specialty was featured in an afternoon and evening program, and the relations of the society and institute to the Harvard Medical School and the Boston University School of Medicine, to mental and general hospitals in the Boston area, to child psychiatry, social work, and to the social sciences generally were discussed.

MICHIGAN

Plans Announced for Research Building.—Construction of a $2,500,000 Research Building which will be owned jointly by University Hospitals and Western Reserve University School of Medicine is tentatively set for next summer. This will be the first major expansion of research facilities in more than 30 years. The building was made possible through grants from the U. S. Public Health Service, the Hanna Fund, and Republic Steel. Containing about 100,000 square feet, it will be used principally by the departments of medicine and preventive medicine. The L-shaped building will extend east from Lakeside Hospital. The entire building will have two floors underground, and the main stem will be three stories high and the wing will be four stories. The Public Health Service grant amounted to $1,253,686 and was equaled by private gifts. Republic Steel contributed $40,000 and the Hanna Fund pledged the balance. A second grant of $376,245 is to be used for the remodeling of the School of Medicine. This includes air conditioning the entire building and modernizing research laboratories of the basic science departments. Dr. Joseph T. Wearn, dean of Western Reserve University School of Medicine, said that funds are needed to match this sum.

Kenny Hospital and Rehabilitation Institute Affiliate.—The Elizabeth Kenny Foundation has moved its in-patient facilities to the recently completed $3,500,000 Rehabilitation Institute of Metropolitan Detroit, 261 Brady Street, adjacent to Harper Hospital, according to a joint announcement by E. J. Rollings, executive vice-president of the foundation's Michigan chapter, and Dr. Joseph N. Schaeffer, director of RIMD. The move climaxes an expanding rehabilitation program which the Kenny Foundation has supported, both nationally and locally, for the past several years. In addition to polio, a growing emphasis has been placed on helping victims of other crippling and degenerative diseases. Rehabilitation of the chronically ill and disabled, which number 57,000 in the Detroit area, will be a unified objective of both RIMD and the Elizabeth Kenny Foundation. Services include Rehabilitation Nursing, Physical Therapy, Occupational Therapy, Speech and Hearing, Activities of Daily Living, Medical Social Services, Vocational Counseling, and Psychological Services. Associated with Wayne State University College of Medicine, RIMD will also serve as a training center for doctors, nurses, therapists, psychologists, social workers, and other rehabilitation personnel. The Elizabeth Kenny Hospital has been located in Farmington since 1953. All in-patients and necessary hospital equipment were transferred to the new quarters of RIMD on September 11. The Kenny Foundation, which is supported by the United Foundation and the Michigan United Fund, will continue to operate its new out-patient facility in Ferndale, Mich.

MINNESOTA

Dr. Magath Honored by Clinical Pathologists.—Dr. Thomas B. Magath, head of the section of clinical pathology of the Mayo Clinic from 1946 to 1958, and professor of pathology in the Mayo Foundation, was honored Nov. 4 in Chicago at a dinner meeting of the American Society of Clinical Patholgists and the College of American Pathologists. Dr. Magath received the Ward Burdick award of the American Society of Clinical Pathologists, described as "a gold medal which shall be presented to that Fellow who, in the opinion of the Research Committee, has presented the most meritorious contributions to the science of clinical pathology." Dr. Magath has served as president of the society, the Minnesota State Board of Health, and the Minnesota Academy of Science.

NEBRASKA

Meeting on Indian Health.—Indian health was discussed when Creighton University medical and dental faculty members met with Indian medical, dental, and pharmacy officers from a six-state area Nov. 13-14. Present were Dr. Joseph H. Gerber, medical officer for the Aberdeen Area, Division of Indian Health, U. S. Public Health Service, and members of the Aberdeen Area Medical, Dental and Pharmacy Officers Association, including Dr. Emery A. Johnson, Winnebago, association president. The Aberdeen area includes Nebraska, North Dakota, South Dakota, Minnesota, Iowa, and Wisconsin. The program featured Benjamin L. Lynch, D.D.S., dean of the Creighton University School of Dentistry; Dr. Benedict R. Walske, professor of surgery, Creighton School of Medicine; Dr. Robert P. Heaney, assistant professor of medicine; Dr. Harold Ladwig, assistant professor of neurology; Dr. Robert J. Luby, instructor in obstetrics and gynecology; and Dr. John R. Mitchell, assistant professor of pediatrics. Dr. Richard L. Egen, assistant dean, School of Medicine, spoke at the group's banquet in Sioux City Nov. 13. The two-day continuing education program for health officers was related to the referral system between the Winnebago Indian Hospital, which is diagnostic center for the Aberdeen Area, and Creighton University School of Medicine, Omaha. This system, in conjunction with the United States Public Health Service, helps care for indigent Indians in the area.

NEW YORK

Dr. Duthie Comes to Rochester.—Dr. Robert B. Duthie, of the Institute of Orthopedics, Royal National Orthopedic Hospital, in London, England, has been appointed professor of orthopedic surgery and head of the division at the University of Rochester School of Medicine and Dentistry. Dr. Duthie, who began his new duties on Oct. 1, has had clinical, teaching, and research experience in England, Scotland, and Malaya, where he was on active military service from 1949-51 as a captain in the Royal Army Medical Corps. He received the advanced degree of Master of Surgery with distinction from the University of Edinburgh in 1956, when he was awarded the gold medal for his thesis, "The Histochemistry of the Organic Phase of Postfoetal Osteogenesis." Last year he received the President's Prize of the Societe Internationale de Chirurgie for his experimental work on osteogenesis. Dr. Frederick N. Zuck, associate professor of orthopedic surgery, acting head of the division since the retirement of Dr. Russell P. Schwartz last year, continues as vice-chairman.

New York City

Orchestras for Doctors.—Physicians, dentists, and members of allied professions are invited to become members of two orchestras in New York City. Nonmedical musicians may also join. The Doctors' Orchestral Society of New York rehearses Thursday evenings in the auditorium of the Stuyvesant High School, 15th Street and First Avenue, New York City, at 8:30 p. m. The Brooklyn Doctors' Symphony meets Wednesday evenings in the auditorium of the Brooklyn High School of Home Making at 901 Classon Ave., corner of Washington Avenue, Brooklyn, at the same time. For information write Dr. Benjamin A. Rosenberg, 909 President St., Brooklyn 15: NEvins 8-2370.

Invite Exhibits for Health Exposition.—Manufacturers of drug and medical products, sanitary aids, foods, and other health-related products and services are being invited to participate in the second annual Health Exposition, a health education project of the New York City Department of Health, to be held in the New York Coliseum Aug. 5-15, 1959. The Advisory Council is headed by Morey F. Fields, Ed.D., director of Public Health Education for the New York City Department of Health. An attendance survey at the 1958 show revealed that visitors enjoyed unusual and dramatic exhibits which told an important story. Many of the people interviewed said they would like to see more demonstrations and tests, and more action with either animals or humans participating. For information write the City of New York Department of Health, 125 Worth St., New York 13.

Study of Gastric Cancer.—The New York City Department of Health, five hospitals, and a medical group are conducting a study of gastric cancer involving more than 6,000 persons. The department, hospitals, and group have already examined more than 6,000 selected persons for gastric acidity and found that more than 1,000 of those examined had little or no acid in their gastric juice. Previous studies showed that persons with little or no gastric acidity are three to four times more likely to develop gastric cancer than are persons with normal levels of acidity. The investigators will follow up each of those persons who were found to have little or no gastric acidity to determine whether they will develop cancer. This follow up will take three to five years. The study is being directed by the Bureau of Adult Hygiene of the Department of Health, of which Dr. Abraham Oppenheim is director. Those participating in the investigation are Beth El, Beth Israel, Brooklyn Jewish, Mt. Sinai, and Polyclinic hospitals, the Pack Medical Group, and the New York City Health Department's East Harlem Cancer Prevention-Detection Center. The Pack Medical Group is an organization of private physicians who specialize in cancer.

Dedicate General Hospital.—The new 9-million-dollar Misericordia General Hospital at 600 E. 233rd Street, Bronx, was dedicated Sept. 7, 3:00 p. m. Francis Cardinal Spellman, Mayor Robert F. Wagner, and Bronx Borough President, James J. Lyons, participated in the ceremonies. The new plant will serve the Bronx and lower Westchester. It replaces the original Misericordia Hospital at 531 E. 86th Street, Manhattan, founded by the Sisters of Misericorde 70 years ago. The hospital includes a seven-story general hospital building of 210 beds, a six-story nursing school and residence for 150 nurses, and a three-story shelter for unmarried mothers. On the ground floor of the main building are services facilities. Administrative offices, intern quarters, admitting office, and medical records library occupy the first floor. Outpatient departments, laboratories, and x-ray and emergency departments are located on the second floor. The third floor contains the air-conditioned surgical suite with 74 beds and equipment for all specialized types of surgery. The department of surgery will have a teaching affiliation with the Bronx Municipal Hospital and the Albert Einstein College of Medicine. The obstetrical suite occupies the south wing and central area of the fourth floor, and the north wing provides 40 beds for gynecological patients. On the fifth floor are 43 patient beds and an 18-bed pediatrics department, together with the department of medicine, research laboratory, and the central sterile supply section for the entire hospital. The sixth and seventh floors contain the chapel and convent. Misericordia Hospital is one of 15 general hospitals of the archdiocese affiliated with the Department of Health and Hospitals of New York Catholic Charities.

NORTH CAROLINA

Fatalities from Fires in 1957.—One-hundred and ninety-seven North Carolinians lost their lives in fires in 1957. Burns and other deaths associated with fire are the second most important cause of accidental death in the home, outranked only by falls. Normally, deaths due to burns in North Carolina as well as nationally occur most frequently among persons 65 years of age and older, but, in the state in 1957 more than 33% of the fatal fire accidents involved children under 15 years of age, and most of these were in the preschool age group.

OREGON

New Trudeau Society.—The Oregon Trudeau Society was organized on May 14 as the medical section of the Oregon Tuberculosis and Health Association. The following officers were elected: president, Dr. William Cohen, Portland; president-elect, Dr. Donald E. Olson, Portland; secretary-treasurer, Dr. Walter A. Noehren, Sandy. This brings the number of state Trudeau societies to 38.

VIRGINIA

Dr. Leavell Named Assistant Dean.—Dr. Byrd S. Leavell was named assistant dean of the University of Virginia School of Medicine, Charlottesville. He will succeed Dr. Henry B. Mulholland, who retired at the age of 65. Dr. Mulholland will continue his medical practice and teaching duties as professor of internal medicine.

GENERAL

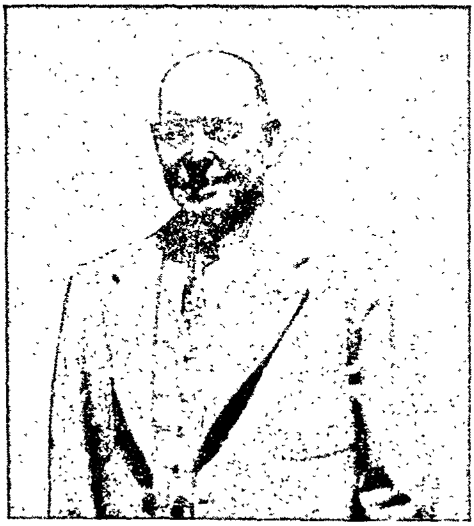
Poison Control Centers.—The American Association of Poison Control Centers was formed in Chicago Oct. 21. Officers elected were as follows: president, Dr. Robert J. Grayson, organizer of the poison control center, Jackson Memorial Hospital, University of Miami School of Medicine; vice-president, Dr. William C. Adams, University of Louisville School of Medicine; and secretary-treasurer, Harry W. Raybin, New York City Department of Health. Membership in the organization is open to persons and organizations interested in poison control programs. The group will have as its aims the stimulation of scientific research and education on toxic substances, assistance to state and local officials and to voluntary agencies in the field of poison control, setting up standards for operation of poison control centers, the provision of information to the public, and the development of information services, insurance liability programs in this area, and warning leaflets.

Child Growth.—Today's children are taller and heavier than those of a generation ago, according to statisticians of the Metropolitan Life Insurance Company. Comparison of measurements for Michigan children made recently with those in 1937-1939 shows consistently higher figures for today's children. Among boys under 9, average heights were greater by a fraction of an inch, and at ages 9 and over by an inch or more. Among girls the difference was an inch as early as age 8. The increase in average weight ranged from more than 2 pounds at age 7 to as much as 13 pounds at age 14. According to statisticians, moreover, the ultimate adult height has increased gradually. Evidence for this is available from data on adults in successive age groups, from father-son and mother-daughter comparisons of college entrants, from Selective Service data for the two World Wars, and from comparative figures on conscripts in various European countries.

Three Researchers Win Nobel Prize in Medicine.—The 1958 Nobel Prize in Medicine has been presented to George Wells Beadle, D.Sc., Pasadena, Calif. and Edward Lawrie Tatum, Ph.D., New York City (jointly), and Dr. Joshua Lederberg, Ph.D., Madison, Wis. Half of the $41,250 award was given to Dr. Beadle, of the California Institute of Technology, and Dr. Tatum, of the Rockefeller Institute, who until last year was at Stanford University, San Francisco. The other half of the prize went to Dr. Lederberg, chairman of the department of medical genetics, University of Wisconsin School of Medicine. Next April he will head a new department of genetics at Stanford University School of Medicine. Drs. Beadle and Tatum reportedly established the new field of biochemical genetics. Dr. Lederberg is known for his discovery that certain types of bacteria reproduce by fusing together. In 1946 Drs. Tatum and Lederberg together received acclaim for their discovery of bi-parental inheritance and sexual reproduction in bacteria strains.

Society News.—The officers of the American Society for the Study of Arteriosclerosis are as follows: president, Dr. James C. Paterson, London, Ontario, Canada; vice-president, Forrest E. Kendall, Ph.D., Welfare Island, New York City; secretary-treasurer, Dr. Otakar J. Pollak, P. O. Box 228, Dover, Del.—The new officers of the American Association for the Surgery of Trauma are Drs. Truman G. Blocker Jr., Galveston, Texas, president; James K. Stack, Chicago, president-elect; Harrison L. McLaughlin, New York City, vice-president; William T. Fitts Jr., Philadelphia, secretary; Raymond Householder, Chicago, treasurer; and Preston A. Wade, New York City, recorder.——The new slate of officers for the **Western Industrial Medical Association, Inc.,** for 1958-1959 is: president, Dr. Edward J. Zaik, Los Angeles; vice-president, Dr. Verne G. Ghormley, Fresno, Calif.; secretary, Dr. Avon C. Remington, Los Angeles; treasurer, Dr. Clarence L. Lloyd, Los Angeles; assistant secretary, Miss Esther Klingsheim, Los Angeles; and assistant treasurer, Mrs. Olga Wolf, Los Angeles.

Wanted by the FBI.—The Federal Bureau of Investigation requests the cooperation of all physicians in the United States in locating Martin L. Manson, who was indicted by the Federal Grand Jury at Los Angeles Feb. 25, 1953, for violation of the National Bankruptcy Act, and who may be under treatment for a tumor. For years Manson operated a tailor shop in Santa Barbara under the firm name of "Martin's." He also established several dry cleaning shops and either abandoned or closed them after a few months, moving to new locations.



Martin L. Manson.

Manson, according to the FBI, is white, 69 years old, 5 ft. 7½ in. tall, weighs about 170 lbs., is portly, has light blue eyes, mixed grey and brown hair, thin on top. He lists his occupation as a tailor, and is proud, boastful, and self-assertive. He is married and has a daughter.

Manson is known to have used the following aliases: Martin Luther Manson, Martin Leonard Manson, Bill Billinger, Martin Martinez, Rue Max Adams, Rue Leonard Adams, L. Martin, M. Leonard, Martin Leonard, Leo Leonard.

Any person having information which might assist in locating this fugitive is requested to immediately notify the Director of the Federal Bureau of Investigation, U. S. Department of Justice, Washington 25, D. C., or the Special Agent in Charge of the nearest FBI Division, the telephone number of which is on the first page of local telephone directories.

Award Honors Elizabeth Blackwell.—Mrs. William Larimer Mellon Jr., of Deschapelles, Haiti, received the first Elizabeth Blackwell award of Hobart and William Smith Colleges, Geneva, N. Y., for "outstanding service to mankind." The award was made by the Rev. Dr. Louis M. Hirshson, president of the colleges, at a special convocation to celebrate the 50th anniversary of the founding of William Smith College for women. It is named to commemorate the life and works of Elizabeth Blackwell, reportedly the first woman doctor in the world, who received her M.D. degree from the medical department of Hobart (then Geneva) College in 1849. The award is a simple gold medal, somewhat larger than a silver dollar. Gwen Grant Mellon, with her husband, Dr. William L. Mellon Jr., established the 75-bed Hospital Albert Schweitzer at Deschapelles, Haiti, in 1956 to serve the hundreds of thousands of people in the 600 square miles of the valley of the Artibonite River. Cost of the hospital, in excess of 2 million dollars, and an annual operating deficit in excess of $250,000 are paid for by the Grant Foundation, a Pennsylvania nonprofit corporation established by Dr. Mellon in honor of his wife, whose maiden name was Grant. Additional gifts to the foundation and its work are received from people all over the world, but its principal source of income has been Dr. and Mrs. Mellon.

Psychiatrists Dedicate Office Building.—The dedication of a new central office building in Washington, D. C., for the American Psychiatric Association was held Oct. 31. Secretary of Health, Education and Welfare Arthur S. Flemming gave the dedicatory address. The American Psychiatric Association was founded in 1844 by 13 physicians under the title Association of Medical Superintendents of American Institutions for the Insane. In 1892, by which time it had about 250 members, the name was changed to the American Medico-Psychological Association. In 1921, when it had 1,000 members, it assumed its present title. By 1950 the association's membership had grown to 6,000; this year it passed the 10,000 mark. The new $300,000 headquarters is a converted town house, owned outrightly by the American Psychiatric Association and made possible by voluntary contributions from its members. It houses a staff of 35. The association provides a wide range of information and consultation services to state governments on mental health and hospital problems; it inspects, rates, and sets standards for mental hospitals; it publishes the *American Journal of Psychiatry*, the magazine, *Mental Hospitals*, and other professional books, reports, and proceedings; it issues the official Nomenclature for Mental Disorders; it administrates special research and conference projects; it furnished information to the public about psychiatry. It is a nonprofit association. The medical director, Dr. Mathew Ross, is the senior staff employee of the association. He took office in September this year, succeeding Dr. Daniel Blain.

CORRECTION

Licensed Foreign-Trained Physicians.—Table 29 entitled "Foreign-Trained Physicians Licensed by State Boards, 1952-1957," published in the State Board Number of The Journal, May 31, 1958, page 622, reported incorrect figures for the year 1956. The total for the fifth column entitled "Examination" for the year 1956 should have been 1,012. This likewise changes the total column in this section to 5,786 and the grand total to 6,738. The figures given for each state are incorrect and anyone referring to this table should consult the Council on Medical Education and Hospitals for the correct figures for each state.

EXAMINATIONS AND LICENSURE

MEDICAL SPECIALTY BOARDS

American Board of Anesthesiology: *Oral.* Phoenix, April 5-10. All applications already on file. Sec., Dr. Forrest E. Leffingwell, 217 Farmington Ave., Hartford 5, Conn.

American Board of Dermatology: *Written.* Several Cities, Oct. 5. *Oral.* Oklahoma City, Jan. 15-18, 1960. The final date for filing all applications is July 1, 1959. Sec., Dr. Beatrice M. Kesten, One Haven Ave., New York 32.

American Board of Internal Medicine: *1959 Schedule—Written,* Oct. 19. Final date for filing application is May 1. *Oral. For candidates in the South and Southwest,* New Orleans, Feb. 3-6. Final date for filing application is Jan. 1. *Oral.* For candidates in the Midwest. Chicago, April 15-18. Final date for filing application is Jan. 1. *Oral.* For candidates on the West Coast. Final date for filing application is March 1. *Oral.* For candidates on the East Coast, Nov. 6-7, 9-10. Final date for filing application is March 1. *Examination in the Subspecialties. Gastroenterology. Philadelphia, April 17-18. Final date for filing application* is Feb. 1. Sec.-Treas., Dr. William A. Werrell, One West Main St., Madison 3, Wis.

American Board of Neurological Surgery: Examination given twice annually, in the spring and fall. *In order to* be eligible a candidate must have his application filed at least six months before the examination time. Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, St. Louis 10.

American Board of Obstetrics and Gynecology: *Part I.* Various parts of the United States and Canada, January 16. Candidates notified of their eligibility to participate in Part I must submit their case abstracts within thirty days of notification of eligibility. No candidate may take the written examination unless the case abstracts have been received in the office of the Secretary. *Oral and Clinical.* Chicago, May 8-19. Formal notice of the exact time of each candidate's examination will be sent him in advance of the *examination dates. Candidates* who participated in the Part I examinations will be notified of their eligibility for the Part II examinations as soon as possible. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: *Written,* qualifying test (Part I), Various Cities, Jan. 26. *Oral.* Philadelphia, June 2; St. Louis, Oct. 6-10. Sec., Dr. Merrill J. King, 22 White St., Rockland, Maine.

American Board of Orthopaedic Surgery: *Part I.* Washington, D. C., Denver, Colorado and Rochester, Minn., Mar. 26-27. Deadline for filing application was Nov. 30. *Part II.* Chicago, Jan. 21-23, 1959. Deadline for receipt of applications was Aug. 15. Sec., Dr. Sam W. Banks, 116 South Michigan Avenue, Chicago 3.

American Board of Otolaryngology: *Oral.* Chicago, Oct. 5-9. Final date for filing application is February. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

American Board of Pathology: Boston, April 16-19. Final date for filing application is Feb. 28. Sec., Dr. Edward B. Smith, 1100 W. Michigan St., Indianapolis 7.

American Board of Physical Medicine and Rehabilitation: *Written, Part I,* and *Oral, Part II.* Philadelphia, June 12-13. Final date for filing application is February 15. Sec., Dr. Earl C. Elkins, 200 First St., S. W., Rochester, Minn.

American Board of Plastic Surgery: *Oral and Written.* Boston, May 9-11. Final date for submitting case reports is Jan. 1. Corresponding Secretary, Miss Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8, Mo.

American Board of Preventive Medicine: *Written. Public Health.* Regional, Apr. 9-11. *Occupational Medicine.* Chicago, Apr. 17-19. *Aviation Medicine.* Los Angeles, Apr. 24-26. Final date for filing application for all three examinations is Jan. 15. Sec., Dr. Tom F. Whayne, 3438 Walnut St., Philadelphia 4.

American Board of Proctology: *Oral and Written.* Philadelphia, September. Final date for filing application is March. Sec., Dr. Stuart T. Ross, 520 Franklin Ave., Garden *City, N. Y.*

American Board of Psychiatry and Neurology: New York City, Dec. 15-16; New Orleans, Mar. 16-17. Training credit for full time psychiatric and/or neurologic assignment in unapproved military programs or services between the dates of Jan. 1, 1950 and Jan. 1, 1954 will be terminated on Jan. 1, 1959. Sec., Dr. David A. Boyd, 102-110 Second Ave. S. W., Rochester, Minn.

American Board of Radiology: *Special Examination.* Cincinnati, Mar. 16-19, 1959. Final date for filing application was Nov. 1. Candidates completing training June 30, 1959 are not eligible for the Spring 1959 examinations. Sec., Dr. H. Dabney Kerr, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery: *Part II.* Houston, Tex., Jan. 12-13; New Haven, Conn., Feb. 9-10; Durham, No. Car.; March 9-10; San Francisco, April 13-14; Indianapolis, May 11-12; Columbus, Ohio, May 14-15. Sec., Dr. John Flick, 1617 Pennsylvania Blvd., Philadelphia 3.

Board of Thoracic Surgery: *Oral.* Los Angeles, April. Final date for filing application is Dec. 1. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2.

American Board of Urology: The oral will be given in Chicago in February 1959. Sec., Dr. William Niles Wishard, Jr., 30 Westwood Road, Minneapolis 26.

DEATHS

Andes, T. Eugene, Gardner, Mass.; Temple University School of Medicine, Philadelphia, 1940; member of the Massachusetts Medical Society and the American Psychiatric Association; certified by the National Board of Medical Examiners; veteran of World War II; served on staffs of hospitals in Harrisburg, Pa., Martinsburg, W. Va., Morganton, N. C., and Lakeland, Ky.; served as assistant superintendent of Gardner (Mass.) State Hospital; died in the Temple University Hospital, Philadelphia, Oct. 10, aged 44, of pulmonary emphysema.

Aszuk, Joseph Charles Ⓜ Wilkes-Barre, Pa.; Temple University School of Medicine, Philadelphia, 1926; veteran of World War I; from 1928 to 1951 on the staff of Mercy Hospital and since 1951 on the staff of the Veterans Administration Hospital, where he died Oct. 18, aged 62, of carcinoma of the bladder.

Bachmann, George William, Smith River, Calif.; University of Buffalo School of Medicine, 1906; veteran of the Spanish-American War; died Sept. 20, aged 79, of a heart attack.

Bernard, Louis Emile Ⓜ Croton-on-Hudson, N. Y.; born in 1898; University of Montreal Faculty of Medicine, Montreal, Que., Canada, 1925; Long Island College Hospital, Brooklyn, 1931; fellow of the American Psychiatric Association; served an internship at the Kings Park (N. Y.) State Hospital and a residency at the Rockland State Hospital in Orangeburg; member of the Association for the Advancement of Psychotherapy, New York Society for Clinical Psychiatry, the Bronx Society of Neurology and Psychiatry, the Westchester Academy of Medicine, and New Jersey Neuropsychiatric Society; served on the staff of the Croton Manor Sanitarium; owner and director of the Stony Lodge in Ossining; consulting psychiatrist at Phelps Memorial Hospital in North Tarrytown, where he died Oct. 23, aged 60.

Beyer, John Andrew II Ⓜ Madison, Wis.; born in Dover, N. J., March 11, 1921; Columbia University College of Physicians and Surgeons, New York City, 1945; interned at the New York Post-Graduate Medical School in New York City and served a fellowship in internal medicine at the New York Hospital; certified by the National Board of Medical Examiners and the American Board of Internal Medicine; instructor of pharmacology at his alma mater from 1946 to 1948; an associate of the American College of Physicians; member of the American Federation for Clinical Research and the Wisconsin Heart Association; member of the Kiddie Camp Convalescent Home for Rheumatic Heart Disease; member of the mobile clinics, Wisconsin Heart Association; member of the board and house physician, Oakwood Lutheran Home; consulting cardiologist, Visiting Nurse Service; member of the staff and chairman of the records committee, Madison General Hospital; director, rheumatic fever clinic, St. Mary's Hospital; chief, cardiovascular section, and captain, U. S. Army Medical Corps, Percy Jones Army Hospital, Battle Creek, Mich., from 1951 to 1953; died in Sioux Falls, S. D., Oct. 18, aged 37, of injuries received in an automobile accident.

Blaine, Edward Smith Ⓜ Los Angeles; Milwaukee Medical College, 1911; served on the faculty of Marquette University School of Medicine in Milwaukee, Northwestern University Medical School in Chicago, and the College of Medical Evangelists in Loma Linda and Los Angeles; specialist certified by the American Board of Radiology; veteran of World War I; died at his home in San Marino, Calif., Oct. 8, aged 75.

Boericke, Oscar Eugene, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1898; an associate member of the American Medical Association; served on the faculty of his alma mater; died Oct. 16, aged 86.

Brown, Joseph Nichols, Campti, La.; Hospital College of Medicine, Louisville, Ky., 1906; member of the Louisiana State Medical Society; past-president of the Natchitoches Parish Medical Association; died in Shreveport Oct. 10, aged 81.

Burch, Newnan Burgess, Hot Springs National Park, Ark.; University of Tennessee College of Medicine, Memphis, 1917; for many years associated with the Wade Clinic; owner of the Burch Clinic; died in the Ochsner Foundation Clinic in New Orleans, Oct. 13, aged 71.

Burke, Joseph Peter, Scranton, Pa.; Georgetown University School of Medicine, Washington, D. C., 1913; veteran of World War I; on the staffs of State, Mercy, and St. Mary's hospitals; died in the Veterans Administration Hospital in Wilkes-Barre Oct. 18, aged 75, of asthma.

Burleson, William Brown Ⓜ Plumtree, N. C.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1915; died Oct. 2, aged 76.

Ⓜ Indicates Member of the American Medical Association.

Butler, Harry M., Hutchinson, Kan.; Ensworth Medical College, St. Joseph, Mo., 1905; served on the staffs of the Hadley Memorial and St. Anthony's hospitals in Hays; died in the Grace Hospital Oct. 10, aged 81, of pneumonia.

Carman, John Thomas, Franklin, Ky.; University of Tennessee Medical Department, Nashville, 1898; an associate member of the American Medical Association; died in the Carter Moore Hospital Oct. 1, aged 88, of heart disease and a fractured hip as the result of a fall.

Charles, Thomas Goodell Ⓜ Beardstown, Ill.; Northwestern University Medical School, Chicago, 1909; chairman of the Beardstown Board of Health; veteran of World War I; died in St. Luke's Hospital, St. Louis, Oct. 10, aged 71.

Chenoweth, Laurence Benjamin Ⓜ Cincinnati; Johns Hopkins University School of Medicine, Baltimore, 1919; served on the faculty of the Cornell University in Ithaca, N. Y., and as director of the department of hygiene and student health service, University of Cincinnati; past-president of the American College Health Association; for three years president of the Phi Epsilon Kappa; joint author of "School Problems," "Personal Hygiene," and other books on hygiene and health; died Oct. 17, aged 67, of coronary occlusion and arteriosclerotic heart disease.

Close, John Harry Ⓜ Minersville, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1935; interned at the Harrisburg (Pa.) Hospital; died in the A. C. Milliken Hospital in Pottsville Sept. 24, aged 51, of hypertensive heart disease.

Coffee, John Young Jr. Ⓜ Huntsville, Ala.; Medical College of Georgia, Augusta, 1947; served in the Korean War and World War II; interned at Jefferson–Hillman University Hospital in Birmingham; formerly resident in pediatrics at the Employees Hospital of the Tennessee Coal, Iron and Railroad Company in Fairfield; served as vice-president of the Madison County Medical Society; died in the Brookhaven National Laboratories in Upton, L. I., Oct. 5, aged 36, of brain tumor.

Council, Melton Downie, Vero Beach, Fla.; Johns Hopkins University School of Medicine, Baltimore, 1911; an associate member of the American Medical Association; veteran of World War I; died in the Veterans Administration Hospital, Richmond, Va., Oct. 5, aged 74.

Creighton, Matthew Eugene Ⓜ Chicago; Loyola University School of Medicine, Chicago, 1925; fellow of the International College of Surgeons; served on the faculty of his alma mater; member and past-president of the medical staff, St. Bernard Hospital; died Oct. 21, aged 59, of coronary occlusion.

Cronin, Herbert Joseph, Cambridge, Mass.; Harvard Medical School, Boston, 1911; member of the Massachusetts Medical Society; died in Boston Oct. 3, aged 69, of bronchopneumonia.

Daniel, Samuel Greene Ⓜ Marshall, Ark.; University of Louisville (Ky.) School of Medicine, 1895; died Oct. 1, aged 90.

Danskin, Melville George, Billings, Mont.; born in Colo, Iowa, Oct. 9, 1883; Northwestern University Medical School, Chicago, 1909; an associate member of the American Medical Association; a past-vice-president of the Montana Medical Association; for many years practiced in Glendive and eastern Montana; appointed county health officer for Dawson County in 1916, serving in this capacity for many years; from 1923 to 1927 mayor of Glendive and served as president of the state public health association and as the first president of the local Kiwanis Club; in 1916 named physician in charge of the Dawson County Hospital, holding that post for many years; died Oct. 11, aged 74.

Davis, James Matheson Ⓜ Wadesboro, N. C.; Columbia University College of Physicians and Surgeons, New York City, 1913; veteran of World War I; on the staff of the Anson County Hospital; died in Denton, Oct. 12, aged 69, of acute coronary occlusion.

Delbaum, Harry, Brooklyn; Long Island College Hospital, Brooklyn, 1935; member of the Medical Society of the State of New York; on the staff of the Unity Hospital; died Oct. 12, aged 49, of coronary disease.

Di Rienzo, George Michael Ⓜ Napa, Calif.; New York Medical College, Flower and Fifth Avenue Hospitals, New York City, 1948; member of the American Academy of General Practice; captain, U. S. Air Force from July 1, 1949, to Sept. 3, 1951; on the staff of the Queen of the Valley Hospital; died Oct. 14, aged 32, of coronary arteriosclerosis.

Dudley, Augustus William Ⓜ Cambridge, Mass.; Harvard Medical School, Boston, 1895; veteran of World War I; fellow of the American College of Surgeons; for many years on the staff of the Mount Auburn Hospital; died in the Westboro (Mass.) State Hospital Oct. 7, aged 90, of carcinoma of the colon.

Dunn, James Ⓜ Davenport, Iowa; Rush Medical College, Chicago, 1904; specialist certified by the American Board of Pediatrics; member of the American Academy of Pediatrics; honorary life member and secretary of the Iowa and Illinois Central District Medical Society, and served as editor of its bulletin; at one time a medical officer in the U. S. Public Health Service; on the staffs of Mercy and St. Luke's hospitals; died in Muscatine Oct. 11, aged 79.

Dusthimer, Oren Isaiah Ⓜ Zanesville, Ohio; Ohio Medical University, Columbus, 1906; honored in June, 1956, when the Muskingum County Academy of Medicine presented him with a 50-year pin; received a certificate of distinction from the Ohio State Medical Association; on the staffs of the Good Samaritan Hospital and the Bethesda Hospital, where he died Oct. 13, aged 82, of rheumatic heart disease and pneumonia.

Ebeling, William Bruno, Brooklyn; Columbia University College of Physicians and Surgeons, New York City, 1914; specialist certified by the American Board of Ophthalmology; fellow of the American College of Surgeons; on the staff of the Brooklyn Eye and Ear Hospital; died in the General Hospital of Monroe County, East Stroudsburg, Sept. 13, aged 67, of mesenteric thrombosis.

Farrar, William Charles, Birmingham, Ala.; Birmingham Medical College, 1908; died Oct. 11, aged 79, of uremia and cardiovascular disease.

Field, Thomas Sullivan Ⓜ Green Cove Springs, Fla.; Dartmouth Medical School, Hanover, N. H., 1910; fellow of the American College of Surgeons; veteran of World War I; on the staffs of Duval County Medical Center, St. Luke's Hospital, and St. Vincent's Hospital in Jacksonville, where he died Oct. 10, aged 72, of bronchiectasis.

Fitzporter, Alonzo Leo Ⓜ Muskogee, Okla.; St. Louis University School of Medicine, 1910; service member of the American Medical Association; retired from the Veterans Administration regional office, in 1954; served most of his career in various veterans hospitals throughout the country; veteran of World Wars I and II; died in Tucson, Ariz., Oct. 13, aged 74, of coronary occlusion.

Frey, Robert David, Allentown, Pa.; Jefferson Medical College of Philadelphia, 1890; died in the Allentown Hospital Oct. 10, aged 90, of uremia and generalized arteriosclerosis.

Friedman, Joseph Ⓜ Baltimore; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1931; member of the American Academy of General Practice; veteran of World War II; died Oct. 4, aged 56.

Frymire, Ewett Waverly Ⓜ Frankfort, Ky.; University of Louisville Medical Department, 1905; died in the Norton Memorial Infirmary Oct. 9, aged 77, of arteriosclerotic heart disease.

Gallagher, James Francis Ⓜ Freeland, Pa.; Temple University School of Medicine, Philadelphia, 1925; on the staffs of the Hazleton State and St. Joseph's hospitals; member of the board of directors of the Hazleton Heart Association; died Oct. 7, aged 58, of coronary disease.

Gallivan, Thomas Humphrey Ⓜ Santa Ana, Calif.; Yale University School of Medicine, New Haven, Conn., 1909; specialist certified by the American Board of Otolaryngology; served on the staffs of St. Francis Hospital in Hartford, Conn., Community and Doctors hospitals in Santa Ana, and St. Joseph Hospital in Orange, where he died Oct. 14, aged 73.

Gibbons, Charles Kimball, Kearney, Neb.; Northwestern University Medical School, Chicago, 1902; past-president of the Buffalo County Medical Society; veteran of World War I; on the staff of the Good Samaritan Hospital; member of the Chamber of Commerce and the Rotary Club; died Oct. 3, aged 81, of gastrointestinal bleeding and shock.

Gleason, Ralph Sidney, Deer Island, Maine; Tufts College Medical School, Boston, 1929; interned at Eastern Maine General Hospital, Bangor; member of the Massachusetts Medical Society; for many years practiced in Wellesley Hills, Mass.; served on the staff of the Newton-Wellesley Hospital in Newton, Mass.; veteran of World War II; died Oct. 13, aged 53, of pulmonary hemorrhage.

Goudelock, John Jefferies, Monroe, N. C.; Medical College of South Carolina, Charleston, 1923; member of the Medical Society of the State of North Carolina; associated with the Ellen Fitzgerald Annex of the Union Memorial Hospital; was found dead in bed Oct. 13, aged 58, of a heart attack.

Grant, William Lee Ⓜ St. Paul, Minn.; Marquette University School of Medicine, Milwaukee, 1955; service member of the American Medical Association; interned at the Illinois Central Hospital in Chicago; served as a captain in the U. S. Army Reserve and as head of the outpatient clinic at Fort Leonard Wood, Mo.; died Oct. 18, aged 29, of coronary occlusion.

Gray, Robert Hollingsworth, Shreveport, La.; Bellevue Hospital Medical College, New York City, 1895; for many years on the staff of the Schumpert Sanitarium, where he died Oct. 5, aged 87, of injuries received when struck by an automobile on Sept. 27.

Hargrove, Henry C., Beckley, W. Va.; Howard University College of Medicine, Washington, D. C., 1908; died Oct. 1, aged 78.

Henry, John Robert, Winston-Salem, N. C.; Leonard Medical School, Raleigh, 1908; medical director of the Winston Mutual Life Insurance Company, a post he held for 39 years; medical director of Safe Bus Company; attending physician at the Kate Bitting Reynolds Memorial Hospital, where he died Oct. 3, aged 74, of gastrointestinal hemorrhage from esophageal varices, and cirrhosis of the liver.

Herbert, William, Dunedin, Fla.; Long Island College Hospital, Brooklyn, 1909; specialist certified by the American Board of Otolaryngology; fellow of the American College of Surgeons; formerly practiced in Brooklyn, where he was associated with the Brooklyn, Bushwick, and Brooklyn Eye and Ear hospitals; died in the Mease Hospital Sept. 26, aged 76, of arteriosclerotic heart disease.

MacBride-Dexter, Edith Ⓜ Sharon, Pa.; born in Grove City, Pa., May 3, 1887; Woman's Medical College of Pennsylvania, Philadelphia, 1910; from 1912 to 1917 physician for girls, Grove City (Pa.) College; appointed secretary of health, Commonwealth of Pennsylvania in 1935, serving until 1939; on Aug. 12, 1938, was awarded Pennsylvania's "meritorious service medal" by the governor, for distinguished service in public health during widespread floods of 1936, and for a progressive program as secretary of health; past-vice-president of the Medical Society of the State of Pennsylvania; for ten years secretary of the Mercer County Medical Society; served as chairman of the advisory board of health, as member of the sanitary water board, state board of medical education and licensure, state dental council and examining board, and state board of undertakers, Commonwealth of Pennsylvania; member of the Pennsylvania Public Health Association and served as chairman of executive committee; from 1935 to 1939 member of the Conference of State and Territorial Health Authorities; member of the Conference of State and Provincial Health Authorities of North America and the Pan American Association of Ophthalmology; at various times vice-chairman, secretary, and chairman of the Secretaries Conferences of Component County Medical Society of the State of Pennsylvania; from 1919 to 1935 on the staff of the C. H. Buhl Hospital, now known as the Sharon General Hospital, where she returned to the staff in 1939; ophthalmologist to the Sharon Plant, Westinghouse Electric Manufacturing Company and National Malleable and Steel Castings Company; died Oct. 11, aged 71, of a heart attack.

McKenna, Henry Joseph Ⓜ Louisville, Ky.; born in Louisville March 30, 1885; University of Louisville School of Medicine, 1910; associated with Mayo Clinic in Rochester, Minn., from July 1, 1912, to Feb. 1, 1915; veteran of World War I; formerly practiced in Kansas City, Mo., where he was president of the staff of St. Mary's Hospital; at one time president of the McKenna Distillery of Fairfield; fellow of the American College of Surgeons; member of the Industrial Medical Association; served on the staff of St. Joseph Hospital and as medical director of the Bendix Products Division of the Bendix Aviation Corporation in South Bend, Ind.; died in St. Joseph Infirmary Oct. 8, aged 73, of peritonitis and pneumonia.

Mateer, Harry Oliver Ⓜ Pittsburgh; Pulte Medical College, Homeopathic, Cincinnati, 1910; Hahnemann Medical College and Hospital of Philadelphia, 1912; for many years associated with the health service of the city schools; veteran of World War I; past-president of the Hahnemann Alumni Association; member of the staff of the Shadyside Hospital, where he died Oct. 1, aged 72.

Mendelsohn, Sidney Norman Ⓜ Cincinnati; University of Louisville (Ky.) School of Medicine, 1929; fellow of the American College of Surgeons; specialist certified by the American Board of Surgery; on the staffs of Our Lady of Mercy Hospital and the Jewish Hospital and Medical Center of Cincinnati, where he died Oct. 4, aged 53.

Meriwether, Ellyson Gwynne Ⓜ Memphis, Tenn.; Memphis Hospital Medical College, 1909; member of the American Psychiatric Association; died Oct. 7, aged 73, of cerebral thrombosis and arteriosclerosis.

Metheny, Samuel, Lincoln, Neb.; Lincoln Medical College of Cotner University, 1902; served on the faculty of his alma mater; died in the Bryan Memorial Hospital Oct. 2, aged 94, of intestinal obstruction and coronary thrombosis.

Noyes, John Russell Ⓜ Brockton, Mass.; Boston University School of Medicine, 1904; fellow of the American College of Surgeons; for many years associated with the Brockton Hospital, where he served as chief of the eye, ear, nose and throat service; consultant, Jordan Hospital, Plymouth; died Oct. 8, aged 82, of cerebral thrombosis.

Nussbaum, Oscar, New York City; Julius-Maximilians-Universität Medizinische Fakultät, Wurzburg, Bavaria, Germany, 1908; an *associate member of* the American Medical Association; died in the Jewish Memorial Hospital Oct. 11, aged 78, of intestinal neoplasm.

Rauch, Harvey Milton, Ormond Beach, Fla.; College of Physicians and Surgeons, Baltimore, 1904; member of the staff of St. Joseph's Hospital and the Falk Clinic in Pittsburgh, where he practiced for many years; died Oct. 1, aged 82, of a heart attack.

Reed, Russel Soule Ⓜ Seattle; Bennett Medical College, Chicago, 1913; died in the Virginia Mason Hospital Oct. 4, aged 70, of myocardial infarction.

Thorndike, W. T. Sherman, Philadelphia; born in Boston Jan. 16, 1893; Harvard Medical School, Boston, 1920; for many years on the faculty of his alma mater; an associate member of the American

Medical Association; member of the Massachusetts Medical Society; past-president and secretary of the Philadelphia Hospital Association and a member of its executive committee; member of the council on administrative practice, Hospital Association of Pennsylvania, advisory committee to the Commission on Blood Banks, Medical Society of the State of Pennsylvania, and on the advisory board of the Hospital Council of Philadelphia; during World War II served as registrar of the Sixth General Army Hospital in Casablanca and Rome; later served as commanding officer of the 154th Station Hospital in Italy and was discharged in 1946 with the rank of lieutenant colonel; interned at the Boston Lying-In Hospital and the Massachusetts General Hospital in Boston, where he was assistant director for many years; managing director of the Germantown Dispensary and Hospital, where he died Oct. 10, aged 65, of cancer of the prostate with metastasis.

Tillman, Isidor R., Brooklyn; University of Buffalo School of Medicine, 1901; an associate member of the American Medical Association; died Sept. 15, aged 87, of pneumonia, cardiac decompensation, cerebral thrombosis, and generalized arteriosclerosis.

Truex, Barbara Mae Binkley Ⓜ Jackson, Tenn.; Vanderbilt University School of Medicine, Nashville, 1942; served an internship at the Barnes Hospital in St. Louis and a residency at the Children's and Cincinnati General hospitals in Cincinnati, Ohio; on the staff of the Jackson–Madison County General Hospital; died Sept. 23, aged 40, of a basal skull fracture as the result of a fall from a horse.

Virden, Charles Edgar Ⓜ Kansas City, Mo.; born in Kansas City April 12, 1895; Northwestern University Medical School, Chicago, 1920; assistant clinical professor of radiology at the University of Kansas School of Medicine in Kansas City, Kans.; specialist certified by the American Board of Radiology, Inc.; past-president of the Jackson County Medical Society which in 1947 awarded him its certificate of merit; past-president of the Missouri division of the American Cancer Society and received a gold medal from the American Cancer Society for his work in connection with the disease; past-president of the American College of Radiology, Missouri State Medical Association, Kansas City Southwest Clinical Society, and the Radiological Society of North America; member of the Kansas City Academy of Medicine and the Industrial Medical Association; fellow of the American Geriatrics Society and the American Association for the Advancement of Science; consultant radiologist for the U. S. Public Health Service and the Parsons Tumor Clinic in Parsons, Kan.; instrumental in establishing the cancer clinic at the Kansas City General Hospital; chief radiologist at St. Joseph Hospital, where he served an internship and where he was associated for many years; died in the Georgetown University Hospital in Washington, D. C., Oct. 3, aged 63, of coronary thrombosis.

Whitely, Seals Leftwich Ⓜ Durant, Okla.; University of Oklahoma School of Medicine, Oklahoma City, 1949; member of the American Academy of General Practice; secretary-treasurer, Atoka, Bryan, Coal Counties Medical Society; served as county superintendent of public health; associated with Durant Hospital; died Sept. 26, aged 37, of teratoma of the mediastinum.

Willmarth, Edwin Hamilton Ⓜ New Castle, Pa.; University of Nebraska College of Medicine, Omaha, 1928; on the staffs of the Jameson Memorial Hospital and New Castle Hospital, where he died Sept. 19, aged 57, of cerebral hemorrhage.

Wilson, Eva McClenahan Ⓜ Mill Valley, Calif.; Northwestern University Woman's Medical School, Chicago, 1894; member of the Illinois State Medical Society; died Sept. 25, aged 88.

Wooden, James Leonidas Ⓜ Clatskanie, Ore.; University of Oregon Medical School, Portland, 1906; veteran of World War I; served several terms on the school board; the citizens of the Clatskanie area honored him with a "Doctor Wooden Day" in August of last year, commemorating 50 years of practice in the community; a fountain in the city park was erected and dedicated in his honor; for many years director of the First National Bank; died in the Emanuel Hospital, Portland, Oct. 7, aged 76, of cancer of the cecum and chest with metastasis and bronchopneumonia.

Zimmerman, Frank Dieffenbach, Schaefferstown, Pa.; Jefferson Medical College of Philadelphia, 1907; an associate member of the American Medical Association; past-president of the Lebanon County Medical Society; president of the Heidelberg Water Company; for many years served as president of the Schaefferstown National Bank, prior to its becoming a branch of the Lebanon Valley National Bank, of which he was director; a charter member of the local Lions Club; on the staff of the Good Samaritan Hospital in Lebanon; died Sept. 27, aged 80, of acute coronary occlusion.

FOREIGN LETTERS

BELGIUM

Lung Cancer.—Prof. J. Firket (*Proceedings of the Royal Society of Medicine of London*) studied air pollution in Liege, an industrial center. He found that the homes of 500 patients with pulmonary cancer were largely concentrated in the center of the city. Many workers were employed in the huge metallurgic establishments just upstream of the city and lived in houses built 10 to 15 years ago. Because of the prevailing wind, the area they all occupied was one of the least polluted by chemical dust, yet the number of workers with pulmonary cancers was fairly large. In contrast, in the center of the area which is surrounded by a horseshoe bend of the Meuse River, immediately northeast of the first area, there were few patients with cancer even though this is a sort of tableland on which dust settles in abundance. There was no industry on the plateau and it has been a pleasant residential area for about 45 years with many trees and occupied by the upper middle class. The extensive dust pollution of this area was not known at the time it was built.

The author was struck by the large number of persons with cancer living in the center of the city and especially in streets beside railways or canals. The attention was drawn to these by their names, "Rue de la gare, Rue de la station, Rue du chemin de fer, and Rue du vicinal." Railway engines were an obvious source of air pollution and steamboats also definitely polluted the air around the docks. In 1955 the incidence of lung cancer in Canada was found to be five times higher among locomotive engineers than among the whole population. Engineers inhaled carcinogenic hydrocarbons either from the sooty exhaust of diesel engines or the smoke of coal-burning locomotives.

In Belgium, too, one can see a striking correspondence between smoke and lung cancer. In the vicinity of factories in Herstal, one can find many men out of work because of cancer, but as the valley runs north the incidence suddenly drops and, at the same time, the smoke disappears. Toward the east the smoke continues and with it the cancer. From five years of research it must be concluded that lung cancer has a complex etiology. Of several factors cigarette smoking is an important, but not an essential, one. Polluted air, and particularly the hydrocarbons contained in soot, appear to be even more important.

BRAZIL

Tetanus Neonatorum.—Dr. Francisco La Scala (*Jornal de pediatria*, vol. 23, September, 1958) reported a series of 56 patients with tetanus neonatorum. He called attention to the low incidence of this disease among Negroes, indicating a racial resistance. Only six of these children recovered despite the use of antitetanic serum and antibiotics. The author advocated as a preventive measure against this complication the immunization of expectant mothers who cannot have the assistance of an aseptic delivery.

Schistosomiasis.—Dr. Luis Rey (*Hospital*, vol. 54, October, 1958) reported that a new focus of schistosomiasis has been discovered within the city of São Paulo. He believed that new foci appear only as a consequence of favorable conditions recently created. Due to the inefficiency of molluscocides and the limitations of chemotherapy, greater emphasis must be placed on sanitary methods of control aimed not against schistosomiasis alone but against all endemic diseases spread through feces and polluted water.

Prevention of Abortion.—Cerruti and Fernandes (*Revista d'obstetricia e ginecologia*, vol. 103, July, 1958) have simplified the technique of interpreting the vaginal smears considering only the eosinophilic index and the progestational modifications. They studied a series of 239 women in the first trimester of pregnancy with threatened abortion, taking one, two, or three smears from each. In 118 patients with a "good prognosis" they had 11% of error with one smear and 6.8% and 5.1% with two and three smears respectively. In 121 patients with a "bad prognosis" the error was 6.6% with one smear and 4.2% with two or three smears. The authors reached the following conclusions. The vaginal smear was of no value as a diagnostic test of pregnancy. In patients with a bad prognosis showing cells indicative of fetal death, this conclusion was invariably correct. The lessening of absence of progestational modifications had a greater prognostic value than the rise of the eosinophilic index. Vaginal smears did not permit differentiation between the phase of ovum death and that of its expulsion. Intensive estrogenic treatment did not alter the appearance of the vaginal smear in pregnancy. An unfavorable vaginal smear found in patients without any clinical signs of abortion had no prognostic value because in such patients pregnancy often proceeded normally.

The items in these letters are contributed by regular correspondents in the various foreign countries.

Statistical study of this material indicated that the progestational modifications had greater value than the eosinophilic index and the examination of a second smear lessened the chances of error and established that within a reasonable range of error it is possible to give a prognosis regarding a threatened abortion. Incipient miscarriage would appear to be due primarily to fetal rather than maternal factors. From a purely clinical point of view it is possible to establish the prognosis of an abortion only when the symptoms and signs become evident. It is then often too late to apply effective preventive measures. The authors found that the pregnandiol level had scant value for the prognosis of threatened abortion because (1) of the relatively low amount of this hormone at the beginning of pregnancy, with little difference between its level at that time and during the secretory phase of menstruation; (2) frequent discrepancy between the expected pregnandiol level and the course of pregnancy; and (3) the great technical difficulty of determining the level. The frog test is easier to make. The repetition of this test is of value for the prognosis of threatened abortion. The vaginal smear is an easy process which can be repeated as required if abortion threatens. Vaginal cytology does not indicate the amount of hormones in the blood but gives a sufficiently accurate idea of the balance between estrogen and progesterone, thus giving advance warning of a hormonal imbalance in patients with threatened abortion.

Polyposis of the Colon.—Dr. Silvio Levy, (*Arquivos de cirurgia clínica e experimental*, vol. 21, 1958) in a series of 67 patients with polyposis of the colon, found carcinoma in 18. One of the most important aspects of this series was the presence of malignant polyps in the first decade of life (25% of the cases). The incidence of polyps in about 6,000 patients was 1.5%. In the diagnosis of the polyp it is important to recognize the lesion, even in asymptomatic patients. X-ray examinations are indispensable for the detection of polyps above the reach of the sigmoidoscope. This higher localization of polyps occurs more frequently than was recognized before the use of the barium enema. The biopsy may be total or partial. The total biopsy represents a complete therapeutic procedure in itself in patients with noninvasive carcinoma. Partial biopsy should never be done if the lesion is small, but it is advisable for polyps measuring more than 1 cm. in diameter, especially if they are sessile or if they present macroscopic signs of malignancy. The operative indications and the choice of the surgical procedure should be based on (1) localization of the polyp, (2) macroscopic appearance of the polyp, (3) microscopic appearance of the previous biopsy specimen, (4) number of polyps and presence of other lesions, (5) age of the patient, and (6) medicosocial factors such as facilities for an efficient follow-up.

The simple excision of the adenoma through an endoscope is indicated for small polyps if the histological appearance does not suggest the presence of malignancy, or for a polyp with a previous biopsy specimen indicating noninvasive carcinoma, grade 1, or carcinoma "in situ." Radical surgical resection is advisable for an invasive carcinoma diagnosed by a previous biopsy or diagnosed after the excision of the lesions, or if the patient cannot be rigorously followed up. For villous adenomas, resection is also preferable. Polyps of the various segments of the colon, which cannot be treated endoscopically, must be explored by laparotomy. It i advantageous always to perform a complete proctoscopy to decide the extent of the resection. If ther is suspicion of the presence of metastases, the examination of fragments of regional lymph nodes i of value. Resection is preferable to the simple excision of the polyps and is a much more complete operation. For sessile adenomas a primary segmental resection is imperative. Villous adenomas should be resected with the segment.

INDIA

Plasma Amino Acids in Malignancy.—G. Y. N. Iyer (*Indian Journal of Medical Research*, vol. 46, July, 1958) studied 42 patients with malignancy to determine the levels of free alanine, glutamine, glutamic acid, glycine, serine, tyrosine, valine, leucine, and isoleucine in the plasma; 18 of the patients were suffering from leukemia, 6 had carcinoma of the stomach, 6 had carcinoma of cheek, 4 had cancer of the uterus, 3 had Hodgkin's disease, 2 had cancer of the palate, 2 had cancer of the penis, and 1 had carcinoma of the prostate. Paper chromatography was used for estimation of the amino acids in the plasma. A rise in the glutamic acid level was seen in all patients. The levels of all the other amino acids except glycine showed a fall, and the level of glycine was not significantly changed except that it was raised in all patients with leukemia. No correlation was observed between the type and location of malignancy and the changes in plasma amino acids.

Plasma Insulin Estimation.—Aiman and Kulkarni (*Indian Journal of Physiology and Pharmacology*, vol. 2, July, 1958) stated that because certain diabetics prove resistant to insulin, insulin deficiency may not be the only cause of diabetes. They estimated the plasma insulin level in 5 nondiabetic and 10 diabetic persons by the rat diaphragm method. Insulin therapy was discontinued for 48 hours and carbutamide therapy for 15 days before the assay of plasma insulin. The postprandial blood sugar level was estimated in each case to exclude any latent derangement of carbohydrate metabolism.

The plasma insulin levels in the nondiabetics ranged from 0.7 to 6.3 milliunits per milliliter. In two diabetics who were middle-aged, whose disease had been discovered within a period of less than six months and who did not require insulin, the plasma insulin levels were within the normal range. Four middle-aged diabetics required insulin and responded well to carbutamide or tolbutamide and showed plasma insulin levels that were lower than normal, but these readings were a little higher than those obtained in two other middle-aged diabetics, one of whom did not respond to carbutamide. The remaining two diabetics who were in a younger age group also showed low plasma insulin levels and an evidence of the presence of an excess of anti-insulin factors in their plasma. Thus juvenile diabetes is probably due to an excess of anti-insulin factors circulating in the plasma, while the diabetes of middle age is more probably due to a deficiency of insulin in the plasma. This method can also be used in selecting patients for carbutamide therapy. In the present series, patients with a moderate concentration of insulin in the plasma showed a good response to this therapy, while those with a negligible insulin content failed to respond.

Cesarean Section.—S. Apteka analyzed a series of 1,344 cesarean sections performed at the Cama and Albless Hospitals, Bombay, from 1930 to 1956 (*Journal of the Association of Medical Women in India*, vol. 46, May, 1958). This series represented 1.4% of all deliveries at these hospitals. All cases of ruptured uterus were excluded from these statistics. The incidence was highest in 1940 and 1942 and lowest in 1951, 1952, and 1953. Contracted pelvis accounted for 73.6% of cesarean sections at these hospitals. Most of the patients who come to these hospitals are poor and undernourished and therefore likely to be underdeveloped and to suffer from rickets and osteomalacia. The incidence of repeated cesarean sections was very low—0.6%. This operation was repeated only in patients in whom it was suspected that the scar of the previous operation might give way. All patients who had a cesarean section at one delivery for an indication which was not present at a subsequent pregnancy were allowed to deliver per vaginum under careful observation. The maternal complications for which cesarean section was performed were eclampsia, essential hypertension, intracranial tumor, infective jaundice, and obstructive cholecystitis. The number of cesarean sections performed for osteomalacic pelvis decreased from 53.5% in the years 1930-1934 to 19.6% in the years 1950-1956. This might be due to improved general living conditions.

Other varieties of contracted pelvis did not show any appreciable difference in their incidence. Placenta previa as an indication for cesarean section was seen to be increasing. During the period 1930-1934, of a total of 170 sections, only 1 was performed for this condition, while during the period 1950-1956, 51 of a total of 418 sections were performed for placenta previa. The classic type of operation was performed on 513 patients (38.2%), lower segment operation on 824 (61.2%), cesarean hysterectomy on 6 (0.5%), and extraperitoneal cesarean section on 1 (0.1%). The number of classic cesarean sections showed a definite decrease in the more recent period. In the period 1930-1934, it was performed on 78.2% of the patients and in 1950-1956, on 15.3%. The number of lower segment sections increased from 21.2% in 1930-1934 to 84% in 1950-1956. The low classic incision was still preferred for some patients, e. g., when dense adhesions with the urinary bladder were present as a result of a previous cesarean section or in some patients with transverse or oblique position of the fetus. The cesarean hysterectomies were all performed for uncontrollable hemorrhage after extraction of the baby, except in one patient who had a carcinoma of the cervix.

The average maternal death rate was 3.9%. Although the maternal death rate has fallen in recent years as a result of the use of antibiotics and blood transfusion, there was not a single death after cesarean section in the earlier period. The cause of death was puerperal infection in 16 patients, and most of these were treated in the period 1930-1934. Shock (operative or due to hemorrhage) accounted for 16 other deaths, and in one patient on whom extraperitoneal cesarean section was attempted spinal shock developed soon after commencement of the operation and the patient died. In two cases death was attributed to the general anesthesia and in three to pulmonary embolism. One patient died of paralytic ileus, and in 13 others the cause of death was a complication of pregnancy. There were 165 fetal deaths in this period, an incidence of 12.3%, and in the period 1952-1956 it was 17.6%. This high fetal death rate was associated with antepartum hemorrhage. Of the 12 stillbirths in this period, 3 were associated with abruptio placenta and 6 with placenta previa. There were 43 neonatal deaths, of which placenta previa associated with pre-maturity accounted for 10. From 1952 to 1956, of a total of 55 deaths, asphyxia was the cause of 21, and 11 of these showed evidence of fetal distress before the section was performed. All of these mothers had had a trial labor. All the babies were asphyxiated at birth and died within the first 48 hours. Eight mothers did not have a trial labor. Their babies were asphyxiated at birth and died within 48 hours, except one who died of bronchopneumonia on the fifth day. In these cases, probably the general anesthesia was responsible for the asphyxia.

JAPAN

Tuberculosis.—Because tuberculosis affects so many young persons, it is one of the nation's most pressing health problems. A government report places the number of cases of active tuberculosis at 3,400,000 and of arrested disease needing close observation at 1,470,000. Patients who know they have the disease but refuse to be treated constitute a dangerous source of infection. Among those with active tuberculosis about 410,000 have open cavities and about 860,000 require sanatorium treatment. Some improvement in the situation in general has occurred in the past five years.

Use of Hospital Beds.—Dr. Hideguki Iwasaki reported that, although the general hospitals and especially the psychiatric hospitals are overcrowded, there is a growing surplus of beds in the tuberculosis sanatoriums. This is partly because with modern improvements in the treatment of tuberculosis the patients can be discharged much sooner than was formerly the case and partly because many patients with tuberculosis cannot afford sanatorium care. At present no provision is made to assist such patients with public funds. Since the general hospitals are best adapted to care for patients with acute diseases and ill adapted for the care of those with chronic illnesses, unoccupied beds in tuberculosis sanatoriums are being used for such patients.

PORTUGAL

Hormonotherapy for Tuberculosis.—Cordeiro Ferreira and co-workers (*Rev. portug. ped.* 21:281-290, 1958) treated a large series of tuberculous patients with prednisone, in a daily dosage of 1 mg. per kilogram of body weight. All patients always received isoniazid and streptomycin as well. Definite improvement was obtained with steroid therapy in patients with tuberculous meningitis, miliary tuberculosis, and pleurisy. Local application of steroids in patients with tuberculous adenitis of the cervical lymph nodes also produced greater improvement than treatment without steroids.

Adrenals and Mammary Cancer.—Frazão and Botelho (*Rev. iber. endocrinol.* 28:433-441, 1958) studied the changes in the adrenals removed from patients with advanced and generalized mammary cancer. The changes in the adrenal cortex and medulla were identical with those seen in the adrenals of animals subjected to stress. In the cortex, the zonal disorganization, spongy appearance, folicular formations, and increase in lipoid and cholesterol content were similar to those associated with hypertensive disease and other conditions of stress. Vacuolar degeneration of the medulla also corresponded to findings seen in animals subjected t stress.

UNITED KINGDOM

Influenza Vaccine.—British experts have produce a live virus vaccine against influenza, which is being tested on volunteers. If it proves effective an safe, it will provide a new protection for the population at large. An attenuated live virus has th advantages over a killed virus that it can be produced much more quickly and is easier to give. A smaller dose suffices. The killed vaccine is injected. The live vaccine can be sprayed into the nose and throat. Because it is more virulent, it should not be given to young children. Work on the new vaccine is proceeding at the National Institute for Medical Research. Promising results with a live virus were achieved by the Russians. The cost of protection is likely to be less than with the vaccines used hitherto, and it offers the least discomfort. Ample supplies of killed virus vaccine, which has been proved to give 60 to 70% protection, are available. Vaccination is especially important for expectant mothers and people suffering from cardiovascular, pulmonary, or metabolic diseases. All such people can be vaccinated under the National Health Service.

Colored Immigrants.—According to an annotation in the *British Medical Journal* of Oct. 4, about 190,000 colored people live in Great Britain. This is about one colored to 250 white, though the distribution of the colored people is notably uneven owing to the greater prospects of employment in the industrial cities. Of these 190,000, about 100,000 came from the West Indies (chiefly Jamaica) and 50,000 from India and Pakistan. Because members of the British Commonwealth are free to come here, no administrative machinery exists to keep a count of their exact numbers. There is no doubt that the current high estimate is a phenomenon of the last decade. Unrestricted immigration from any country, whatever the color of its inhabitants' skins, is likely to cause difficulties when the country they enter is already densely populated. The social evils of slum life are apt to spread and defy attempts at their eradication. Fraud and frustration appear, and the immigrants, uprooted from gay and friendly company, seek ephemeral friendship and sexual solace where they can find it. An additional problem, apparently specific to the migrants from Jamaica, is that in the West Indies marriage has largely given way, through a transitional stage of "faithful concubinage," to outright promiscuity. It is thus not surprising that many half-caste children and some full West Indian babies are found in our orphanages. Indeed a quota of 4 colored children in 10 has already been filled in these orphanages in some parts of the country.

While the social prospects of these population movements are not notably favorable, the strictly biological prospects are obscure. There is a lack of precise knowledge about the long-term implications of the human genetic mixtures taking place in our times, partly because of the relatively slow rate of breeding in the human race and partly because experimental breeding is out of the question. Moreover, it is debatable what, if any, inferences about miscegenation in human populations can be drawn from animal experiments, and in particular whether heterosis, or hybrid vigor, can be detected. All would agree with the society's advocacy of more research into the results of race-mixing, for ease of travel is likely to increase rather than impede it. Nor can anyone doubt the need for more education of people in an appreciation of the qualities distinctive of unlike or alien nations. While the question of whether immigration to Great Britain from Commonwealth countries should be restricted has many features outside the immediate professional interests of physicians, it is one on which they are well equipped to provide evidence, and to judge dispassionately.

Health Insurance.—The Fellowship for Freedom in Medicine has persuaded the British United Provident Association (B. U. P. A.) to launch an insurance scheme to help cover the cost of private treatment by general practitioners. The scheme will become effective in January. While there are already several excellent schemes insuring against the costs of treatment in a hospital as a private patient, private clinic, or nursing home, and of specialist advice or investigation, this is the first insurance scheme to cover the cost of private treatment by a general practitioner. It will be restricted to those already insured under B. U. P. A.'s standard scheme (for such items as private beds and specialist fees) whereby for an additional rate a subscriber may obtain insurance for himself and his dependents for attendance by a private general practitioner and for minor operations. The cost of drugs is not included.

Healing by Clergymen.—The report of the Archbishop's Commission on the Church's Ministry of Healing stated that all healing was divine healing and that healing concerned the whole person as an interrelated amalgam of spirit, mind, and body. One does not treat sickness, one treats a sick person. Many diseases are spiritual in origin and according to the report at least 33% of the patients in hospitals need the ministry of a priest rather than a physician. The Bishop of Coventry, however, stated that healing did not always follow faith, nor was suffering always contrary to God's will. Many public healing services have fostered a false impression that God must heal. It is wrong to assume that death is necessarily a disaster. There is a danger in calling this ministry "faith healing" or even "divine healing." Physicians are just as much the ambassadors of God in His ministry of healing as are pastors and praying laymen. It is right to remind the clergy that they have a ministry of healing, but there is a danger that people may become preoccupied with what they call the ministry of healing to the total exclusion of every other kind of ministry. They must see it in its proper perspective in relation to the total aspect of their ministry.

The Bishop of Lichfield said that the medical profession was ready and anxious to receive a lead from the Church. Later a succession of speakers affirmed their belief in demons. Canon E. G. Burrough of Oxford University said that he was a profound believer in angels, and also in demons. He believed that many of the people who spent their lives in lunatic asylums were possessed with evil spirits rather than suffering from diseases of the brain. The Dean of Windsor said there was nothing in the creeds about belief in angels or demons. He pled for "a reverent agnosticism" on the subject.

Oral Penicillin.—In the *British Medical Journal* of Oct. 11, David Wheatley sent a questionnaire to 180 members of the Northern Home Counties Faculty of the College of General Practitioners regarding penicillin for oral use. Although such preparations have been in use for nine years, the value of this method of administration is still subject to controversy. Wheatley received replies from 85 members. Of these 78 gave penicillin by mouth, 70 used it for both children and adults, and the rest for children alone. The ratio of patients treated orally to those treated by injection over a 20-day period in May was 5:2. These results, coming from varied practices, were probably representative of national custom. This being so, more penicillin may now be given by mouth than by injection. Of the infections commonly treated orally with penicillin, tonsillitis and acute otitis media ranked high followed by acute bronchitis, pneumonia, and boils. These results reflected the common penicillin-sensitive infections met with in general practice, with the exception of severe deep-seated infections, such as carbuncles, which are probably best treated with injections of penicillin.

With regard to the preparations used, penicillin V appeared to be sweeping the field although benzathine penicillin in its liquid form still retained a place in the treatment of children. Combined penicillin and sulfonamide therapy was not particularly popular, only 18 of the 85 using it. Its indications were for such infections as pneumonia or others that failed to respond to penicillin alone. The dosage schedules used showed wide variations; 56 of the doctors gave 60 mg. of penicillin V every three to six hours for children up to 5 years of age and

52 gave double this dose to adults. The dose used for other preparations was two or three times the above for adults. This would seem to reflect fairly accurately the difference between the amount of penicillin V absorbed from the gastrointestinal tract and that of other penicillin salts. A four to five days' treatment for the infections listed was recommended by 66. One physician thought that oral administration was better than injection; 64 found the two forms comparable. Of those who thought oral administration not as good as injection, 2 probably used inadequate doses. More continued to give the drug by mouth rather than by injection despite their impressions of the relative efficiency of the two methods, probably because they found the oral preparation effective enough to allow its advantages to overcome any slightly diminished therapeutic effect. Most general practitioners appeared to be satisfied with the effectiveness of oral penicillin therapy.

Doctors' Plea Fails.—Mr. Maclay, secretary for Scotland, told the British Medical Association (B. M. A.) that he cannot join with them in presenting a special case to the Court of Session on the general practitioners' pay dispute. He had been asked to agree to the presentation of a case to test the validity of the Spens Report and the Danckwerts adjudication on doctors' remuneration. The B. M. A. had taken counsel's opinion and was advised that in Scotland there existed a "special case" procedure for which the consent of Mr. Maclay was necessary. In a letter to the Association Mr. Maclay stated that he made his decision because he believed with the Minister of Health that no contractual obligation existed between the government and the medical profession on remuneration, and because a Royal commission was considering the matter. A spokesman of the B. M. A. said that the rejection of the Association's offer had been made without Mr. Maclay asking to see the Association's draft of the stated case. Mr. Maclay had been less than candid in his reference to the letter of rejection of November, 1956. The letter said that if the B. M. A. was not prepared to accept the Minister's rejection, the matter could be brought before the courts for adjudication. The spokesman added that despite the fact that the suggestion of obtaining a legal decision on the disputed question came originally from the government, the Secretary of State had rejected this approach. It may be that the government is less confident about the probable result of the suggested legal proceedings.

Medical Maneuvers.—Striking advances in the technique of rescuing and treating men wounded in action have been demonstrated by the Royal Army Medical Corps. After a mock nuclear explosion, "seriously wounded" infantrymen were evacuated from the front line by relays of helicopters. Spectators watched the progress of an infantry battalion advancing to forward positions. While still short of their objective the nuclear missile burst on their flank less than a mile away. A smoke mushroom streaked with orange rose 300 ft. over the Surrey pine woods. When it dispersed the battlefield was strewn with "casualties." Survivors among the five highly qualified medical soldiers, who now form part of every infantry battalion, sprang quickly into action giving prompt medical treatment to the wounded. Within ten minutes two of the most severely wounded were being evacuated in a new midget helicopter. Soon larger Whirlwinds from the joint experimental helicopter unit at Middle Wallop brought doctors, medical equipment, and supplies, and evacuated the wounded at the rate of one every three minutes. As a finale the helicopters landed a field surgical team.

Helicopters are still inadequate for large-scale operations of this nature, but a type which Army Medical Services officers said they would like to use for casualty evacuation, the new 48-seat Fairey Rotodyne, made a demonstration run after the exercise. An unusual feature of the exercise was the appearance of 48 women, who made up the first and only field medical company staffed entirely by women. The unit was formed to prove that even if all male physicians and orderlies from a casualty clearing station had to go forward in an emergency, women could carry on.
